The national game law, known as the Lacey Law, passed by the Congress in 1900, gave to the Department of Agriculture certain powers, by which among other provisions no importation of wild animals, birds, or fishes could be made without a permit from the secretary of agriculture.

Two important Federal laws relating to game were passed during the year 1902: (1) An act amending the tariff act so as to permit the importation of the eggs of game birds for propagation, and (2) an act protecting game in Alaska. The Alaska act, which is the first general game law of the Territory, fixes close seasons and prohibits export and sale, though permitting shipment of specimens and trophies for scientific purposes under regulations made by the secretary of agriculture. Legislative sessions were held in less than one third of the States and Territories, but in nearly every case some changes were made in laws for the protection of game. General game laws were enacted by Kentucky, Louisiana, and Ohio. The adoption of non-export provisions in several States reduces the number of States which permit unlimited export of game to three, all in the South. Three States — Kentucky, New Jersey, and Ohio — adopted the license system, by which non-residents are required to secure licenses to hunt, fixing fees of $10 in New Jersey and $25 each in Kentucky and Ohio. Non-resident licenses at rates ranging from $5 to $40 are now required in half the States and Territories and in nearly all the Provinces of Canada. Arkansas and Oregon, however, require licenses only for market hunting, and New York only from residents of States which demand similar licenses from residents of New York. Louisiana and Missouri do not permit non-residents to kill game within the State. Additional restrictions on the sale of game were adopted in South Carolina, and a statute allowing dealers to hold their game under bond during the close season was passed in New York.

The movement toward securing uniform laws for the protection of song, insectivorous, and other non-game birds made substantial progress during 1902. Alaska, Kentucky, and Ohio extended protection to birds other than game, increasing the number of States which now have a practically uniform law of this kind to 19. A similar law was adopted for the Northwest Territories, Canada, and the legislature of Maryland passed a law of like character for Washington County.

New York in 1902 raised the number of its game protectors from 38 to 50, and New Jersey has given its wardens additional powers to make searches and seizures. In Oklahoma the territorial authorities seized several large consignments of game en route to eastern markets contrary to law, and have taken steps to secure a more stringent enforcement of the non-export laws.

Under the Lacey Act numerous seizures were made of game shipped from the West and Southwest, and proceedings were instituted in a number of cases in State and Federal courts. In some of the cases in Iowa and South Dakota convictions were secured with penalties ranging from $150 to $200. The inspection of foreign birds at the port of New York was made more effective, and special inspection service was established in Hawaii and extended in scope so as to prevent the introduction of noxious reptiles into the islands.

Even more important than the enactment of new game laws has been the work of game commissions and voluntary organizations interested in the practical protection of birds and game. In 1902 important changes were made in the game commissions of Ohio and Vermont, and a new territorial warden was appointed in Oklahoma. Several sportsmen's game and fish protective associations were added to the large number already existing, and new Audubon societies were organized in Louisiana, Nebraska, North Carolina, Oklahoma, and Oregon. Thirty-two States now have Audubon societies, which are formed primarily for the protection of birds other than game. The committee of the American Ornithologists' Union on the protection of birds extended its work along the coast, and now maintains supervision of all the breeding colonies of sea birds on the Atlantic coast from Eastport, Me., to Chesapeake Bay, as well as at some points in Florida.

Practically all the State game laws passed by the various State legislatures prohibit the export of game, hunting, or fishing for commercial purposes, and hunting big game with dogs. In a few States the netting of minnows for bait is also prohibited. The killing of song birds is forbidden in most of the States, but this law does not apply to the hawk, owl, crow, blackbird, and English sparrow. Hunting and fishing in the national Yellowstone Park is prohibited.

While the close and open season for hunting and fishing are well defined in all the States, there is no general statement which can cover the question, the seasons and conditions varying so widely. In Alabama, for instance, deer may be shot for four months only (September to January) in Indiana all the time, and in Illinois no deer can be shot until 10 May 1906. All State game laws are peculiarly adapted to local conditions. See AUDUBON SOCIETY; FISHING; HUNTING.

Game Preserves, or **Game Parks,** are large reservations of land, usually including mountain and forest, set aside by the government or

individuals, for the propagation and preservation of game. Game preserves have been well known in Great Britain and on the Continent for upward of five centuries. Henry VIII. established a royal deer park near Hampton Palace in 1526, and the Duke of Sutherland at the present day owns the largest game preserve in the world. Game preservation in the United States first attracted attention just prior to the Civil War and later when the rapidly increasing settlement of the States threatened the extinction of all kinds of wild game.

The United States government took up the question of game preservation almost as soon as the individual, and the establishment of the Yellowstone National Park in the Rocky Mountains, and the Yosemite National Park in California had as much to do with the protection of big game as in the preservation of forests. In these two reservations the government ranges have endeavored to preserve and protect such large game as the buffalo, elk, and moose. In 1902, President Roosevelt, himself a hunter of big game, declared no less than 12 new national forest reserves, which while largely important to forestry, will greatly assist in the protection of big game. These new reserves have a total area of 14,276,476 acres, which makes a grand total of government parks and reservations of 60,162,525 acres. The new reserves added in 1902 were as follows:

	Acres
The San Isabel, Colorado	77,980
The Santa Rita, Arizona	337,300
The Niobrara, Nebraska	123,779
The Dismal River, Nebraska	85,123
The Santa Catalina, Arizona	155,520
The Mount Graham, Arizona	118,600
The Lincoln, New Mexico	500,000
The Chiricahua, Arizona	169,600
The Madison, Montana	736,000
The Little Belt Mountains, Montana	501,000
Alexander Archipelago, Alaska	4,506,240
The Absaroka, Montana	1,311,600

Of private game parks in the United States, the first of record was that of Judge J. D. Caton, of Ottawa, Ill., the author of ‘Deer and Antelope in the United States.’ This he established in 1860, for sport and study, bringing together on his large estate many varieties of game animals native to America. In 1889, Austin Corbin enclosed the largest preserve in the United States, and next to that of the Duke of Sutherland, the largest in the world. It is known as Blue Mountain Forest and is situated near Newport, N. H. It contains over 36,000 acres, and is surrounded by a wire fence, 8 feet high, forming an oblong tract 12 by 5 miles, and which is crossed by a mountain range, the peaks of which are 3,000 feet high. Here are miles of wooded slopes, dense forests, and broad meadows, giving food and shelter to all kinds of game animals, from the buffalo, elk, and moose to the smaller species. The experiment has been most successful, nearly all of the animals thriving and increasing rapidly in numbers. In 1870, F. S. Giles laid out the Grove Park reservation, containing 17,000 acres, and this experiment was followed by Dr. W. Seward Webb with a preserve of 9,000 acres at Nebasane, N. Y., in the Adirondacks, and another preserve at Shelburne, Vt. The Litchfield Park at Tupper Lake, N. Y., in the Adirondacks, was established in 1893, with 9,000 acres, and in 1900 hundreds of herds of large game were roaming the mountain forests within this tract. In the same region the Adirondack Timber Company has a park of over 30,000 acres, well stocked with animals. George W. Vanderbilt at his Carolina estate of Biltmore, has 80,000 acres, 6,000 acres of which are enclosed and well stocked with game. A small army of men are engaged here as keepers. In many of the smaller parks particular attention has been paid to game birds, such as the English pheasant, prairie chicken, and wild turkey. A lover of birds imported large numbers of Japanese pheasants for his preserve in Oregon in 1893, the experiment proving a great success. E. C. Benedict, of Greenwich, Conn., has established extensive fish preserves in Long Island Sound, which are the largest and most successful of their kind in this country. Near Plattsburg, N. Y., Paul Smith owns an immense preserve around St. Regis Lake of 40,000 acres. Large numbers of elk were brought here from the West in 1903. William C. Whitney of New York has been active in stocking the Adirondack region with big game, and in conjunction with Dr. F. E. Kendall, of Saranac Lake, has restocked the forests with elk and deeer. At Delaware Water Gap, Pa., on the New Jersey side of the Delaware River, Barclay Warburton, of Philadelphia, established in 1902 an extensive deer park, which is one of the most successful in that section of the country.

In Canada there are several large game preserves, prominent among which is the Caughnawaga reservation on the Maquacippi River. The Roberval Club, which has a membership of 300, including both American and Canadian, owns a big game preserve containing 500 square miles, located in the Laurentian Mountains. Henri Menier occupies as a game park the whole of Anticosti Island, in the Gulf of St. Lawrence.

Games. Games are an expression of the play instinct, a distinct species or form of play. A study of them includes a definition of games as distinguished from play; and a consideration of games from historical, educational, and recreative viewpoints. While the term play includes games, so that we "play games," it is technically applied to informal play activities, such as playing horse, playing house, and playing in the sand. In such play there are no fixed rules, no formal mode of procedure, and generally no climax to be achieved. The various steps are spontaneous, not predetermined, and are subject to individual caprice. In games, on the contrary, as in blindman's buff, prisoner's base, or football, there are prescribed acts, subject to rules, generally penalties for the infringement of rules, and the action proceeds in a formal evolution until it culminates in a given climax; which generally consists of a victory of skill, speed or strength. This definition applies to games that require considerable bodily activity, such as those mentioned, and to so-called quiet games, as dominoes, cards, jackstraws, chess, checkers and other board games. Our concern in this article is chiefly with active games.

Among the simplest of active games are singing games, in which the action is mainly a repetition of dance movements, or of some dramatic or descriptive motions, as when the farmer sows his seed or London Bridge falls down upon its victim. More strenuous are the games of chase, such as tag, cat and rat, and

Red Rover; or competitive games of skill, strength or speed, illustrated by relay races and athletic contests. Highest of all, both in their organization and their demands upon the varied powers of players, are team games, of which baseball and football are popular examples. Team games are peculiar to the Anglo-Saxon race; nearly all games of the other classes are of very ancient origin and of wide distribution among the races and nations of men. Indeed, the games of children form a distinct branch of anthropology, ethnology and folklore, and throw much light on early customs from which they are descended; for they come trooping out of the past unconsciously bearing the relics of primitive civilizations, of old religious rites and grim superstitions, of marriage and May-time festivals and "battles long ago." "Oats, peas, beans, and barley grows" had its origin in a religious rite intended to increase the fertility of the fields; "London bridge," in the offering of a human sacrifice at the building of a bridge; "Here we go round the mulberry bush" is the survival of a custom, still practised by some of the European peasantry, and known to have existed at least as far back as the early Greeks, of celebrating May day or spring time with the gathering of flowers and marching in procession. This usage prevailed among the American colonists, and from it have come our May basket and May pole customs. Indeed, most of these singing games and many other active parlor games now played by children, such as stage coach, and going to Jerusalem, were used instead of the dance by the young people of the Puritan era. Among the games of religious or superstitious origin tag should be mentioned, which, in its earliest form of iron tag, represented flight from an evil spirit, against whose influence iron was a protection. The little kindergarten game, "I put my right hand in," is very ancient, and with its chorus "Looby loo" gives evidence of having been part of a religious rite to some deity. In time it became a stately court dance, which rank it held a century ago. From the superstitious customs of divination by lot have come the doggerel "counting out" rhymes used by children the world over for choosing the principal players in games. Familiar are the stanzas of this kind beginning "Ena, mena, mina, mo," and "Onery, twoery, tickery, tee." Of similar derivation is the custom of assigning parts by "holders," in which one child holds a pebble in the closed hand, and another guesses which hand contains it. Courtship and marriage customs are perpetuated in "Round and round the village" and "Little Sallie Waters." Still other games, for example, "Uncle John is very sick," come from the ballad days when a versified narrative was sung and acted at the same time;—days when to "sing a dance" and "dance a song" were interchangeable terms.

Athletic games, or competitive trials of individual strength, speed or skill under fixed rules, are probably pre-historic. The mention of them takes one's thought at once to "the glory that was Greece and the grandeur that was Rome." The Greek games have been immortalized in literature and art; prominent examples of which are the Iliad and Odyssey, Pindar's 'Odes of Victory,' and, in sculpture, the discobolus or discus thrower, and the wrestlers. These Greek games were played at four stated festivals, the greatest being the Olympic, which became a national festival about 776 B.C., and recurred every four years at Olympia in Elis. The importance of the Olympic festival in Greek national life may be judged from the fact that time came to be reckoned in Olympiads. The Pythian games were celebrated in the third year of each Olympiad, the Nemean games in the second and fourth years of each Olympiad, and the Isthmian games in the first and third years of each Olympiad. All were held in honor of some god. In Homeric times the events in athletic games were chariot racing, boxing, wrestling, foot racing and javelin throwing. The Olympic contests, which came later, were probably confined at first to foot racing; to this other events were gradually added until the pentathlon came into existence, about the 18th Olympiad, and boxing and chariot racing were added in the 23d Olympiad. The pentathlon consisted of leaping, spear throwing, discus pitching, running and wrestling. It thus called for "all-over" work, thereby preventing inharmonious development by over-specialization. A competing athlete was obliged to enter for all five contests and was considered a victor only upon winning at least three of the five events. The best modern athletic games embody these principles in what are called group contests. For instance, in the pentathlon of the Young Men's Christian Association, the 100-yard dash is equivalent to the Greek foot race; throwing the 12-pound hammer is equivalent to discus throwing, the running high jump to leaping; pole vaulting for height is a substitute for hurling the spear, and the one-mile run for wrestling. The prizes for the Greek games had no intrinsic value and were merely symbols of honor, as wreaths or palm branches. The prestige and indirect advantages accruing to a victor, however, became in time so great that contestants spent all of their time training for the games. The entrance of this professional and commercial spirit led to the decadence of the games. A similar degeneration occurred much more quickly in Rome. In these latter days we have had the dramatic spectacle of the revival of the Greek games as international contests, the first of these occurring in Athens in 1896. The countries represented by the contestants in these international games included: Germany, England, Austria, France, Italy, Switzerland, Sweden, Hungary, Denmark, Greece, Australia, and the United States.

No mention of the Greek games would be adequate that did not include the balanced relation which they held to the intellectual, artistic and ethical interests of the time. The contestants were examples of balanced culture, and the festivals drew together the greatest poets, philosophers, orators, and artists whose achievements were there displayed. The tournaments or jousting bouts of the age of chivalry may be cited as a further example of athletic contests of great popularity in which the concern for physical prowess was blended with higher interests. It is notable that the modern organizations which have made physical training most popular, the German Turnverein, the Young Men's Christian Association, and the colleges, also combine these varied elements.

Ranking higher as games than individual contests, because more complicated in their organization and demands, are team games in which opposing groups contest, each as a unit against the other. Each player on such a team has his assigned part or duties, differing from many of the others, but as an individual he is subordinate to the interests of his team. Games of this class are an expression of the fighting instinct, and undoubtedly are a development from the simpler fighting games played by young boys, such as stealing sticks (Scots and English), and prisoner's base, which in turn are supposed to have originated in border warfare. Between these simpler games and the highly developed team games there exists the same differences of organization as between primitive and modern warfare. The former was merely a series of individual combats, the parts enacted by the various contestants being homogeneous, and, the fight once on, very largely a matter of individual initiative. In modern warfare there is greater differentiation of duties, and the individual is subordinated to the organized whole. The team games most popular in the United States are baseball, football, basket ball, cricket, and hockey. Baseball has been called the national game of the United States, as cricket and Rugby football are distinctive of England, golf of Scotland and hand ball of Ireland. Basket ball bears the unique distinction of being the only game of wide and enduring popularity which was deliberately invented. Dr. James Naismith devised the game about 1892, as a result of studying the principles involved in successful games. Though invented for and played by men, it is the only team game that has become popular with women. Competitive adult games largely in vogue, which depend upon skill, rather than upon a combination of skill and organization, are tennis, golf and croquet.

The anthropological tenet, that in his development the child passes through the stages which the race has gone through before him, finds strong confirmation in children's plays and games. "The work of adults in one age of human history becomes the play of children in another." While the play of civilized children, as of savage, shows imitations of current adult activities, nearly all of the games of civilized children would seem to take their players through the primitive culture epochs. Just what this, or the lack of it, may mean for individual development we cannot say; but it may be inferred from the direct training of power which games provide. The value of this training assumes a clearer position in the light of one of the fundamental concepts underlying the science of education, that of the meaning of the long period of human childhood. Prof. John Fiske pointed out in his 'Outlines of Cosmic Philosophy,' and President Nicholas Murray Butler elaborated in 'The Meaning of Education' the significance of the long interval between birth and maturity in the human species as compared with animals. This significance lies in the importance of adaptation to environment as an element of survival. The animal that lives in a comparatively simple environment, and for which reflex actions are sufficient to maintain life, as the chicken that pecks for food, has but a brief period between birth and maturity. The more complicated environment of the human species, intellectual, industrial, sociological, aesthetic, ethical and spiritual, in which intelligence takes the place of reflex action, calls for a much longer period for adaptation.

The function of education is to assist in this adaptation, and it needs not to be said in an age of the kindergarten that play is one of nature's great means of education, and therefore of adaptation. "Animals play," says Karl Groos, "not because they are young: rather they have a period of youth because they need to play." And the same may be said of children. Physically, mentally, morally, socially, play develops the child, and in that development games have an important and often a unique part. All of the games here passed in review give expression to simple instincts which are basic to strong and effective character and therefore help to develop those instincts. Prof. William James says, "All simple, active games are attempts to gain the excitement yielded by certain primitive instincts, though feigning that the occasions for their exercise are there. They involve imitation, hunting, fighting, rivalry, and acquisitiveness, combined in various ways."

Physical development would obviously result from playing active games. Especially in all running games are strength and endurance of heart, lungs, and related organs cultivated. Neuro-muscular development becomes apparent in agility and skill, from the stumbling child who learns to dodge quickly and skilfully to the expert ball player. Sense organs become more acute. Various powers of the mind are likewise developed and strengthened by the demands made upon them. Sense perceptions gain in rapidity and accuracy, so that a player sees or hears more quickly that which comes in his direction or takes place around him; feels more quickly the touch upon the shoulder that makes him "it." Reactions become quicker and more exact, whether they be the simple reactions of ball catching, or the complicated ones involving reason and judgment, as when one grasps the shifting conditions of a rapid game with many players, and with swift decision adapts his own movements to them. For socionomic training games have peculiar potency; they develop power of co-operation; the sense of, and ability for, social relations, for taking a part in a social whole. Selfishness gives way to generous recognition of ability, and acknowledgment of superior ability, in others; and, highest of all, self is subordinated to the interests of a group. This self-subordination is a distinctive feature of team games, and perhaps does more than anything else to give them high rank in the hierarchy of games. It frequently happens in such games that a player must lose an opportunity to make a brilliant display of his own powers for the sake of a larger advantage to his team. True team play of this character does not appear until adolescence, the games common to an earlier age calling for individual play, or the competitive element, or the homogeneous social characteristics of the folk games. The training of the will is another strong educational feature of games. The timid, hesitating child, who at first shrinks from exposed positions or an aggressive part, gains courage and self-reliance; defeat becomes, instead of a discouragement to all effort, a spur to greater; and the inhibitive

control required to obey rules and regulations, especially under strong excitement, touches another of the well springs of character. So, from the first, clumsy, timid efforts of the little child, to the skilful team work of the college athlete, at once aggressive and self-controlled, games afford a means of development and training for body, mind and character. Were any of these results objects of conscious endeavor on the part of the players, the recreative element of games would be lost. But their unique power lies in the fact of this recreation — this objective interest which holds the attention involuntarily and renders the training incidental, unconscious and natural. Because of this psychological distinction, the expression "gymnastic games," which is frequently heard, is a contradiction in terms and a misnomer. A mistake also is an occasional tendency to discard gymnastic exercise in favor of games, and *vice versa*. While each is an important part of physical training, psychologically and physically there are essential differences between the two forms of exercise. Gymnastics are taken for the purpose of bodily development, and the mind is continually in the unnatural attitude of consciously directing the automatic processes of muscular co-ordination; games are played for the frolic or the victory, without subjective or utilitarian end. This psychological difference is exactly that between work and play. Physically, gymnastic exercise may be more closely adapted to individual powers and needs than the exercise of games; it can afford more vigorous exercise in a brief time to large numbers in limited space; and it is corrective of posture — of faulty neuro-muscular habits. Games, on the other hand, offer a more natural form of exercise, have a larger emotional content, and in their social and psychological training are not approached by gymnastics.

The recreative element in games, the sheer fun and frolic spirit, and the engrossing interest that springs from primitive instincts, cannot be too highly valued as a relief from the pressure which modern civilization brings to bear upon both children and adults. Especially under city conditions should this be fostered. The paucity of childish play and normal youthful sport in cities, owing to lack of space, is not only pitiable, but tragic in view of all that it may mean for the healthful, balanced development and life of the individual. The growth of indoor games as basket ball and indoor baseball, is admirable because making a virtue of necessity; but the movement to provide playgrounds is still better, for gangs of youthful criminals and depredators are found to melt away before them, and the play and games which they foster belong by inherent right to the open sky and the free air. See BASEBALL; BASKET BALL; FOOT-BALL; FOLK-LORE; HOCKEY, ETC.

JESSIE H. BANCROFT,

Gammer Gurton's Needle, a drama by John Still, supposed to have been the first play acted at an English university, is also one of the two or three earliest comedies in our language. In 1575, nine years after it was staged at Christ's College, Cambridge, it made its appearance in print. The plot is very simple. Broad jokes, extravagant language, and situations depending for their fun on the discomfiture of one or another of the actors, gave this play great popularity in its day. Readers of the present time who penetrate behind its quaint and uncouth language will find in it an interesting picture of 16th-century village life.

Gamp, MRS. **Sairey,** in Dickens' 'Martin Chuzzlewit' (1843–4), a stout and elderly professional nurse with a watery eye and a fondness for spirits. She is loquacious and confidential, and continually refers to the opinions of a fabulous being, "my friend Mrs. Harris." Her amorphous umbrella has furnished the name "gamp" for that type of impedimenta.

Gamtoos (găm'tōs) **River,** Cape Colony, South Africa, which rises in the plateau of Great Karoo and empties into the Indian Ocean.

Gam'ut (Italian, *gamma;* French, *gamme*), the name given in the system of Guido d'Arezzo to the entire series of musical tones in the natural order of ascent or descent. The musicians of the 11th century made use, to distinguish a succession of tones of several octaves, of the following scale: *A, B, C, D, E, F, G, a, b, c, d, f, g, aa, bb, cc,* etc. *A* represented the lowest note in their instruments; a lower note having been introduced the Greek gamma (Γ) was taken to represent it in order not to repeat any of the previous signs. The gamma being thus the first note of the scale, its name was taken to represent the whole. The *ut* is the

first word of a Latin hymn formerly used in singing the scale.

Gananoque, gä-nä-nōk', Ontario, Can., a port of entry of Leeds County, 18 miles northeast of Kingston, on the St. Lawrence River, at the point where it flows from Lake Ontario. It is opposite the Thousand Islands, and has long been popular as a summer resort. It has a fine insular public park, and manufactures machinery and farming implements. Pop. (1901) 3,526.

Gándara, gän'dä-rä, Philippines, a pueblo of the island of Samar, situated in the western part of the island on the left bank of the Bachao Bañgahón River. In 1900 it was almost entirely destroyed during an engagement with insurgents; before that it had a large trade. A United States military station and depot for stores is situated eight miles by river from Gándara. Pop. 15,600.

Gando, gän'dō, Africa, a kingdom of the western Sudan, intersected by the Niger, and inhabited chiefly by Fellatahs, with a capital of the same name. It is a most fertile district, the rain being plentiful. Mohammedanism is the prevalent religion. Gando is now comprised partly in British and partly in French territory. Pop. estimated at 5,000,000.

Ganges, gān'jēz, one of the greatest rivers of Asia, and "the sacred river of the Hindus," rises in the Himalaya Mountains, in the province of Garhwal, northern India. It is formed by the junction of two head streams, respectively called the Bhagirathi and the Alaknanda, which unite at Deoprayag, 10 miles below Srinagar, 1,500 feet above the level of the sea. The Bhagirathi which flows from an ice cave in a snow field, 13,800 feet above sea-level, is usually considered the source of the Ganges from its being a sacred stream in Hindu mythology; but the material claims of the Alaknanda are preferable, as it flows farther and brings a larger volume of water to the junction. At Hardwar, about 30 miles below the junction of the head streams, and about 120 miles north-northeast of Delhi, the river is only 1,000 feet above sea-level. Here it enters the great valley-plain of Hindustan, and flows in a southeast by south direction until it discharges itself by numerous mouths into the Bay of Bengal, a distance exclusive of windings of fully 1,100 miles. Its length, with deviations, is calculated at about 1,500 miles. During its course it is joined by a number of large rivers, the principal of which are the Jumna and Son, joining on the right bank; the Ramganga, Gumti, Gogra, Gandak, and Kusi, on the left bank. Some of the principal cities on the Ganges and its branches, descending the stream, are Cawnpore, Allahabad, Benares, Patna, Behar, Murshidabad, and Calcutta. The Ganges is navigable for boats of large size nearly 1,300 miles from its mouths. It is a great feeder of irrigation and navigation canals. (See GANGES CANAL.) Its utmost breadth is about three miles, with a maximum depth of about 30 feet in the dry season, and 60 feet in the wet. Its descent is computed at four inches per mile; its current in the dry season is less than three miles an hour; in the wet season five or six. The quantity of water discharged into the ocean is estimated at 500,000 cubic feet per second during the flood season, and 100,000 during the remaining eight months of the year. Its current brings down a great quantity of mud, which in the course of ages has contributed to form the wide delta which belongs to it in common with the Brahmaputra. The delta, intersected by numerous branches, extends from east to west from 80 to 200 miles, and commences about 200 miles, or 300 by the course of the river, from the sea. A part of it is an uninhabited region called the Sundarbans, overgrown by jungle, infested with tigers and crocodiles. The westernmost deltaic branch of the Ganges called the Hugli, is the only branch commonly navigated by ships; and vessels drawing 26 feet are safely piloted up to Calcutta; the construction of embankments, and continuous dredging, are necessary to keep a clear channel. The Ganges, as the Padna, continues eastward until it joins the Jamuna, the main branch of the Brahmaputra, which flows through the estuary of the Megna, the deltaic boundary on the east, into the Bay of Bengal. The periodical inundation of the Ganges commences about the end of April with the tropical rains. It rises gradually till it attains, near the commencement of the delta, a height of 32 feet above its ordinary level. By the end of July, the flat country of Bengal is overflowed to the extent of 100 miles in breadth, leaving visible little but tops of trees and villages, which are often built on artificial mounds above flood mark. After the middle of August the water begins to recede, and decreases till the period of the next inundation.

That part of the Ganges which lies between Gangotri, the first temple and pilgrim resort on its banks, 10 miles from its source, and Saugor Island, below Calcutta, is held particularly sacred. Wherever the river runs from south to north contrary to its usual direction, and at the junction of its affluents, it acquires a more peculiar sanctity. Its junction with the Jumna at Allahabad (q.v.) forms the most venerated place of Hindu ablution. The Hindus believe that this river rises immediately from the feet of Brahma, and that it possesses great and miraculous cleansing powers on account of its divine origin. There is a scientific basis for this universal faith among Hindus, repeated and careful experiments showing that the river possesses extraordinary but hitherto inexplicable antiseptic qualities.

It is an imperative duty of the Hindus to bathe in the Ganges, or at least to wash themselves with its waters, and to distribute alms, on certain days. Whoever dies on its banks, and drinks of its waters before his death, is thought to be exempted from the necessity of returning into this world and commencing a new life. Whenever, therefore, a sick person has been given over by the physicians, his relations hasten to carry him to the bank of the Ganges, in order that he may drink of the holy water, or be immersed in the river. Such as live too far from the river to admit of this, always preserve some of the precious water, as a sacred treasure, in a copper vessel, that it may be given them in the hour of death. This water is, therefore, a considerable article of commerce in India. It is also customary, after the dead have been burned, to preserve the remains of the bones and the ashes until an opportunity offers of throwing them into the Ganges.

The name Ganges is derived from *gam*, a Hindu verb signifying "to go." In Hindu mythology the river is personified as the goddess Gangā.

Ganges Canal, The, in India, an important irrigation work and navigable channel, the older portion called the Upper Ganges canal, opened in 1854, and extending, on the right of the Ganges (q.v.) from Hardwar to Cawnpore and Etawah, with a main canal 440 miles long, navigable throughout; and with 2,634 miles of distributaries. The Cawnpore and Etawah terminal lines are now absorbed in the Lower Ganges canal, commenced in 1873, and which continues in its main branch for 260 miles to Allahabad, drawing its supply from the river at Narora, in the Aligarh district. The weir and headworks at Narora include a solid wall, 3,800 feet long, with 42 weir sluices, founded on huge square blocks.

Gan'glion, connective tissue membranes enclosing small amounts of clear synovial fluids. They are usually found where tendons or muscles glide over bony parts, or where the skin, muscles, or fascia are subjected to pressure or to friction. The number, size, and location of these structures are subject to much individual variation. One of the commonest is found on the back of the hand, at the wrist, particularly in people who stretch their fingers widely, as piano players, or as librarians who handle many books, grasping several at a time. In this form is a firm and painless swelling, liable to be caused by any excessive exercise of the wrist, as in playing tennis, golf, etc. This swelling gives the impression that there is fluid beneath the skin, and grandmother's advice to break it with the family Bible or the dictionary is often followed, sometimes with serious results. This forceful method of reduction is foolish, as most of the swellings disappear with rest and the application of heat. If they persist, a surgeon should be consulted. Another very persistent variety of this trouble is found in the knee — causing housemaid's knee, or miner's knee. Obviously the breaking of these tumors by force is out of the question. There are many places in the body in which similar collections of fluid may accumulate, but these rarely cause much inconvenience unless they become infected through some knock or cut. In this event prompt surgical treatment is advisable, and aseptic surgery should be insisted on. A careless and unclean surgeon may render a limb useless.

Gangotri, gän-gō'trē, a square temple, about 20 feet high, erected on the right bank of the Ganges (q.v.), which here forms a small bay, about 10,319 feet above the level of the sea. This spot is regarded by pilgrims as the source of the holy stream, here called the Bhagirathi, which, however, rises 8 miles higher up. The water here is peculiarly sacred, but few pilgrims come so far, and the only dwelling-house in the locality is occupied by the officiating Brahmins, by whom flasks of the holy element are sealed for conveyance to the plains.

Gangrene, găn'grēn, the term applied to death of soft tissue in masses large enough to be seen. There are two forms, differing in causation, appearance, and progress. Dry or senile gangrene results from the gradual occlusion of arteries, the venous return being unimpaired. For weeks or months the toes and feet, the parts most frequently affected, may feel cold or numb, or be actually painful, then gradually the skin becomes dry, then purple and black. The spread is usually very slow. It is particularly a disease of old age, due to the tendency at that period of life toward thickening and stiffening of the arterial walls.

Moist gangrene results from sudden stoppage of the arteries, obstruction of veins, mechanical destruction of the tissues, or from specific infection by germs. This form shows a soft, boggy, bluish mass covered with blisters and emitting the odor of putrefaction. In both forms of gangrene there may be a zone of inflammation between the dead and the living tissue, called the line of demarcation.

Hospital gangrene was formerly very prevalent in military hospitals; a wound becoming infected would quickly change to a gray slough, which in a few hours might involve the entire limb unless prompt removal of the tissue was undertaken. Aseptic surgery has made this fatal disease a thing of the past.

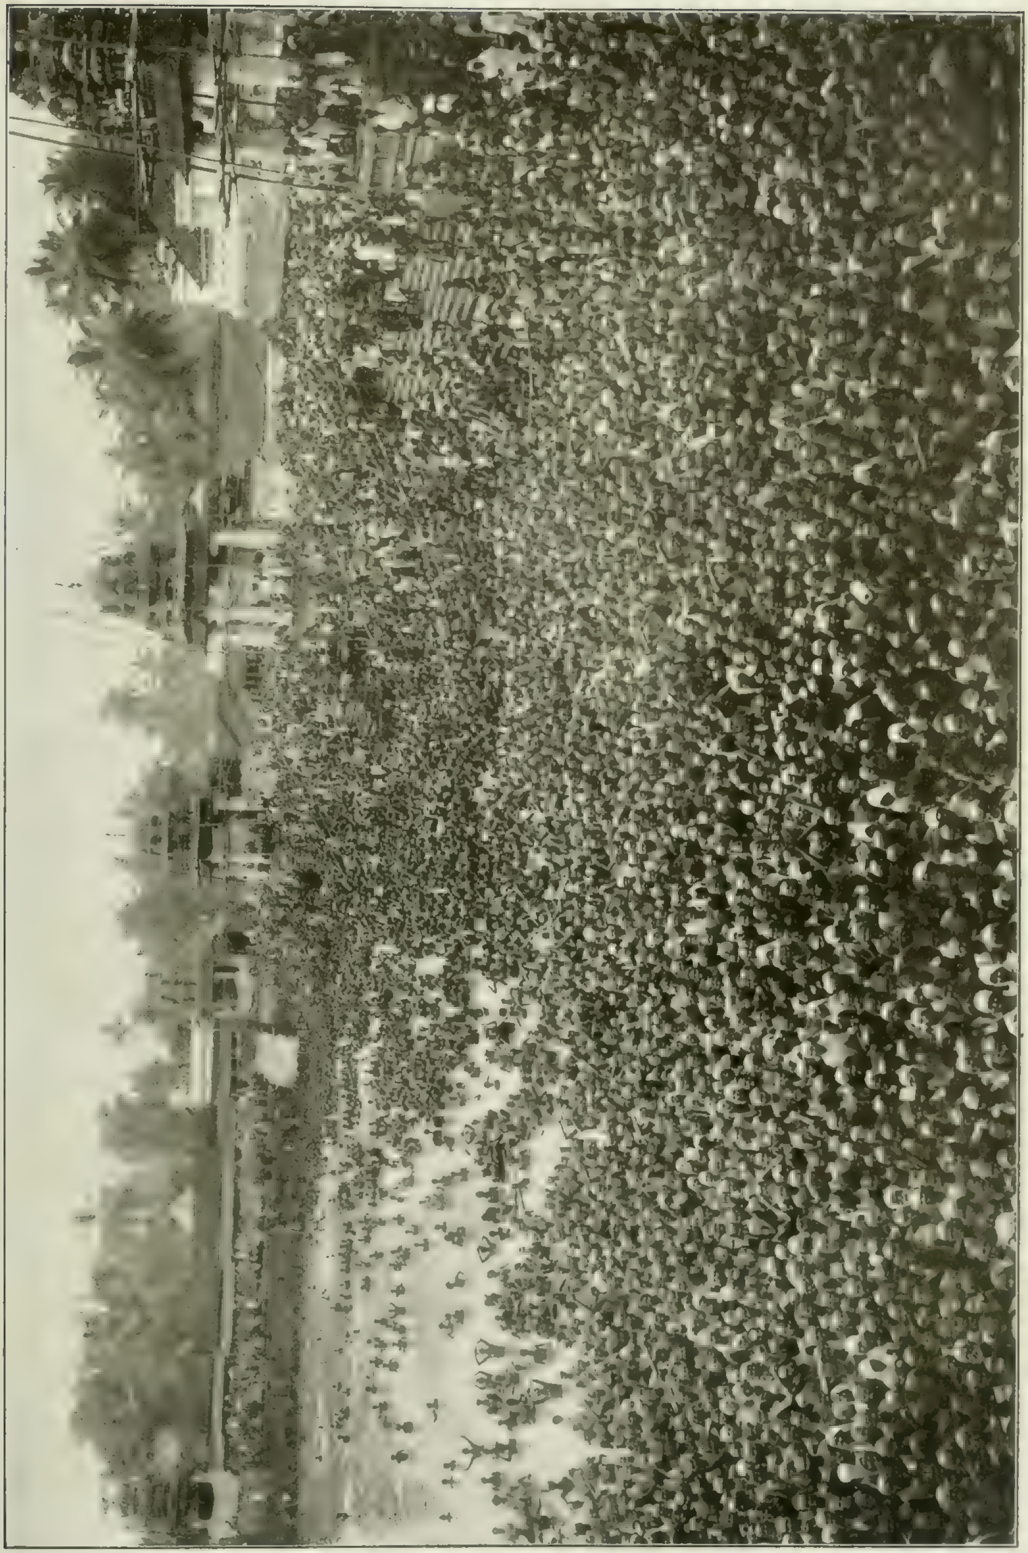
Spreading gangrene is due to infection by a specific germ, the bacillus of malignant œdema, so called from the fact that it generates a gas that puffs up the tissue affected. The spread is rapid, and life is sometimes saved by amputation far above the wound. The treatment of gangrene is usually a matter of amputation, well beyond the affected part. Careful aseptic dressing is imperative, particularly where the condition of the patient is apt to contra-indicate radical cure.

Gangue, găng (Ger. *Gang*, a vein), the matrix or veinstone of ores. These are always included in some stony matter, which forms the principal portion of the veins or beds which are worked for the sake of their metalliferous contents. Quartz is the most common veinstone, and has been called the mother of ores. Calcareous spar is also a frequent predominant material of veins. Sulphate of barytes or heavy spar, and fluor spar, are also often found as gangues.

Gan'ister, a name originally given in England to a particular clay high in silica, used in the manufacture of fire-brick. In this country the term is used more loosely and includes non-plastic rocks that are not clays at all but approach sandstones in character. Ganister may, therefore, be defined as highly silicious material used in the manufacture of fire-brick, more particularly what are known as silica-brick, for lining blast-furnaces, Bessemer converters, etc. The manufacture of such brick is an important industry in Western Pennsylvania. See CLAY.

Gannal, gä-näl, **Jean Nicolas,** French chemist: b. Saarlouis, Prussia, 28 July 1791; d. Paris January 1852. He is noted for his invention of the method of embalming by injection.

Gannets, large sea-birds constituting the family *Sulidæ*, of the order *Steganopodes*, characterized by having all the toes connected by webs, the absence of external nostrils and a very short tongue. They are closely related to the pelicans and cormorants, have large powerful bills and feed upon fish, frequenting the sea-coasts of various parts of the world. The common gannet



BATHING IN THE GANGES.

(*Sula bassana*), to which the name properly refers, is restricted in the breeding season to a few rocky islets on the coast of the British Isles and Iceland — notably the St. Kilda group, and to Bird Rock in the Gulf of St. Lawrence; and their numbers have been much diminished by the fishermen who gather their eggs for food. They nest in colonies among the crevices and ledges of the rocks, and each bird lays a single large chalky white egg. When the young are on the wing they all leave together and scatter widely in search of food, extending their range on our coasts as far as the Gulf of Mexico. In the southern hemisphere are two closely related gannets. *S. serrator* of Australia and *S. capensis* of South Africa. Eight other somewhat smaller species, called «boobies» (q.v.), breed on various tropical islands. The common gannet is pure white with black outer wing-feathers and a buffy suffusion on the head. The young are mottled grayish brown. The other species are similar, many of them with red and blue coloring on the bare skin of the throat and around the eye.

Gan'nett, Ezra Stiles, American Unitarian clergyman: b. Cambridge, Mass., 4 May 1801; d. near Boston 25 June 1871. He was graduated from Harvard in 1820, in 1824 became assistant to W. E. Channing at the Federal Street Church, Boston, and later succeeded to the pastorate. In the Unitarian controversies of 1825–35 he took a prominent though conservative part. He was the first secretary of the American Unitarian Association, its president 1847–51, and president of the Benevolent Fraternity of Churches 1857-62. He was also founder and editor of the 'Scriptural Interpreter,' and an editor of the 'Christian Examiner,' and the 'Monthly Miscellany of Religion and Letters.'

Gannett, Henry, American geographer: b. Bath, Maine, 24 Aug. 1846. He was graduated at the Lawrence Scientific School in 1869; became geographer of the United States Geological Survey in 1882; was geographer of the 10th, 11th, and 12th censuses, and of those taken by the war department in Cuba and Porto Rico in 1899. His publications include: 'Manual of Topographic Surveying'; 'Statistical Atlases 10th and 11th Censuses'; 'Dictionary of Altitudes'; 'Commercial Geography'; etc.

Gannett, William Channing, American Unitarian clergyman: b. Boston, Mass., 1840. He is a son of E. S. Gannett (q.v.). He has held Unitarian pastorates at St. Paul, Minn., and other cities, and has been for some years pastor at Rochester, N. Y. He is the author of: 'A Year of Miracle'; 'Memoir of Ezra Stiles Gannett'; 'The Thought of God in Hymns and Poems' (with F. L. Hosmer).

Ganodonta, a group of primitive mammals regarded as ancestral to the edentates, whose remains are found in the lowest Eocene formations of the western United States. These remains are not numerous nor complete, but plainly exhibit a progressive relationship toward modern Edentata (q.v.). The earliest known is *Hemiganus,* from the Puerco beds of New Mexico, which was as big as a medium-sized dog. A later genus of similar size is *Psittacotherium;* and a still later (Lower and Middle Eocene) is *Stylinodon.* In reviewing the series, says Beddard, we see a gradual diminution of the incisors, a gradual loss of enamel on the teeth generally, and the production of hypsilodont teeth growing from persistent pulps, all of which are features of the later edentates. The progression is gradual, but the forms seem to be a continuous series culminating in the ground-sloths. See PALÆONTOLOGY.

Gan'oid Fishes, an order of fishes founded by Agassiz on the character of the scales of certain fossil fishes, which are bony and lustrous, now regarded as a group-name for a rather heterogeneous series of low and chiefly extinct teleost or «true» fishes. (See ICHTHYOLOGY.) The ganoids were most numerous in Palæozoic and early Mesozoic times, and few and diverse are the surviving forms, which include the paddle-fishes and sturgeons, the gar-pikes, the mud-fishes of African rivers and a few others, all elsewhere described. In this group fall some of the most famous fossil fishes of palæontology, described by Hugh Miller in his 'Old Red Sandstone' and otherwise introduced long ago to the public. The *Pteraspis* and *Cephalaspis* of the Upper Silurian and Lower Old Red Sandstone strata had the head covered with a bony shield, which in form somewhat resembled the carapace of some crustaceans; the body of *Cephalaspis* had bony scales. The berry-bone (*Coccosteus*), the seraphim (*Pterichthys*), and the *Asterolepis* also had a bony shield, the flexible trunk having scales in *Pterichthys,* being naked in *Coccosteus.* The anterior limbs, or pectoral fins, of *Pterichthys* were long, covered with closely fitted plates, and had a complex joint connecting them with the thorax. The garpikes of the American lake region, are the modern representatives of the *Lepidotus, Æchmodus,* etc., of Mesozoic strata, and of the Carboniferous *Palæoniscus. Polypterus,* the type of this group, is confined to the Nile, and a few other African rivers. The group is most abundant in the Palæozoic strata, *Dipterus, Osteolepis, Holoptychius, Phaneropleuron,* being Old Red Sandstone genera; *Rhizodus, Megalichthys* with rhomboidal scales, *Strepsodus* with cycloid scales, Carboniferous. The cœlacanths range from the Carboniferous to the Chalk formations, and are the only members of the order in which the tail is homocercal.

Gansevoort, găns'voort, **Peter,** American officer: b. Albany 17 July 1749; d. 2 July 1812. In 1775 he joined the army which under Montgomery invaded Canada, and in 1776 he was appointed to the command of Fort George. In 1777 he was placed in command of Fort Stanwix, which he gallantly defended against a vigorous siege of 20 days by British and Indians under St. Leger, and received the thanks of Congress for having thereby prevented the co-operation of that general with Burgoyne, and contributed to the defeat of the latter. In 1781 the State of New York raised him to the rank of brigadier-general, which he held till the termination of the war. He afterward filled various important offices under the Federal government. He was successively commissioner of Indian affairs, commissioner for fortifying the frontiers, and military agent. In 1809 he was appointed brigadier-general in the United States army.

Gan'ymede (Gk. Γανυμήδης; Lat. *Ganymedes*), in Greek mythology the son of Tros and of Callirrhoë, a daughter of the Scamander. Zeus sent his eagle from heaven, which carried

him off from Mount Ida to the seat of the gods, where he discharged the office of cup-bearer to the immortals, Hebe having rendered herself unworthy of this office. This fiction has afforded, both to poets and artists, an inexhaustible supply of subjects. Numerous paintings, statues, cameos, and intaglios, masterpieces of ancient art, have descended to us, upon which this youth, scarcely past the years of boyhood, is represented as of great beauty. The representations of Ganymede are to be recognized by the Phrygian cap and the eagle, which is either standing beside him or carrying him in its talons to Olympus.

Gapán, gä-pän′, Philippines, a pueblo of the province of Nueva Ecija, Luzon, situated four miles east of San Isidro, the capital. It is at the junction of several roads, and is the largest town in the province. Pop. 20,200.

Gaper, ga′- or gā′per, a name given to many animals who have great mouths, or in some other way suggest gaping. Thus it is one of the British names for the European soft clam (*Mya truncata*) in reference to the wide separation of the shells, as is characteristic of deeply burrowing bivalves; and it is applied to relatives on the Pacific coast of the United States. Among birds, the broadmouths (q.v.) are called gapers; and among fishes some of the sea-bass, which open their mouths in dying to the widest extent.

Gapes, a disease of young poultry, caused by a parasitic nematode worm in the throat. See POULTRY, DISEASES OF.

Gar, Garfish, or **Gar-pike**, one of two sorts of fish, both long and slender, with a prolonged spear-like snout filled with teeth, and hence bearing such local names as "bill-fish," "needle-fish," "bony-pike," etc.; and "green-bone," because of the greenish tinge on the bones. The group originally called "gar" was that of the family *Belonidæ* (or *Esocidæ*), allied to the sauries and flying-fish, the type of which is the common European *Belone belone*. This is a swift, voracious fish which darts along the surface picking up little fishes, and especially playing havoc in shoals of young mackerel. It is usually about two feet in length, is often brought to the London market, and forms a wholesome dish, in flavor somewhat like mackerel. The young forms have at first jaws of a normal size, but in growth the lower outstrips the upper. Very similar, but larger, are the "silver" gars, "agujas," or "needle-fish" of American tropical waters, which offer good sport by their speed and strength, but are hated by practical fishermen whose nets they frequently destroy or damage by their effort to get at imprisoned prey. There are several species, all of the genus *Tylosurus*.

Both these kinds, as well as their Oriental representatives, are often called "gar-pikes" from their pike-like form and voracity; but in the United States this term is suitably reserved for a very different kind of gar, not known in the Old World, and a relic of the ganoid tribe prevalent in the palæozoic seas. This gar-pike represents the family *Lepidosteidæ* (see ICHTHYOLOGY), and has a long almost cylindrical body encased in an armor of white, bony, enameled rhomboid plates, which are imbricated in oblique rows running downward and backward. The jaws are long, narrow, and furnished with sharp teeth, each of which fits into a depression in the opposite jaw; and are covered with a granulated shagreen-like integument. They have the air-bladder subdivided and used in respiration; no spiracle; strong fins; a heterocercal tail; swim well, and prey upon small fishes. Their own flesh is not edible and they interfere with fishing, and therefore are destroyed freely. They inhabit the rivers and lakes of North America, where the commonest species is the long-nosed gar (*Lepidosteus osseus*). Another, more southerly, is the short-nosed gar (*L. platystomus*); and a great and powerful subtropical species (*L. tristœchus*), reaching 8 or 10 feet in length, and called "manjuari" in the West Indies, is known as "alligator-gar" in the lower Mississippi district. Another species occurs on the west coast of Central America; and another in the rivers of China.

All these gar-pikes frequent shallow, reedy, or grassy places, basking in the sun like the pike, and devouring living prey with great voracity. The manner of seizing prey differs from that usually observed in fishes, and resembles that of reptiles; instead of taking their food at once with open mouth and swallowing it immediately, they approach it slily and sideways, and then, suddenly seizing the fish or other animal, hold it until by a series of movements it is placed in a proper position for being swallowed, in the manner of alligators and lizards; the ball of food is also seen to distend the body as it passes downward, as in snakes.

Gar-pike. See GAR.

Garabit, gä-rä-bē, France, in the department of Lozère, is a picturesque locality on the railway from Marvejols to Neussargues, where the line spans a gorge of the Truyère River, about 10 miles south of Saint Flour. The viaduct planned by M. Eiffel is 1,852½ feet long, and is built partly of girders and partly of masonry. Where it crosses the river at a height of 401 feet, it is supported by an arch, with a span of 541 feet 4 inches. Consult: Eiffel, 'Le Viaduc de Garabit' (1889).

Garancine, găr′an-sĭn, is prepared from the ground root of *Rubia tinctorum* or madder (in French *garance*) by washing it with 8 or 10 times its weight of water acidulated with sulphuric acid, 1 part of acid being used for 100 parts of powder. After digesting for 7 or 8 hours the fluid is run off, and the paste is boiled for 2 or 3 hours by steam with more acid, and then the mass is thrown into cold water contained in a large trough with a perforated bottom covered with cloth to act as a filter. Here it is washed till all the acid is got rid of, and the paste is afterward pressed, dried, and ground to fine powder. It is used for dyeing, and has the advantage over madder (q.v.) of containing a large proportion of coloring matter. It is preferable to madder for mixing with other dyestuffs to produce chocolate and some other shades.

Garay, Juan de, hoo-än′ dā gä-rī′, Spanish soldier: b. Badajoz 1541; d. South America 1584. About 1565 he went to South America, where he became secretary to the governor of Paraguay, was sent on a voyage up the Paraná, discovered a vast territory, and founded near the river the town of Santa Fé de Vera Cruz. He

defeated the Charruas Indians not far from the Uruguay, received the commission of lieutenant-general, and was appointed (1576) governor of Asuncion. In 1580 he re-founded the city of Buenos Ayres on its previous site, and subsequently did much to improve the condition of neighboring native tribes. Having landed in an unfamiliar region on a journey up the Paraná to Asuncion, he was there killed by hostiles.

Garbage is kitchen refuse and table waste, offal, or discarded material from the preparation and use of human food. Assembled, it is an ever-varying mixture of animal and vegetable food waste, the nitrogenous or proteids being largely in excess of the non-nitrogenous properties. Garbage decomposes rapidly in the open air and becomes offensive, especially in warm weather. When thrown upon the ground and allowed to decompose, or when used as a fertilizer in a raw state, it may contaminate sources of water supply, and thus become a menace to public health. In country districts and in most towns and small cities it is used as food for domestic animals, and when fresh no more proper disposition of it can be made. When the material is allowed to become partially decomposed before feeding, and where caustic solutions are used for the cleansing of cooking utensils, etc., the mortality caused thereby, particularly among hogs, is so serious as to preclude its use. American cities produce from one half pound to one pound per day for each person. European cities produce less than one half of this amount for each person. Analysis of American city garbage shows moisture 70 per cent to 80 per cent; grease, 2 per cent to 3 per cent; and solids, principally wood fibre, 18 per cent to 28 per cent. Garbage from European cities contains more of solids and less of moisture and grease.

Compared with the garbage of New York city, British garbage contains about 25 per cent and German about 50 per cent less water. Practically, France has no garbage.

No other problem so far encountered has so troubled city officials and boards of health as the disposal of garbage. The thoughtless citizen throws it in the street, or leaves it in his back yard until his neighbors rebel, or he burns it in his range or furnace and has more trouble with his neighbors. He puts it with ashes and other refuse and it is dumped on a vacant lot, or a depression in the ground is filled with it, and injunction proceedings are brought by near-by residents; protests and complaints of every description are made to councilmen, heads of departments, and boards of health. Newspapers take it up, and everyone who can possibly be held accountable is abused. The first attempts at collection and disposal are crude and imperfect. All kinds of household wastes are put together in boxes or barrels and teams are hired to cart it away. In some cases the city owns the horses and wagons required for the work. This lasts until there is no longer a dumping place within hauling distance. In a few instances it has been taken to sea in scows and dumped in deep water. This is found objectionable, as the lighter portions float to shore. Total destruction of the material is the next resort. Inventors and promoters take advantage of the situation, and it is proposed to burn or utilize the material at huge profit. Corporations are formed, stock is sold, and plants are built for final disposal. Then there are indignation meetings and injunction proceedings. No one wants a garbage-disposal plant near his property. Should it be completed and started, it is generally closed within a year, either by injunction or owing to the lack of funds for its operation. The country is strewn with such wrecks. From one to a half dozen can be found in almost every city. Many are so utterly worthless in practice as to approach very nearly to the ridiculous. Others are admirable in design and construction, but fail on account of insufficient returns or excessive cost of operation. Much has been learned, however, through these failures.

It has been found that when garbage is mixed with ashes, paper, and other household waste, final disposal is rendered very difficult, the mass being unfit for filling, fuel, or fertilizer. Leading American cities separate household waste into three parts, namely, "food waste," "combustible waste," and "non-combustible waste." By this means final disposal is more readily effected, each class of waste having properties of commercial value when kept separate from the others. Most European cities do not attempt a separation, excepting it be at the plant where final disposal is effected. In some cases the whole mass is passed through what are termed "destructors," burning the unconsumed carbon found in the ashes, and the combustible portions of other household waste. This system of final disposal has not been found satisfactory in American cities, and has been equally unsatisfactory in some European cities, particularly on the Continent, where, as in America, it is found that much additional fuel is required in order to maintain a proper temperature in the furnaces. Many of them have, therefore, been abandoned altogether, and attention has been turned to some form of utilization as being more reliable and less expensive.

Engineers have struggled manfully with the problem, and have been ably seconded by men of means and energy. It would scarcely be possible to name in this connection all those who have contributed to the development of principles, systems, and apparatus which go far toward the practical solution of this difficult problem. Much impetus was given to effective practical development of the principle of utilization by the determined efforts of the late Col. Geo. E. Waring, New York's indomitable commissioner of streets. After a most exhaustive investigation of the whole subject, and a thorough inspection and test of every system of disposal then in existence, both in Europe and America, Col. Waring became thoroughly convinced that utilization was right in principle and practice, and proceeded at once to have the garbage of the city of New York disposed of in this manner.

Prior to this time there were successful utilization plants in Philadelphia, Pa., St. Louis, Mo., and Detroit, Mich. The system adopted by Col. Waring, and which is now in use in many of the principal cities of the United States, is first, thorough sterilization by subjecting the material to the action of live steam in enclosed vessels, condensing all vapors and passing insoluble gas through flame. By this treatment the structure of the material is broken

down,— even bones are disintegrated,— the liquids carrying the oils and greases being separated from the solids by mechanical means. The further preparation of the ingredients, by which they are put in commercial form or finally disposed of, varies greatly in the different plants. In some cases the liquids are evaporated, in others they are allowed to run into sewers or water courses. In a number of the plants the solid portions are used for fuel; in others they are acidulated or dried and prepared as a base for commercial fertilizers. The greases are sometimes extracted by the use of a solvent, and reclaimed by evaporation, the solvent vapors being condensed and also reclaimed to be used again. The principles involved are not new, having been applied for many years to the treatment of slaughter-house waste. In its application, however, to the greater subject of garbage disposal, much new apparatus has been invented, and the plants have been equipped to handle very promptly a vast amount of the material; the plant which disposes of the entire garbage of the Greater New York having a daily capacity of more than 2,000 tons, and the plants located in Philadelphia, Pa., Boston, Mass., Newark, N. J., Baltimore, Md., Washington, D. C., Detroit, Mich., St. Louis, Mo., Cleveland, O., and in some of the smaller cities, are of sufficient capacity to dispose of all the garbage produced in the respective cities within 12 hours of delivery at the plant. It is this prompt and effective disposal that has rendered the utilization systems so popular in the large American cities. The entire work of collection and disposal is, in most cases, done by contract. The plants are owned by contractors, the cities in some cases collecting the garbage and delivering it upon the contractors' cars or boats for transportation to the place of final disposal. The contractors have expended vast amounts of money in perfecting the systems, and certain features, processes, etc., are kept secret. As they are private enterprises, no statement can be made as to returns from the sale of the products, but it is known that reasonable dividends are paid, and that the contracting companies are in a sound condition financially, while the citizen who notes carefully the service rendered is well satisfied with the results.

The state of the art as to final disposal would seem to preclude the utilization systems in cities having a population of less than 50,000, excepting where a combination plant can be used, thus disposing at one plant of all garbage, dead animals, slaughter-house waste, butchers' scrap, etc. Where this cannot be effected, it has been found that burning is the only safe and effectual means of disposal.

Many of the failures, both in incineration and utilization, are due to the improper location of plants. While it should be perfectly clear to everyone that such plants should be so located as to cause the least possible property loss or inconvenience to the people, yet it should be recognized that every city must have a place for final disposal of its waste, and, once properly located, it must be recognized as such. Though plants for final disposal, when properly designed and operated, have not proved a nuisance to near-by residents, nor a menace to public health, yet the assembling at one point of the material is objectionable and should be restricted to a section for such purposes. See Wastes, City, Disposal of.

Much has been written on the subject by both European and American engineers, principally in the form of papers read before some of the engineering societies, and published in engineering journals. Valuable information can be obtained from the files of such journals. Very little of such material, however, has been put in book form. In a small volume published in 1897, entitled, 'Street Cleaning and Its Effects,' by Col. Geo. E. Waring, interesting and valuable data is assembled, a portion of which bears directly on this subject, and in an English publication entitled 'The Economic Disposal of Towns' Refuse,' W. Francis Goodrich gives a very good description of European and American burning methods, with illustrations, plans, and tables well arranged. His data on the subject of utilization is, however, inaccurate and misleading and does not correctly set forth the true state of the art at the present time. A most comprehensive treatise on the subject is 'The Wastes of a Great City' by John McGaw Woodbury, commissioner of street cleaning, New York, in Vol. XXIV., p. 387, 'Scribner's Magazine' (1903).

Charles Edgerton,
President Sanitary Product Company.

Garborg, gär'bôrg, **Anne,** Norwegian novelist: b. island of Time, Jæderen, 25 Jan. 1851. He was educated at Christiania, published anonymously in 1873 his essay, 'Ibsen's "Emperor or Galilean,"' in 1877 founded the 'Fedraheimen,' a liberal journal which he edited until 1882, and in this as well as 'Den syttende Maj,' another periodical, urged the adoption of a national language for Norway. On this subject he wrote also: 'The New Norwegian Language and the National Movement' (1887). His best-known work was done in his stories, originally written in the popular tongue and largely rendered into Swedish and Danish. They are of the realistic vein so common to Scandinavian writers, and include: 'A Freethinker' (serially in 'Fedraheimen' (1878); 'Men' (1886); 'Weary Souls' (1891); 'Fred' (1893).

Garção, Pedro Antonio Correa, pā'drō äntō'nē-ō kōr-rā'ä gär-säṅ', Portuguese poet: **b.** Lisbon 29 April 1724; d. there 10 Nov. 1772. As a lyric poet he stands very high; while his satires, odes, and epistles,— upon the models of Horace,— are dainty and spiritual. He also wrote successful dramas. The Portuguese esteem him for the perfection with which he employed their language in his works. The 'Hymn to Dido' is one of his most popular productions. He was arrested for a personal satire, and died in prison after a long captivity.

Garcia, Diogo, dē-ō'gō gär-sē'ä, Portuguese navigator: b. Lisbon 1471; d. Madrid 1529. In 1526 he sailed with three vessels from Cape Finisterre for South America, in the employ of the company established at La Coruña for the spice trade. He explored the Uruguay (1827), and the Paraná to 27° S., defeated the Indians who had besieged Sebastian Cabot on the latter river, and in 1528 left for Spain. About 1532 he is said to have made a voyage to the East Indies. His account of his Brazilian ex-

plorations appeared in Vol. XV. of the 'Revista do instituto histórico é geográfico do Brasil.'

Garcia, gär-thē'ä, **Manuel del Popolo Vicente,** Spanish vocalist and composer: b. Seville, Spain, 22 Jan. 1775; d. Paris 10 June 1832. After acquiring a considerable reputation as a tenor singer in Cadiz and Madrid, in 1808 he obtained great success at the Italian opera in Paris, and afterward proceeded to Italy, where he was received with equal favor. From 1816 to 1824 he was constantly engaged as a singer, either in Paris or London. In 1825, with a select operatic company, composed in part of members of his own family, he crossed the Atlantic and visited New York and Mexico. On the road between Mexico and Vera Cruz he was robbed of all his money; and after his return to Paris was compelled to open a class for singing, as his voice had become greatly impaired by age and fatigue. Many of Garcia's pupils reached a high degree of excellence, but none equaled his eldest daughter Maria, afterward Madame Malibran (q.v.). He was less successful as a composer, though several of his works, such as 'The Caliph of Bagdad,' were much admired.

Garcia, gär-thē'ä, **Manuel,** Spanish professor of singing in England: b. Madrid, Spain, 17 March 1805. He was a son of the preceding. He invented the laryngoscope, and published: 'Memoire sur la voix humaine' (1840); 'Trâite de la Chant' (1841); 'Hints on Singing'; etc.

Garcia y Iniguez, gär-se' ä ē-nē'gĕs, **Calixto,** Cuban patriot: b. Holguin, Cuba, 14 Oct. 1836; d. Washington, D. C., 11 Dec. 1898. In 1868, with Donato del Marmol and Carlos Manuel Cespedes, he organized the revolution known as the "Ten Years' War." In the early part of the struggle he won the battle of Santa Maria and recaptured Jiguani. In recognition of his services Garcia was appointed brigadier-general under Gomez (q.v.), and subsequently succeeded that officer as commander-in-chief of the Cuban army. In 1873 he was captured and carried as a prisoner to Spain. In 1879 he returned to Cuba to start "The Little War," but was again captured and kept in Spain under police surveillance for 15 years. In 1895 he escaped and came to New York, where he fitted out a filibustering expedition, which failed to reach Cuba on account of the wreck of the vessel. Later he was successful in landing in Cuba with arms and supplies. He was given the command of the forces in Camaguey and Oriente, where he held almost complete possession, and in 1898 gave valuable aid to the American forces at the capture of Santiago. At the close of the Spanish-American war he was made chief of the commission to discuss with President McKinley the future of Cuba.

Garcia Moreno, gär-sē'ä mō-rā'nō, **Gabriel,** Ecuadorean politician: b. Guayaquil, Ecuador, 1821; d. Quito 6 Aug. 1875. He was educated at Quito and in Europe, became professor of chemistry in the University of Quito, and in 1857 its rector. In 1859, upon the overthrow of the Roble's government, he was chosen a member of the provisional government, and in 1861 president for a term of four years. He declared himself dictator in 1864, subsequently relinquished the title and office, though he maintained virtual control of affairs, in 1869 led a revolution, and became again dictator, and in 1875 was elected president for a six-years' term. Before his inauguration he was fatally wounded by assassins.

Garcia de Quevedo, gär-sē'ä dā kā-vā'dō, **José Heriberto,** South American author: b. Coro, Venezuela, March 1819; d. Paris June 1871. Educated in France and Spain, he settled in Paris, and was killed in the communard insurrection of 1871. Among his poems are: 'To Columbus'; 'To Liberty'; 'To Pius IX.'; 'Frenzy'; 'The Life to Come'; and 'The Proscript.' His dramas were well received. He wrote the novels 'The Love of a Girl' and 'Two Duels Eighteen Years Apart.'

Garcilaso de la Vega, gär-thē-lä'sō dā lä vā'gä (properly GARCIAS LASO DE LA VEGA), Spanish poet: b. Toledo 1503; d. Nice 14 Oct. 1536. According to an account given in the 'Historia de las Guerras Civiles,' the Garcilasos received their surname from their combats with Moorish heroes, in the great valley of Granada, called *La Vega*. Garcilaso soon found his proper sphere. His genius was kindled by the study of the ancients, particuarly of the Romans. Boscan had already begun to transplant the versification of the Italians into Spanish poetry. Garcilaso followed his example, and succeeded so well that he is still ranked among the best Spanish poets. Most of the events of his life may be learned from his own works. He lived for a long time in Italy, and afterward traveled through part of Germany, in the service of Charles V. In 1529 he was engaged in the expedition against Soliman, and in 1535 in that against Tunis. In the latter he received a wound in his arm, after which he remained some time in Naples. In 1536 he commanded 30 companies of infantry, and accompanied the imperial army against Marseilles. Spanish poetry is highly indebted to him; for without his aid Boscan, a foreigner, would never have succeeded in his innovations, more particularly as he had a formidable adversary in Christoval de Castillejo. His writings consist of eclogues, epistles, odes, songs, sonnets (in which he imitated Petrarch), and some smaller poems. An edition of his works, with notes, appeared in 1765, and Herrera's commentary (1580), with notes by Azara (1765).

Garcilaso (Garcias Laso) de la Vega, surnamed the INCA, Spanish historian: b. Cuzco, Peru, 1540; d. Spain 1616. He was the son of Garcilaso de la Vega, one of the conquerors of Peru, and Elizabeth Palla, a princess of the race of the incas. His mother taught him the Peruvian language, and is said to have inspired him with the idea of writing the history of his ancestors. His great work on the history of Peru is in two parts: the first bearing the title of 'Historia de las Antiquedades y Conquista de Piru: Primera Parte de los Comentarios Reales que tratan del Origen de los Incas, etc.' (1609); the second being the 'Historia general del Peru' (1616). He wrote also 'Historia de la Florida (1609).

Garcin'ia, so called after Laurent Garcin (d. 1752), a Franco-Oriental traveler, is the botanical name for a genus of guttifers, the typical one of the tribe *Garcinieæ*. It consists of opposite leaved trees, with a yellow resinous

juice, and generally unisexual flowers with four sepals, four petals, many stamens in from one to four bundles, and a 2 to 10-celled ovary with a single seed in each cell. The fruit of *G. mangostana* is the highly-prized mangosteen. The fruits of *G. pedunculata, G. cornea,* and *G. kydiana* are also eaten, but are not greatly valued. The *G. kola* of tropical Africa yield fruit and seeds similar in properties to the kola-nut. *G. cambogia* and other species of the genus furnish Gamboge (q.v.).

Garda, gär'dä, or **Benaco, Lake,** the Italian *Lago di Garda,* and the *Benacus Lacus* of the Romans, is an extensive and beautiful lake in north Italy, 33 miles long from north to south, by 3 to 11 miles broad, and 213 feet above sea-level. It forms part of the boundaries of the provinces of Verona, Mantua, and Brescia, while its north extremity enters the Austrian territory of Trent, in the Tyrol. It receives the Sarca, almost its only affluent, at its north end, and is drained by the Mincio, which issues from its southeast end near the fortress of Peschiera, and conveys its waters to the Po. Storms are not infrequent, and are sometimes violent: It is well stocked with excellent fish including salmon-trout, trout, eels, and pike. Garda is the largest lake in Italy, and attains a depth of over 1,000 feet in many places. Its shores are covered with villas and steamboats ply on it regularly between the ports of Riva, Desenzano, and Peschiera, which with Gardone-Riviera, Garda, Malcesine Salo, and the beautiful promontory of Sirmione are its most popular resorts.

Garde Nationale, gärd nä-sē-o-näl, a guard of armed citizens instituted in Paris 13 July 1789 for the purpose of preserving order and protecting liberty. At first it numbered 48,000 men, but was increased to 300,000 when it was organized throughout the whole country. Acting as a royalist and reactionary force, it was crushed by Napoleon in 1795. It was reorganized by the Directory and by Napoleon and again under the Bourbons, to whom, however, it was a source of such disquietude that it was dissolved by a royal ordinance in 1827. Under Louis Philippe it was resuscitated in its old form and contributed to his overthrow. In 1851 the national guard was again reorganized, but in 1855 it was dissolved. In 1870 the national guard of Paris was again formed for the defense of the city against the Prussians. The resistance of a section of the guard to the decree of disarmament issued under M. Thiers led to the communal war, at the close of which the guard was declared dissolved by the National Assembly (1871).

Garden, Alexander, Scottish scientist: b Charleston, S. C., about 1730; d. London 15 April 1791. He was graduated from Aberdeen; became a professor in King's College, New York (now Columbia University), and in 1755 established himself in medical practice at Charleston. From 1783 he was in London, where he became vice-president of the Royal Society. The botanical genus *Gardenia* (q.v.) was named in his honor by Linnæus. He wrote various papers on topics of botany and zoology.

Garden, Alexander, American soldier: b. Charleston, S. C., 4 Dec. 1757; d. there 29 Feb. 1829. He was for a time aide-de-camp to Gen. Greene. He wrote 'Anecdotes of the Revolutionary War in America, with Sketches of Character of Persons the most distinguished in the Southern States for Civil and Military Services' (1st series, Charleston, 1822; followed by a second series), which is one of the authorities for the history of the period, containing information hardly to be found elsewhere.

Garden. The earliest known gardens are those of Solomon which are described as having been of quadrangular form, surrounded by high walls. They contained aviaries, wells, and streams of water. The gardens of Cyrus and other Persian monarchs were of great extent, and generally laid out in romantic situations. They were also distinguished for the great diversity of their uses and products. The first allusion to terraces in gardens is to be found in the description of the celebrated hanging gardens of Babylon, anciently reckoned among the wonders of the world. Their construction is variously ascribed to Queen Semiramis and to Nebuchadnezzar. Diodorus and Strabo have given descriptions of them. They are said to have formed a square with an area of nearly four acres, and rose in terraces, supported on masonry arches, to a height of 75 feet. They were irrigated from a reservoir built at the top, to which water was lifted from the Euphrates by a screw. Fountains and banqueting-rooms were distributed throughout the numerous terraces; groves and avenues of trees, as well as parterres of flowers, diversified the scene; while the view of the city and neighborhood was extensive and magnificent. Most of the elements of a modern architectural garden are alluded to in connection with those of Babylon. The grove of Orontes, described by Strabo, must be regarded as a park or large garden in the picturesque style; it was nine miles in circumference.

In ancient Greece, gardening was rather a neglected art at first, but in process of time great advance was made. The vale of Tempé, the Academus at Athens, and other public gardens, were extremely elegant, and were ornamented with temples, altars, tombs, statues, monuments, and towers. The Greeks copied their gardening from the Persians; and the Romans, in their turn, copied that of the Greeks. Little is known of the early style of Roman gardening; the vast edifices projecting into the sea, and the immense artificial elevations, are apparently ridiculed by Cicero and Varro. About this time, however, began the cultivation of odoriferous trees and plants; and the planting of trees adjoining each other, whose odors assimilated, was then as much a study with the garener as the harmonious blending of colors at the present day.

The early French and Dutch gardens were evidently adopted from the description of Pliny's garden. The use of glass in the construction of conservatories was early known to the Greeks and Romans; and the "Gardens of Adonis," mentioned by some of their most eminent authors, were probably of this kind. Gardening, like all the other arts, languished during the Dark Ages, but with the revival of learning, the invention of printing, and the Reformation, it began again to flourish. The art was revived and patronized by the family of the Medici in Italy; and their gardens which were of the geometric and architectural style, long served as

models for most of Europe. It continued to be imitated in France, Germany, and Great Britain till the introduction of the English or natural style. In garden architecture very little progress, as far as hothouses are concerned, has been made in southern Europe, the warmth of the climate rendering them all but useless. There are, however, plant houses in many places in Spain and Portugal. The French and Dutch gardens resemble each other closely: symmetry and profuse ornament are the characteristics of both. The Dutch style is eminently adapted to the nature of the country, where there are no inequalities of surface, as in England. The French style seems to have arisen about the middle of the 17th century, during the reign of Louis XIV. The most celebrated gardener of the period was Le Nôtre, who laid out the famous gardens of Versailles. Le Nôtre's style spread rapidly into other countries. The first erection of hothouses in France occurred toward the end of the reign of Louis XIV., by M. Fagon, in the Jardin des Plantes. The first magnificent attempt at hothouse building was that of Francis I., of Austria, in 1753. They were in five ranges, extending altogether to the length of 1,290 feet, many of them being 30 feet high. From about 1760 landscape gardening, and the adoption of the English style, rapidly spread into France, Germany, and Russia, where it still prevails. See FLOATING ISLAND; FLORICULTURE; GREENHOUSE; HORTICULTURE; BREEDING, PLANT; FLOWERS; CROSS-FERTILIZATION; ETC.

Garden City, N. Y., a village on Long Island in Nassau County; on the Long Island R.R.; 18 miles east of New York. It was founded by Alexander T. Stewart as a residential town. It is the seat of the Protestant Episcopal bishop of Long Island, and contains the Cathedral of the Incarnation. Here are also the Cathedral Schools of St. Mary and St. Paul. Pop. (1901) 800.

Garden of the Gods, a small region in Colorado, near Colorado Springs, in which are seen some of the most striking effects of erosion ever found upon the globe. The "Garden" covers an area of about 500 acres, within which are strangely sculptured sandstone rocks, red and white, forms of grotesque magnificence — columns, "cathedral spires," and giant figures sometimes appearing almost as if made in human likeness. To many of these shapes have been given distinctive names suggested by their various formations. The road into the "Garden" enters through the huge "Gateway" of red rock-masses more than 300 feet in height.

Garden Snail. See SNAIL.

Garden Webworm. See WEBWORM.

Gardener, Helen Hamilton. See SMART, HELEN HAMILTON.

Gardener Bird. See BOWER-BIRDS.

Gardening, Landscape. See LANDSCAPE GARDENING.

Gardiner, gärd'nėr, **Asa Bird,** American lawyer: b. New York 30 Sept. 1839. He was educated at the College of the City of New York and New York University; during service in the Civil War attained the rank of captain and received a medal of honor for bravery; was professor of law in the United States Military Academy in 1874–9, and became district attorney of the County of New York in 1897. He has practised law in New York, and held important posts in the Society of the Cincinnati and other organizations.

Gardiner, Frederic, American Protestant Episcopal clergyman: b. Gardiner, Me., 11 Sept. 1822; d. Middletown, Conn., 17 July 1889. He was graduated from Bowdoin College in 1842, from the General Theological Seminary, New York, in 1845; was rector of Trinity, Saco, Me., 1845–7; rector of churches at Bath (1848–53) and Lewiston, Me. (1855–6); and in 1865 became professor of the literature and interpretation of Scripture in the Gambier (Ohio) Theological Seminary. In 1867 he was appointed professor of the Old Testament language and literature in Berkeley Divinity School (Middletown, Conn.), and in 1883 of New Testament interpretation and literature in that institution. He founded (1880) the Society of Biblical Literature and Exegesis, and published: 'The Island of Life' (1851); 'Diatessaron' (1871); 'The Old and New Testaments in their Mutual Relations' (1885).

Gardiner, John, American lawyer: b. Boston 1731; drowned off Cape Ann 15 Oct. 1793. He was a son of Sylvester Gardiner (q.v.). He studied law at the Inner Temple, London, and was admitted to practice at Westminster Hall. He formed an intimacy with Churchill and Wilkes, and was junior counsel of the latter at his trial in 1764, and also appeared for Beardmore and Meredith, who for writings in support of Wilkes had been imprisoned on a general warrant. In 1766 he procured the appointment of attorney-general in the island of St. Christopher, where he remained until after the American revolution, when he returned to Boston. After residing there a few years, he removed to Pownalborough, Me., which place he represented in the Massachusetts legislature until his death. As a legislator he distinguished himself by his efforts in favor of law reform, particularly the abolition of special pleading, and the repeal of the statutes against theatrical entertainments. In connection with the latter subject he published a 'Dissertation on the Ancient Poetry of the Romans,' and an accompanying speech. The abolition of the law of primogeniture in Massachusetts was due to his efforts. He was one of the most influential of the early Unitarians of Boston, and participated in the change of King's Chapel from an Episcopal into a Unitarian Congregational Church.

Gardiner, John Sylvester, American Episcopal clergman: b. Haverford West, South Wales, England, June 1775; d. Harrowgate, England, 29 July 1830. He was a son of John Gardiner (1731–93) (q.v.); accompanied his father to the West Indies, and subsequently studied in Boston, and in England under the celebrated Dr. Parr. Returning to America, he became a candidate for orders in the Protestant Episcopal Church, and in 1797 was ordained. In 1805 he became rector of Trinity Church, the chief Episcopal parish in Boston, with which he remained connected until his death. He was an accomplished scholar, and a forcible preacher. In the establishment of the 'Boston Anthology and Monthly Repository,' for which he was a frequent writer, he contributed materially to the dissemination of literary taste and culture in Boston. He was also one of the founders of the Boston 'Athenæum.' He wrote

the 'Jacobiniad,' a satire in prose and verse directed against the liberal clubs of Boston, to which, being in politics a strong Federalist, he had an antipathy.

Gardiner, Lion, English settler in America: b. 1599; d. 1633. After service in the English army, he came to America in 1635 as the representative of a land company which had a patent of territory at the mouth of the Connecticut. He built a fort to which he gave the name of Saybrook, compounded from the names of Lord Say and Sele and Lord Brook, two of the patentees, and remained in charge until 1639. He made on an island, called by him the Isle of Wight (now Gardiner's Island, township of Easthampton), the first English settlement within the limits of what is now the State of New York, and there he lived in baronial style.

Gardiner, Samuel Rawson, English historian: b. Ropley, Hampshire, 4 March 1829; d. Sevenoaks, Kent, 23 Feb. 1902. He was educated at Christ Church, Oxford, studied also at Edinburgh and Göttingen; was professor of history at King's College, London, in 1871–85, historical lecturer for the University Extension Society in 1880–94, and examiner in the Oxford final history school in 1886–9. He was elected to a research fellowship by All Souls, Oxford, in 1882, and to a similar fellowship by Merton in 1894. On Froude's death (1894) he declined appointment to the Oxford regius professorship of modern history. It is for his work of research in the history of England from 1603 to 1660 that he is best known. The results were published in instalments later assembled in various collective editions. In the course of his investigations he examined minutest details with extraordinary care. He inspected the scene of most battles which he described; he thoroughly familiarized himself with the state papers of the Record Office, and, for the study of the state papers foreign and the contents of other national archives, learned six continental languages. It is stated that he was the only one that ever read the entire collection of Thomasson tracts in the British Museum. Though himself a Liberal in politics, his writing was wholly judicial and impartial. Perhaps no other English historian ever labored more enthusiastically for historical truth. His style is clear and well-ordered, and in later volumes vigorous and often impressive. He was the first to describe in full the period of Commonwealth and Protectorate from an unprejudiced viewpoint, and he was also the first satisfactorily to explain the beginnings of the Cavalier party and the rise of the civil war. He was fortunately enabled to utilize many newly discovered sources. His work was not at first popular, but its worth was later fully recognized. In 1882 he received a civil-list pension of £150. The titles of the larger divisions of his great undertaking are: 'History of England from the Accession of James I. to the Disgrace of Chief Justice Coke' (1863); 'History of England from the Accession of James I. to the Outbreak of the Great Civil War' (1883–4); 'History of the Great Civil War' (1886–91); and 'History of the Commonwealth and Protectorate' (1894–1901), in three volumes, a fourth to be completed by Firth. He wrote also 'Cromwell's Place in History' (1897); 'Oliver Cromwell' (1899); and other works, including: 'The Thirty-Years' War' (1874); 'The First Two Stuarts and the Puritan Revolution' (1876) 'Introduction to the Study of English History' (with Mullinger, 1881); 'Constitutional Documents of the Puritan Revolution' (1889); 'Student's History of England' (1890–2); 'School Atlas of English History' (1891); 'What Gunpowder Plot Was' (1897).

Gardiner, Sylvester, American physician: b. Kingston, R. I., 1717; d. Newport, R. I., 8 Aug. 1786. He studied medicine in London and Paris, subsequently practised his profession in Boston, and opened there a drug establishment, from which the New England colonies were chiefly supplied. He was one of the early promoters of inoculation for the smallpox, and a liberal contributor for the erection of King's Chapel, Boston. He became possessed of large tracts of land in Kennebec County, Maine, and about the middle of the century was instrumental in establishing there the settlement of Pittston, a portion of which was subsequently set off into a separate town, under the name of Gardiner, where he built and endowed Christ Church. He retired from Boston on its evacuation by the British troops, but returned to the United States at the close of the Revolutionary War, and passed the rest of his life there.

Gardiner, Me., a city in Kennebec County, on the Kennebec River, and on the Maine C. R.R., six miles from Augusta. It has admirable water-power, valuable manufacturing interests, and an assessed property valuation of $4,000,000. The ice-cutting industry employs 1,000 people, with an annual output valued at $75,000. Pop. (1900) 5,501.

Gardiner's Island, N. Y., an island in a bay of the same name at the northeastern extremity of Long Island. It is part of the township of East Hampton, Suffolk County, and has an area of 3,300 acres, mostly undulating pasture land. It was colonized by an English family of the name of Gardiner in 1639 and is in possession of lineal descendants of the original settlers. Captain Kidd (q.v.) buried part of his treasures on the island in 1699, but they were recovered in the same year by the colonial authorities.

Gardner, Elizabeth Jane, American artist: b. Exeter, N. H., 1842. She was a pupil at Paris of Bougereau, Merle, and J. J. Lefebvre, and has exhibited much in the United States and foreign countries. Among her works are several portraits: 'Cinderella'; 'Fortune-Teller'; 'Moses in the Bulrushes.'

Gardner, Ernest Arthur, English archæologist: b. London 1862. He was educated at Cambridge University, and was director of the British School of Archæology at Athens, 1887–95. From 1884 he has been engaged in archæological researches in Athens, Paphos in Cyprus, Megalopolis, and elsewhere, and has lectured and written much upon Greek art and archæology.

Gardner, Eugene C., American architect: b. Ashfield, Mass., 28 March 1836. He was principal of the Academy at Tallmadge, Ohio, 1852–62. He then removed to Northampton, Mass., where he resided 1863–8, engaged in architectural work, going to Springfield, Mass., in the latter year, editing 'The Builder' 1885–7, and writing for the 'Springfield Republican.'

In 1901 he was elected a member of the Massachusetts House of Representatives. Among his works are: 'Homes and How to Make Them'; 'Illustrated Homes'; 'Home Interiors'; 'The House that Jill Built'; 'Town and Country School Houses'; and 'Common Sense in Church Building.'

Gardner, George Clinton, American engineer and railway official: b. Washington 1834; d. Richmond Hill, L. I., 12 Aug. 1904. He studied at Columbia for a time, in 1850 became connected with the survey establishing the United States and Mexican boundary from the Gulf of Mexico to the Pacific. In 1856 he was commissioned by the government assistant astronomer and surveyor of the Northwest boundary, and in this survey, for establishing and marking the 49th parallel, he gained considerable distinction. His determinations along this line form the initial points of the United States land surveys. He resigned in 1869, and subsequently was prominently identified with various railway interests. He was general manager of the Mexican National Construction Company, the Mexican National Railroad Company, and the Texas-Mexican Railroad Company, constructing much of these lines, and was connected also with other railways.

Gardner, Percy, English archæologist: b. Hackney, Middlesex, 24 Nov. 1846. He was educated at Cambridge University, was Disney professor of archæology there in 1880, and has been professor of classical archæology at Oxford from 1887. Among his publications are: 'Samos and Samian Coins' (1882); 'The Types of Greek Coins' (1883); 'New Chapters in Greek History' (1892); 'Manual of Greek Antiquities,' with Jevons (1895); 'Sculptured Tombs of Hellas' (1896); 'Exploratio Evangelica' (1899); 'Historic View of the New Testament' (1901); 'A Grammar of Greek Art' (1905).

Gardner, Mass., a town in Worcester County, including the villages of Gardner Centre, South Gardner, and West Gardner. It is situated about 25 miles north of Worcester, on the Fitchburg division of the Boston & M. R.R., two branches of which pass through the town, intersecting at the station in Gardner Centre. Gardner is the trade centre of an agricultural region, and has a large chair-manufacturing industry, with establishments employing about 3,000 people. Almost every known kind of chair is made here, and the products of this manufacture are shipped to all parts of the United States and to many foreign countries. The town has two good parks and an excellent public library. Pop. (1900) 10,813.

Garefowl, or **Great Auk.** An extinct auk (*Plautus impennis*), much like the existing razor-bill, but larger (nearly the size of a goose), with a larger bill and relatively smaller wings. It was black above and white below, with a conspicuous white patch in front of the eye. It was an expert swimmer and diver, but unable to fly on account of the very small size of its wings. The habits of the garefowl were those of auks generally, but its range was limited on the American coast to the vicinity of Newfoundland. It seems never to have lived north of the Arctic Circle; but its bones in shell-heaps testify to its former occurrence, at least in migrations, southward as far as Florida. These birds bred on small islands off the coast of Iceland, and on the Orkneys and Hebrides. Early in the 19th century they disappeared from these haunts, mainly through the persecution of fishermen and sailors who had for years killed them for food, bait, and feathers; but they lingered somewhat longer in the gulf of Saint Lawrence. Cartier's vessels visited Funk Island in 1534, and the crews easily filled two boats with the birds which they knocked down with sticks; and their abundance was mentioned as one of the inducements for settlers to come to Newfoundland. For many years the colony was ruthlessly harried, yet a few pairs survived until about 1840. A small breeding-place remained in Iceland until 1844, when the last few pairs were killed as museum specimens. The skins of this auk have been sold for $650, and an egg for $1,500. Seventy-eight specimens of the bird were preserved in museums throughout Europe and America in 1903. Consult: Newton's 'Dictionary of Birds,' article 'Garefowl,' and articles by F. A. Lucas in 'Report United States National Museum for 1887–8,' and for 1888–9.

Garfield, James Abram, twentieth President of the United States: b. Orange, Cuyahoga County, Ohio, 19 Nov. 1831; d. Elberon, N. J., 19 Sept. 1881. On his father's side he was of English Puritan descent; on his mother's, Huguenot. The father, a native of New York, settled in the "Western Reserve" in 1830, and died in 1833, leaving his widow with four small children, James being the youngest. Garfield's boyhood was passed amid the harsh but by no means destitute conditions of frontier life. He worked hard on the farm, helped in the support of the family, attended school three months each winter, and read and re-read every book which fell in his way. For a short time he was a driver and steersman on the Ohio Canal. Supporting himself chiefly by teaching, he studied successively at Geauga Seminary 1849, Eclectic Institute, Hiram, Ohio (now Hiram College), 1851–4, and Williams College, Mass., entering the junior class in 1854 and graduating with high honors in 1856. Returning to Ohio, he taught the classics at Hiram Institute 1856–7, and became its president 1857–9. Coincident with his teaching he studied law, was admitted to the bar in 1859, and, resigning his presidency, was elected to the Ohio State senate. The Civil War breaking out, he threw himself enthusiastically into the Northern cause, was commissioned lieutenant-colonel of the 42d Ohio, and given command of a brigade, with orders to operate as an independent force in eastern Kentucky, December 1861. With a force of 1,100 men and no artillery he signally defeated 5,000 Confederates under the veteran general, Humphrey Marshall, driving them from fortified positions of their own choosing, 10 Jan. 1862. For this exploit Lincoln promoted him brigadier-general. Subsequently he took part in the battle of Shiloh, in the operations around Corinth, and served with distinction on several courts-martial at Washington, one being that of Gen. Fitz-John Porter (q.v.). Appointed chief of staff to Gen. Rosecrans, February 1863, his notable services at Chickamauga (see CHICKAMAUGA, BATTLE

OF) caused Lincoln to make him a major-general, 19 Sept. 1863. In 1862 his home district had elected him to Congress. Thus, within six years he had been president of a college, State senator, major-general, and representative-elect, a combination of honors without parallel in the national annals. Upon the advice of Lincoln and Stanton he resigned his major-general's commission 5 Dec. 1863 and took his seat as a representative on December 7. In this field his talents and genius found their true sphere. He stepped to the front at once, taking a prominent part in every debate of importance, and becoming an authority on questions of finance; tariff, education, and constitutional rights. Always the champion of sound money, his speech in March 1866 clearly outlined the policy which resulted in the resumption of specie payments 1 Jan. 1879. An eminent contemporary has well said of Garfield's speeches that they are a compendium of the political history of the time, and would give a connected history and complete defense of the important legislation of the 17 eventful years that comprised his legislative career. He was eight times re-elected to Congress, serving on such important committees as those on military affairs and on ways and means, and was the first chairman of the committee on banking and currency. In the Reconstruction period he steadily opposed the theories of President Johnson (see JOHNSON, ANDREW); in 1876 he went to New Orleans at President Grant's request to watch the counting of the Louisiana vote, and in 1877 was chosen by acclamation one of the two members of the Electoral Commission allotted to the House of Representatives. In the 45th Congress Garfield displayed masterly qualities as a leader of opposition. His speech at Faneuil Hall, Boston, in 1878 on the national finances was circulated by thousands as a campaign document. On 13 Jan. 1880 the Ohio legislature unanimously elected him United States Senator to succeed Hon. Allen G. Thurman (q.v.), and his last speech in Congress was delivered 23 April 1880. At the Republican National Convention at Chicago, 2–8 June 1880, he headed the Ohio delegation, nominated John Sherman (q.v.) for the Presidency, opposed the nomination of Gen. Grant for a third term, and was himself nominated on the 36th ballot as a compromise candidate. Contrary to all precedent, Garfield himself took part in the campaign that followed, making some 70 speeches in all, chiefly extemporaneous. At the November election he received 214 electoral votes to 155 given his Democratic opponent, Gen. Hancock. The first months of Garfield's administration were disturbed by the opposition of the New York senators to certain of his appointments. Senators Conkling and Platt claimed the right to control the Presidential appointments in their State. This the President refused to concede. The senators resigned and appealed to their legislature to vindicate their attitude by a re-election, but failed to get it. On the morning of 2 July 1881, while in the Baltimore & Ohio station at Washington, on his way to New England, where he intended to deliver the commencement address at Williams College, President Garfield was shot by Charles Jules Guiteau (q.v.), a disappointed office-seeker. For weeks he lingered between life and death, suffering the greatest agony but bearing it with a magnificent fortitude that won the admiration and sympathy of the civilized world. A removal to Elberon, N. J., in the hope that the sea air might benefit him was of no avail. Blood poisoning set in on 15 September, and he died on the 19th at 10:30 P.M. In February 1882 an impressive memorial service was held in the House of Representatives, the Hon. James G. Blaine delivering a commemorative address, which, for eloquence, dignity, and truth, has rarely been equaled on such occasions. Garfield's body lies in a beautiful cemetery in Cleveland, Ohio, a stately monument marking the spot. His life was the fullest realization of the opportunities of American citizenship. Rising from nothing, by his own exertions he won high places in various spheres and filled them all adequately and with dignity.

No definitive 'Life' has yet appeared, the biographies of Garfield by J. M. Bundy, C. C. Coffin, and J. R. Gilmore (all 1880) being incomplete and unsatisfactory. His 'Works' have been edited by Prof. B. A. Hinsdale (1882–3).

W. N. C. CARLTON,
Librarian Trinity College, Hartford.

Gargano, gär-gä'nō (ancient Garganus), a mountainous peninsula, the "spur" of Italy, in the province of Foggia, jutting out into the Adriatic Sea, and attaining in Monte Calvo a height of nearly 4,000 feet. Bee-keeping is yet as generally engaged in as in the time of Horace. The district is visited mainly by pilgrims to a shrine of Saint Michael on Monte Saint Angelo. It is about 50 miles long and 27 miles broad.

Garguntua, gär-gan'tū-ä, the hero of Rabelais' satire, so named from his father exclaiming "*Que grand tu as!*" "How large (a gullet) thou hast!" on hearing him cry out, immediately on his birth, "Drink, drink!" so lustily as to be heard over several districts. It required 900 ells of linen for the body of his shirt, and 200 more for the gussets, 1,100 cow hides for the soles of his shoes, and he picked his teeth with an elephant's tusk.

Gargoyle, Gargoil, or **Gurgoyle** (French *gargouille* = the weazand of the throat), in architecture, a quaintly-formed head of a man or animal, employed as a decorative spout for the rain-water from a roof. The most common form was that of a dragon projecting from the roof-gutter, but the varieties are innumerable. They were used in all styles of architecture, and are many of them of a most hideous appearance.

Garfield Monument, a monument erected as a memorial to President Garfield, in the Lakeview Cemetery at Cleveland, Ohio. See CLEVELAND.

Garibaldi, Giuseppe, joo-sĕp'pĕ gä-rē-bäl'dē, Italian patriot: b. Nice, France, 4 July 1807; d. island of Caprera, Italy, 2 June 1882. His father being a poor fisherman, he received little education, and for a number of years was a sailor on various trading vessels. In 1834, being condemned to death for his share in the

JAMES ABRAM GARFIELD,

TWENTIETH PRESIDENT OF THE UNITED STATES.

schemes of Mazzini, he escaped to Marseilles and finally went to South America. In the service of the Republic of Rio Grande against the Brazilians he became known as a brilliant leader, and with his famous Italian legion he subsequently gave the Montevideans such effective aid against Buenos Ayres as to earn the title of "hero of Montevideo." In 1848 he returned to Italy, raised a band of volunteers, and harassed the Austrians till the re-establishment of Austrian supremacy in Lombardy. In the spring of 1849 he proceeded to Rome to support Mazzini's republic. He was appointed to command the forces, but the odds were overwhelming, and after a desperate defense of 30 days Garibaldi escaped from Rome with 4,000 of his followers. He reached the United States, and was for several years in command of a merchant vessel. He then purchased a part of the small island of Caprera, off the north coast of Sardinia, and made this his home for the rest of his life. Latterly the subscriptions of his admirers enabled him to become owner of the whole island.

In the war of 1859, Garibaldi and his Chasseurs of the Alps did splendid service; and on the revolt of the Sicilians in 1860 he crossed to the island, wrested it after a fierce struggle from the king of Naples, recrossed to the mainland and occupied Naples, where he was proclaimed dictator of the Two Sicilies. He readily acquiesced in the annexation of the Two Sicilies to Italy, and declining all honors retired to his island farm. In 1862 he endeavored to force the Roman question to a solution, and entered Calabria with a small following, but was taken prisoner at Aspromonte by the royal troops. He was soon released, however, and returned to Caprera. In 1864 he received an enthusiastic welcome in Great Britain. In 1866 he commanded a volunteer force against the Austrians in the Italian Tyrol, but failed to accomplish anything of consequence. Next year he attempted the liberation of Rome, but near Mentana was defeated by the French and pontifical troops, and was again imprisoned by the Italian government, but soon pardoned and released. In 1870 he gave his services to the French republican government against the Germans, and at the end of the war was elected a member of the French Assembly, but speedily resigned his seat and returned to Caprera. Rome now became the capital of united Italy, and here in January 1875, Garibaldi took his seat in the Italian Parliament. The latter part of his life was spent quietly at Caprera. After 1870 he wrote two or three novels of very mediocre quality. His autobiography was published in 1887, and translated into English with a supplementary biography in 1889.

Garibaldi (fish), a small, brilliantly colored, edible fish (*Hypsypops rubicundus*), scarlet when adult, which dwells in rocky pools along the coast of southern California, hiding and finding its food among the seaweeds.

Garigliano, gä-rēl-yä'nō, a river in southern Italy, formed by the junction of the Liri and Sacco near Pontecorvo. It flows southeast and southwest, and after a course of 40 miles falls into the Gulf of Gaëta.

Garland, Augustus Hill, American lawyer: b. near Covington, Tenn., 11 June 1832; d. Washington, D. C., 26 Jan. 1899. He opposed secession as a policy, but was afterward elected to the Confederate Senate, which office he held till the close of the War. In 1874 he was elected governor under the new Constitution of Arkansas, and in 1885 became attorney-general in the cabinet of President Cleveland.

Garland, Hamlin, American novelist: b. West Salem, Wis., 16 Sept. 1860. His works include: 'Main Traveled Roads' (1891); 'A Spoil of Office'; 'Prairie Folks'; 'Jason Edwards' (1891); 'A Member of the Third House' (1892); 'Prairie Songs' (1893); 'A Little Norsk' (1893); 'Crumbling Idols' (1894); 'Rose of Dutcher's Coolly' (1895); 'Wayside Courtships' (1897); 'The Eagle's Heart' (1901); 'Captain of the Gray Horse Troop' (1902); 'The Tyranny of the Dark' (1904); etc.

Garland, Landon Cabell, American educator: b. Livingston, Va., 21 March 1810; d. 1895. He was graduated at Hampden-Sidney College, Virginia, was professor of chemistry at Washington College in that State 1830–3, at Randolph-Macon College 1833–5, and became president of the latter in 1835. In 1847–53 he was professor of astronomy and mathematics at the University of Alabama, in 1855–66 its president; later was professor of physics in the University of Mississippi, and chancellor of Vanderbilt University.

Garlic (*Allium sativum*), a species of onion cultivated in Europe since the year 1551. The leaves are grass-like, and differ from those of the common onion in not being fistulous. The stem is about two feet high, terminated by a head composed principally of bulbs instead of flowers; the flowers are white; the root is a compound bulb, consisting of several smaller bulbs, commonly denominated cloves, enveloped by a common membrane. Garlic has a strong, penetrating odor, and a pungent acrid taste. It differs from the onion only by being more powerful in its effects. In warm climates, where garlic is considerably less acrid than in cold ones, it is much used both as a seasoning and as food. In the south of Europe, particularly in Spain, and among Italians in the United States, it enters into the composition of almost every dish, not only among the common people, but among the higher classes of society. At all times, however, while it has been prized by some nations it has been detested by others, as by the ancient Greeks. Its cultivation is easy, and it is reproduced by planting the radical or floral bulbs. Its medicinal virtues are celebrated.

Garlic, Oil of. When the leaves, seeds, or bulbs of garlic and other allied plants are distilled with steam, about 0.2 per cent of a brown oil, with acrid taste and strong disagreeable odor, passes over. By purification it is obtained as a pale yellow oil having the odor of garlic, and it is then found to consist of the sulphide of allyl $(C_3H_5)_2S$. This oil is nearly related to the pungent oil of mustard, C_3H_5NCS, an isomer of the sulphocyanide of allyl, and is of much interest chemically, but it is of no importance from an industrial point of view.

Garman, Harrison, American naturalist: b. Lena, Ill., 27 Dec. 1858. He was graduated at the State Normal University and studied later at Johns Hopkins University. He has held many professional positions, among them being entomologist and those of professor of zoology

and entomology at Kentucky State College, 1892-6, and State entomologist of Kentucky since 1897.

Garman, Samuel, American naturalist: b. Indiana County, Pa., 5 June 1846. He was graduated at the Illinois State Normal University in 1870, and became assistant in herpetology and ichthyology in the Museum of Comparative Zoology, Cambridge, Mass., in 1873. His works include: 'The Reptiles and Batrachians of North America'; 'Chlamydoselachus'; 'The Evolution of the Rattlesnake'; etc.

Garner Case, 1856, the most tragic of the fugitive-slave cases. Simon Garner, his wife, and his son Robert, slaves of John Marshall of Kentucky, and Robert's wife Margaret and their four children, slaves of A. R. Gaines, ran away, crossed the Ohio on the ice, and took refuge with a Cincinnati colored man. Gaines tracked them, secured a warrant, and with a deputy marshal and a band of assistants attacked the house. After a desperate fight the fugitives were overpowered, one of the posse being badly wounded; but Margaret, who had shared in the conflict, found time before her capture to murder one of the children, severely cut the throats of two others, and considerably bruised the baby, to keep them from returning to slavery. In sympathy with them, and to establish their freedom as denizens of Ohio, a Cincinnati judge issued a writ of habeas corpus, and the grand jury indicted Margaret for the murder of her child, and her husband and his father as accessories. The United States fugitive-slave law of 1850 prevailed, however; the slaves were given back to their owners and sent down the river. On the voyage Margaret jumped overboard with the baby; she was rescued, but the child was lost, at which she expressed satisfaction.

Garnet. See GEMS.

Gar'nett, James Mercer, American philologist: b. Aldie, Va., 24 April 1840. He was graduated at the University of Virginia in 1859; served in the Confederate army during the Civil War; and was professor of English language and literature in the University of Virginia 1882-96. He is the author of: 'Translation of Beowulf'; 'Elene and Other Anglo-Saxon Poems'; 'History of the University of Virginia.'

Garnett, Richard, English poet and librarian: b. Lichfield, Staffordshire, 27 Feb. 1835; d. London, 13 April 1906. He was appointed in 1851 assistant in the printed book department of the British Museum, became superintendent of the reading-room in 1875, but resigned in 1884 to devote himself more exclusively to the printing of the 'Museum Catalogue,' of which he had had charge from its commencement. He published: 'Primula: a Book of Lyrics' (1858); 'Egypt and Other Poems' (1859); 'Poems from the German' (1862); 'Relics of Shelley' (1862); 'Idylls and Epigrams' (1869); 'Selections of Shelley's Poems' (1880); 'Letters' (1882); 'Life of Carlyle' (1887); 'Life of Emerson' (1887); 'Twilight of the Gods' (1888); 'Life of Milton' (1890); 'Iphigenia in Delphi' (1891); 'Poems' (1893); 'William Blake: Painter and Poet' (1895); 'The Age of Dryden' (1895); 'One Hundred and Twenty-four Sonnets from Dante, Petrarch and Camoens' (1896); 'Richmond on the Thames' (1896); 'Life of Edward Gibson Wakefield' (1898); 'History of Italian Literature' (1898); 'Essays in Librarianship and Bibliography' (1899); 'The Queen and Other Poems' (1901); 'Essays of an Ex-Librarian' (1901); etc. He also contributed extensively to the magazines and cyclopædias. He resigned from the Museum in 1899.

Garnett, Robert Selden, American soldier: b. Essex County, Va., 16 Dec. 1819; d. Carrick's Ford, Va., 13 July 1861. Graduated from the United States Military Academy in 1841 and made brevet 2d lieutenant of artillery, he served on the northern frontier during the Canadian border disturbances, and distinguished himself in the war with Mexico (1846-8), receiving the brevet of major for his conduct at Buena Vista. He was transferred to the Seventh infantry in 1848, fought in Florida against the Seminoles, and was commandant at West Point in 1852-4. In 1855 he was promoted major of infantry, and in 1856 commanded the expedition against the Indians of Puget Sound. At the outbreak of the Rebellion in 1861 he resigned his commission, and was made adjutant-general, with colonel's rank, to organize the Virginia forces. Shortly afterward he was appointed brigadier-general, C. S. A., and given command of the troops in the western part of Virginia. While endeavoring to retreat to Beverly, he was overtaken by the Federals at Carrick's Ford, Cheat River, and took command of a detachment with which he sought to cover the retreat. His force was routed, and he was killed during the combat.

Garnett, Kan., city and county-seat of Anderson County, on the Pottawattomie River, and on the Missouri P. and the Atchison, T. & S. F. R.R.'s, 45 miles northwest of Fort Scott. It has good educational institutions, including a United Presbyterian college. There are large manufactures of furniture, and also of cheese. Pop. (1900) 2,078.

Garnier, Jean Louis Charles, zhŏṅ loo-ē shärl gär-nē-ā, French architect: b. Paris 6 Nov. 1825; d. 4 Aug. 1898. He was a pupil of Levieil and Lebas at the Beaux-Arts, won the Prix de Rome in 1848 with his design for a conservatory of arts and industries, traveled in Italy, Turkey, and Greece, and in 1861 won the competitive prize for plans of the new Paris Opera. In 1863-74 he superintended the construction of this costly and important work, whose chief feature is its grand staircase, but which is by some thought to be overladen with accessories of painting and sculpture. In addition to this, his principal achievement, he designed buildings public and private at Paris and elsewhere. He was the author of: 'Travers les Arts' (1869); 'L'habitation humaine,' with Ammann (1892); and editor 'Le nouvel Opéra de Paris' (1876-81).

Garnier, Marie Joseph François, commonly known as FRANCIS, French explorer: b. Saint-Etienne 25 July 1839; d. Hanoi, Tongking, China, 2 Dec. 1873. He entered the French navy, served in the war with China in 1860-2, and became a civil officer in the newly established colony of Cochin-China. In 1866 he was appointed to assist Capt. Doudart de Lagrée in an exploring expedition which set out from the

coast of Cambodia and proceeded through Yunnan to Shanghai, the purpose being to open a highway of trade. Garnier explored the river Mekong, and, on the death of Doudart de Lagrée, assumed command of the expedition, which he brought successfully along the Yang-tse-kiang to Shanghai. The geographical societies of France and Great Britain bestowed numerous honors upon him. He took part in the defense of Paris in 1870–1, and again undertook explorations in China. The governor of Cochin-China empowered him to negotiate a treaty with the viceroy of Tongking. Upon the refusal of the viceroy to open negotiations, Garnier captured Hanoi, the capital, and achieved further victories with a force of but 120. He was finally killed in an ambush. His 'Voyage d'Exploration en Indo-Chine pendant 1866–8' (1873) is a notable book.

Garnierite, a green, amorphous mineral, one of the most important ores of nickel. It is a hydrous silicate of nickel and magnesium, the ratio of the two metals varying widely. It is soft and very brittle and has a specific gravity of 2.3 to 2.8. It is extensively mined in New Caledonia, and also occurs in large quantities in Douglas County, Ore., and Jackson County, N. C. It was named after the French geologist, Garnier.

Garnishment, in law, a process by which a third person, in whose possession the effects of the defendant are attached, is warned not to turn over such effects to the defendant, but to appear in court and give information. This process is controlled by statute in the States where it exists, and the demands of the statutes must be fully met by any plaintiff seeking to make use of the process. The process is called in some States trustee process, in others factorizing, and in still others attachment, the more general title. The third party, who is known as the garnishee, is liable for only such property as is not encumbered by trusts and may be delivered by the officer serving said process. Virtually, the process is a secondary suit brought by the suing creditor against the third party, or garnishee, the creditor claiming the rights of the defendant in the primary action.

Garofalo, Benvenuto, bān-vā-noo'tō gä-rō'fä-lō (originally Benvenuto Tisi da Garofalo), Italian painter: b. Ferrara 1481; d. there 6 Sept. 1559. In this city and in Cremona he cultivated his talents for painting; but the masterpieces of art in Rome exercised the greatest influence upon him. In the year 1505 he is said to have returned to Rome, and to have formed a very close intimacy with Raphael, who often made use of his assistance. He afterward painted for Alfonso I., in his native city. Garofalo's works show the influence of all the schools, particularly of the Lombard, and still more so of Raphael's, whom he surpassed in coloring. Most of his works are at Rome. Several of them, however, are in the galleries of Vienna and Dresden.

Garonne (Lat. *Garumna*), a river of southwestern France, the chief one of that section; rising in the Pyrenees, at the foot of Mount Maladetta, in the Val d'Aran, within the Spanish border. It enters France at a distance of 26 miles from its mouth. The Garonne flows in a general northeasterly direction through the department of Haute-Garonne to Toulouse, whence it proceeds in a northwesterly course. Some 20 miles below Bordeaux it forms a junction with the Dordogne; it then takes the name Gironde, and enters the Atlantic Ocean by an estuary of 50 miles in length. The complete length of the river is about 400 miles. Ocean-going steamers may ascend to Bordeaux, and the river is navigable to Toulouse and beyond. From Toulouse the Canal du Midi extends to the Mediterranean. Several destructive floods have taken place, that of 1875 having caused special damage. With its 32 tributaries the Garonne offers a system of waterways navigable for more than 1,400 miles, — a total exceeding that afforded by any other French stream. The total drainage area approaches 38,000 square miles.

Garrard, Kenner, American soldier: b. Cincinnati, Ohio, 1830; d. there 15 May 1879. He was graduated from the United States Military Academy in 1851, was made brevet 2d lieutenant in the artillery, but in 1852 was transferred to the dragoons, and after service, largely in the Northwest, was made captain of cavalry in 1861. During the early part of the Civil War he was in the commissary-general's office at Washington, and in 1861–2 commandant at West Point. In September 1862 he was commissioned colonel of the 146th New York volunteers, which he commanded at Fredericksburg, Chancellorsville, and Gettysburg. For services in the last named battle he was brevetted lieutenant-colonel. In 1863 he was promoted brigadier-general of United States volunteers, and afterward he participated in the combat at Rappahannock Station and the Mine Run operations. He took part, also, in the invasion of Georgia, was brevetted colonel for services in the expedition against Covington, Ga., and from December 1864 to July 1865 commanded the second division of the Sixteenth army corps. He distinguished himself by his efficiency in the battle before Nashville, and in the operations against Mobile; led the storming column which finally captured Blakely (9 April 1865); and was in command of the district of Mobile in August–September 1865. Mustered out of the volunteer service in August 1865, he was assistant inspector-general of the department of the Missouri in 1866, and in November 1866 resigned from the army, being at that time major, with the brevet of major-general for gallant and meritorious services in the field during the Rebellion.

Garrett, Alexander Charles, American Protestant Episcopal bishop: b. Ballymot, County Sligo, Ireland, 4 Nov. 1832. He was graduated from Trinity College, Dublin, in 1855; was ordained priest in 1857; held the curacy of East Worldham, Hampshire, in 1856–9; was a missionary in British Columbia in 1859–69; rector St. James', San Francisco, in 1870–2; and dean of Trinity Cathedral, Omaha, 1872–4. In 1874 he became missionary bishop of northern Texas, and subsequently bishop of Dallas. His publications include: 'The Eternal Sacrifice'; 'The Philosophy of the Incarnation'; 'Historical Continuity.'

Garrett, Edmund Henry, American artist: b. Albany, N. Y., 19 Oct. 1853. He was a pupil in Paris of Laurens, Boulanger, and J. J. Lefebvre, and exhibited much in America and at the Paris Salon. In 1890 he received a medal at Boston. He also published: 'Romance and

Reality of the Puritan Coast' (1897); and 'The Pilgrim Shore' (1900).

Garrett, John Work, American railway official: b. Baltimore 1820; d. 1884. He studied at Lafayette College, became a director of the Baltimore & Ohio Railroad (1857), and its president, greatly developed the road, and made it during the Civil War a most important medium for the transportation of Federal supplies and troops.

Garrett, William Robertson, American educator: b. Williamsburg, Va. 12 April 1839. He was graduated from William and Mary College in 1858, studied law in the University of Virginia, served in the Confederate army, was long occupied in educational work in the South, and was State superintendent of public instruction in Tennessee 1891–3. In 1895 he became professor of American history in Peabody Normal College, and in 1899 dean of the institution. He has published 'The South Carolina Cession and the Northern Boundary of Tennessee' (1884); 'History of Tennessee,' with Goodpasture (1900).

Garrick, David, English actor: b. Hereford, England, 19 Feb. 1717; d. London 20 Jan. 1779. His grandfather was a French refugee, his father a captain in the army. He was educated at the grammar school at Lichfield. He gave an early proof of his dramatic tendency by inducing his school-fellows to act the 'Recruiting Officer,' in which he himself took the part of Sergt. Kite, being then only 12 years of age. Later he was placed with a brother under Dr. Samuel Johnson. In 1741 he joined Giffard's company at Ipswich, where under the name of Lyddal he played with uniform success.

At this time the stages of the metropolis were but indifferently supplied with leading performers, so that when Giffard, who was manager of a theatre in Goodman's-fields, introduced his accomplished recruit there, 19 Oct. 1741, the effect was immediate and decisive. He judiciously chose the part of Richard III., which did not require that dignity of person in which he was deficient, while it gave him scope for all the strong marking of character and changes of passion in which his principal excellence consisted. He at the same time adopted a natural mode of recitation, which was a daring innovation on the part of a new performer before audiences accustomed to the artificial declamation of the school which preceded him. He afterward visited Dublin, where his success was even greater than in the metropolis, and in 1745 became joint manager with Sheridan of a theatre there. In 1746 he was engaged for the season at Covent Garden, and at its close purchased Drury Lane, and opened it 15 Sept. 1747, with the 'Merchant of Venice,' to which Dr. Johnson wrote a prologue for the occasion. This period formed an era in the English stage, from which may be dated a comparative revival of Shakespeare, and a reform both in the conduct and license of the drama. In 1749 he married Eva Marie Violetti (1724–1822), and his married life seems to have been happy. The remainder of his theatrical career was an uninterrupted series of success and prosperity. He had written, while an actor, his farces of 'The Lying Valet'; 'Lethe,' and 'Miss in Her Teens'; and in 1766 he composed, jointly with Colman, the excellent comedy of 'The Clandestine Marriage.' The year 1769 was signalized by the famous Stratford jubilee — a striking proof of his enthusiasm for Shakespeare. It occupied three days at Stratford, and its representation at the theatre lasted for 92 nights. The last part which he performed was Don Felix in 'The Wonder,' for the benefit of the theatrical fund. At the conclusion of the play he addressed a brief farewell to the audience. The general feeling with which this was delivered and received rendered it truly impressive. His remains were interred in Westminster Abbey, his funeral being attended by a numerous assemblage of rank and talent. As an actor Garrick has rarely been equaled for truth, nature, and variety and facility of expression, for which his countenance appears to have been admirably adapted. Expression and the language of passion formed his great strength, as he was equaled by many of his contemporaries in the enunciation of calm, sentimental, and poetical declamation. His literary talents were respectable, but not eminent; besides the pieces already mentioned he wrote some epigrams, a great number of prologues and epilogues, and a few dramatic interludes, and made many and sometimes judicious alterations of old plays. A collection of his works was published in London (1768–98), and his correspondence 1831–2. See Knight, 'Life of David Garrick' (1894).

Gar'rigan, Philip Joseph, American Roman Catholic prelate: b. Cavan, Ireland, 8 Sept. 1840. While he was still very young the family came to America and settled in Massachusetts and in the schools of that State he received his elementary education. He afterward studied at Saint Charles' College, Maryland, later taking an ecclesiastical course at Saint Joseph's seminary, Troy, N. Y., where on 10 June 1870 he was ordained priest. He was then appointed assistant in Saint John's Church, Worcester, Mass. In 1873 he became vice-president of the Troy Seminary and after three years was recalled to the diocese of Springfield. In 1888 he was chosen vice-rector of the Catholic University, Washington, D. C., and continued to hold the vice-rectorship until 21 March 1902, when Pope Leo. XIII. selected him for the newly-created episcopal see of Sioux City. He was consecrated bishop at Springfield, Mass., 25 May 1902. Though but two years established, the diocese now (1905) has a Catholic population of 50,000; 103 priests; 123 churches; 45 parochial schools; 1 hospital, and a Young Ladies' Home.

Garrison, George Pierce, American historical scholar: b. Carrollton, Ga., 19 Dec. 1853. He was educated at Sewanee College, Tenn., and the universities of Edinburgh and Chicago; became instructor in English and history in the University of Texas in 1884, assistant professor of history in 1888, and professor in 1897. He has published: 'The Civil Government of Texas' (1898); 'Texas,' in 'American Commonwealths' series (1903).

Garrison, Wendell Phillips, American editor: b. Cambridgeport, Mass., 4 June 1840. After graduation from Harvard (1861), he became literary editor of the New York 'Nation' in 1865. Among his publications are: 'What

Mr. Darwin Saw in His Voyage Around the World' (1879); 'Bedside Poetry' (edited, 1887); the 'Life of William Lloyd Garrison,' his father, with his brother, F. J. Garrison (1885); 'The New Gulliver' (1898).

Garrison, William Lloyd, American reformer: b. in Newburyport, Mass., 12 Dec. 1805; d. New York 24 May 1879. He was apprenticed to a shoemaker, but eventually became a compositor on the Newburyport 'Herald,' an occupation which suited his taste; he soon made himself master of the mechanical part of the business, and when only 16 or 17 began to write for the 'Herald.' His contributions, which were anonymous, were favorably received, and he soon commenced to send articles to the Salem 'Gazette' and other papers, drawing the attention of political circles by a series of articles under the signature "ARISTIDES," with the view of removing the almost universal apathy on the subject of slavery. In 1824 he became editor of the 'Herald,' and some of Whittier's earliest poems were accepted by him, while their author was yet unknown to fame. In 1827 he became editor of the 'National Philanthropist,' the first American temperance journal, and afterward of a journal in support of the election of John Quincy Adams. With Mr. Lundy, a Quaker, he then started at Baltimore the paper called the 'Genius of Universal Emancipation' (1829). The vigorous expression of his anti-slavery views in this last paper led to his imprisonment for libel, from which he was released by Mr. Tappan, a New York merchant, who paid his fine. He now prepared a series of emancipation lectures, subsequently delivered in New York and other places. He returned to Boston, and in 1831 started 'The Liberator,' without capital or subscribers, a paper published weekly with the aid of one assistant and a negro boy, and with which his name is inseparably associated, and which he carried on for 35 years, until slavery was abolished in the United States. In 1832 appeared his 'Thoughts on African Colonization,' and in the same year he established the American Anti-Slavery Society. For several years the mail brought hundreds of letters to Garrison, threatening his assassination if he did not discontinue 'The Liberator'; the legislature of Georgia offered a reward of $5,000 to any one who should prosecute and bring him to conviction in accordance with the laws of that State; in 1835 he was severely handled by a Boston mob, and the mayor of that city was constantly appealed to from the South to suppress his paper. In spite of all, he successfully persevered. In 1833 he visited Great Britain, and again, in the furtherance of his anti-slavery opinions, in 1846 and 1848. The diverging views of the anti-slavery party, as to whether a political platform should be adopted, and as to the voting and speaking of women, rent the body for a time, but on 1 Jan. 1863 Lincoln's proclamation of freedom to the slaves as a military measure placed the civil struggle on an anti-slavery basis. In 1865, when Garrison's labors had been completely successful, and after the total abolition of slavery in the United States, his friends presented him with the sum of $30,000 as a memorial of his services.

A bronze statue has been erected to his memory in Boston. Some 'Sonnets and Other Poems' by him were published in 1847, and 'Selections from Writings and Speeches' in 1852. See Johnson, 'William Lloyd Garrison' (1882); 'William Lloyd Garrison: the Story of His Life,' by his children (1885–9); and poems to his memory by both Whittier and Lowell. The reformer's character, as revealed in the accounts of his life, shows his great humanitarian schemes to have been the inevitable outcome of a sensitive conscience, a humane spirit, and an overpowering sense of justice.

Garrote, ga-rŏt', a mode of punishment in Spain by strangulation, the victim being placed on a stool with a post or stake (Spanish, *garrote*) behind, to which is affixed an iron collar with a screw; this collar is made to clasp the neck of the criminal, and drawn tighter by means of the screw till life becomes extinct. This word, with the spelling *garrotte,* has of late years become naturalized in Great Britain and the United States as a term for a species of robbery effected by suddenly springing upon and throttling the victim, and stripping him of his property.

Garrupa, ga-roo'pa, the Spanish name, in the West Indian region adopted as generic, and also corrupted into "grouper" of the great black jewfish (*Garrupa nigrita*). See JEWFISH.

Garter King-of-Arms, the head of the heraldic establishment in England, consisting of three kings-of-arms — Garter, Clarencieux, and Norroy, and the herald of the military order of the Garter. The office of garter king-of-arms was instituted by Henry V. in 1417. The duties of the garter king-of-arms are principally to grant heraldic supporters, to arrange funerals, and to present the order of the Garter to foreign princes.

Garter, Order of the, the highest and most ancient order of knighthood in England. Two stories are told of its origin. The first is that Richard I. at the siege of Acre caused some of his officers to tie leather thongs around their legs as a distinction. The origin of the order is, however, generally attributed to Edward III., and the legend runs that the Countess of Salisbury having dropped her garter while dancing, the king restored it after putting it round his own leg, amid the jesting of courtiers, with the words, *Honi soit qui mal y pense* —"Shame be to him who thinks evil of it." The date of the foundation or restoration by Edward III. of the order is not exactly determined; 1344 is given by Froissart, while other authorities, founding cn the statutes of the order, assign it to 1350. In the former year it appears that a festival was held, and a society or company instituted, called the Company of Saint George, with the design of furnishing soldiers of fortune to assist King Edward in asserting his claim to the crown of France, but it seems probable that the organization of the order as an order of chivalry was completed in 1350. The statutes of the order have been repeatedly revised. The order is said to have been founded in honor of the Holy Trinity, the Virgin Mary, St. Edward the Confessor, and St. George of Cappadocia, its special patron. Until the reign of Edward VI. its common title was the Order of St. George, which it still bears, besides that of the Garter. The original number of knights, 26, including the sovereign, its permanent head, is still retained, except that since 1786 princes of the blood are

admitted as supernumerary members. The order is frequently conferred on foreign sovereigns. The vestures and insignia of the order are: The emblem of the order, the garter, a dark-blue ribbon edged with gold, bearing the motto, and with a buckle and pendant of gold richly chased; worn on the left leg below the knee; the mantle of blue velvet, the length of the train distinguishing the king; the surcoat and hood of crimson velvet, the hat of black velvet, with plume of white ostrich feathers, having in the centre a tuft of black heron's feathers, and fastened to the hat with a band of diamonds; the collar of gold consisting of 26 pieces, each in the form of a garter, with the badge of the order, called the George, pendent from it — a figure of St. George on horseback fighting the dragon — the lesser George being worn on a broad blue ribbon over the left shoulder. The star, formerly only a cross, is of silver, and consists of eight points, with the cross of St. George in the centre, encircled by the garter. A star is worn by the knights on the left side when not in the dress of the order. The officers of the order are the prelate, the Bishop of Winchester; the chancellor, the Bishop of Oxford; the registrar, Dean of Windsor; the garter king-of-arms, and the usher of the black rod. There are a dean and 12 canons, and each knight has a knight-pensioner.

Garter-snake, or **Grass-snake.** Names given in the United States to several small striped harmless serpents of the genus *Eutœnia,* especially *E. sirtalis,* which abounds in all temperate parts of the continent from Guatemala to Canada, and is exceedingly variable. This species varies in color from light-green through olivaceous to black, marked by three stripes, but only the one along the spine is well defined, those on the sides being often obscure, broken, or altogether absent. The spaces between these may be spotted in double rows, or not at all; and the belly, usually light greenish-blue, may be darker, almost to blackness. Some varieties have a metallic lustre. The ordinary eastern specimens are olive-brown, with dull spots and stripes. It is everywhere abundant, frequenting grassy meadows, farm-fields, roadsides and gardens, where it searches for mice as the principal part of its food, but it eats insects, small toads and frogs, and the eggs and young of birds whose nests are on or near the ground, for it is not a bold climber. It is abroad by day as well as by night, and itself forms the prey of such larger snakes as the blacksnake and king-snake. In the West it eats all the young gophers and ground-squirrels it can get, and in these habits commends itself to the protection of agriculturists. These snakes are extremely active and swift, as they must be not only to capture their prey, but to avoid being caught by the larger blacksnakes, king-snakes, and the like which pursue them. They swim well and hide clearly in water, and in many habits, as in structure, resemble the water-snakes (*Natrix*); and like them they are pugnacious, and quick to bite when handled, but their teeth are minute and the bite, of course, quite harmless. Their abundance is due to these qualities, not only, but even more to their great fecundity, 25 to 40 young in a season not being an uncommon product for one mother, and an instance of 80 is recorded. These are born alive, in early warm weather, and are able to care for themselves from the start, but the mother remains near them and protects them vigorously for some time. When cold weather approaches, these serpents seek underground retreats, such as old gopher-holes, and there often gather in large numbers which hibernate entwined together in a mass; mating takes place at this season. The skin is usually shed in the spring, by creeping through some crevice and scraping off the old hide, which peels backward from the head.

Of the score or more of species the greater number are Mexican and Central American; and some are known by very few specimens. The beautiful slender ribbon-snake (*E. saurita*) of the southern States is chocolate in color with three narrow distinct stripes, and has highly aquatic habits. The common species of the plains region (*E. radix*) is peculiar in its fondness for fish, catching them constantly in the pools and seizing every dead one cast on shore. A similar fish-loving species is the subtropical *E. macrostemma,* which appears in the talons of the eagle in the coat of arms of Mexico. The common species of California is *E. elegans.* In the southern part of that State occurs a rare form (*E. infernalis*), sometimes wholly black, save a yellowish throat. For the identification of the various species of this wholly American group the reader should consult Cope's 'Crocodilians, Lizards, and Snakes of North America,' published by the Smithsonian Institution in 1900.

Gary, Elbert H., American financier: b. Wheaton, Ill., 8 Oct. 1846. He was graduated at the law school of Chicago University in 1867; admitted to the bar of the Illinois supreme court the same year, and to that of the United States Supreme Court in 1878. He early applied himself to the practice of corporation law, and became general counsel for a large number of railroad and industrial corporations. It was largely through his legal work that his talents as an organizer of large industries first came into recognition. He retired from law practice in 1898 to become president of the Federal Steel Company, which in 1901 was merged into the United States Steel Corporation, he then being chosen chairman of its finance committee.

Gary, James Albert, American statesman: b. Uncasville, Conn., 22 Oct. 1833. He was educated at Allegheny College, Meadville, Pa. In 1861 he became a member of the manufacturing firm of James S. Gary & Son, and in 1870 succeeded his father as head partner. He was defeated as Republican candidate for governor of Maryland in 1879; and was postmaster-general in 1897–8, when he resigned.

Gas. See Critical Point of Temperature; Gases, General Properties of; Gases, Kinetic Theory of; Gasometric Analysis.

Gas and Gas Making. Illuminating gas, generally speaking, is the aeriform product of the destructive distillation of a liquid or solid hydrocarbon, in some instances diluted by the admixture of other combustible gas or gases. Practically all the illuminating gas manufactured throughout the world is made from bituminous coal, or petroleum, or some of the products of

the fractional distillation of petroleum. The gas made from petroleum or its products, and known as oil gas, has a very high candle-power value, and is generally mixed in the process of manufacture with hydrogen and carbonic oxide gases. The mixture is known as water gas. Upon the relative amount of hydrocarbon gas in the mixture will depend the candle-power of the final product. Gas made from bituminous coal is known as coal gas.

In the early days of the industry practically all the gas produced was from bituminous coal, but experiments were made with wood, rosin, and tar, all of them capable of producing illuminating gas, but not as satisfactorily or as economically as coal. The original works at Baltimore were constructed to make tar gas, but the attempt was a total failure, both in convenience to the consumer and profit to the manufacturer. In New York the first attempt was with oil gas, but as this was found too expensive, rosin was substituted, but subsequently abandoned, and coal used. In the Southern States pine wood and rosin have been used. When gas was first introduced its use was confined to shops and factories, a feeling being prevalent in the minds of owners of houses that it was dangerous, and productive of fires. Several delegations of citizens passed resolutions and signed memorials to various legislative bodies protesting against its use.

Water gas was first produced commercially by a Frenchman, Tessie du Motay, about the year 1865. About the same time an American, Prof. T. S. C. Lowe, who had won fame as an aeronaut during the Civil War, was experimenting in the manufacture of gas by the dissociation of steam in contact with incandescent carbon. The result of the operations of du Motay and Lowe was the development of the water gas systems which bear their names — the cupola-retort system of du Motay and the generator-superheater system of Lowe. These are the most important of all the inventions affecting the manufacture of gas up to this date. The experiments of du Motay as well as of Lowe were carried on in the United States, and the development of the water gas system is entirely American.

In all the processes of the du Motay type, the non-luminous gas is generated in cupolas, mixed with oil vapor, and passed through externally heated retorts, for the purpose of gasifying the oil vapor. The gases thereafter being condensed and purified, as are coal gas and water gas produced by other methods. The Lowe process, covered by patents dated 1872 and 1875, may be regarded as the basis of the modern water gas system. It covers, broadly, the use, in connection with a generator, in which non-luminous gas is made, of a superheater, or oil gasifying chamber, fired by internal combustion, the combustible being the carbonic oxide gas formed during the process of "blowing up" — that is, during and from the passage of air through the fuel in the generator. This air is blown through the fuel, hard coal or coke, at a high velocity, for the purpose of raising the fuel to a condition of incandescence fitting it to dissociate the steam admitted during the gas making period. The Lowe process further covers the introduction of oil, or other hydro-carbons, into the non-luminous gas, and the gasifying of the oil by passing through the previously heated superheater.

In the manufacture of gas from bituminous coal there are produced the so-called by-products, coke, tar and ammoniacal liquor, each of which finds a market, either in the raw state or worked up into other products for use in the various arts and manufactures. In the manufacture of so-called water gas, there is but one by-product, and that of minor importance, known as "Water Gas Tar." Its quantity and value depend in part on the kind of oil used in the manufacture of the gas, and in part on the care and intelligence with which the gas generating apparatus is operated. The tar contained in either coal gas or water gas exists in the form of a mist of small drops and vesicles, and is removed, in part by cooling and in part by rubbing against rough surfaces, or impinging against plates. This process is known as "condensation." The tar removed from 1,000 feet of coal gas is approximately one and one quarter gallons; the amount removed from a 1,000 feet of water gas varies between wide limits. It may be as much as one gallon. It is generally much less. The amount of ammonia that may be recovered from 1,000 feet of coal gas is approximately one half pound of ammonia gas.

Illuminating gas, whether made from coal or petroleum, contains certain impurities which must be removed before the gas is fit for consumption, or before it can yield the highest possible candle-power per foot of gas burned. These impurities are ammonia, which is present in coal gas, and sulphur compounds, which are present in both coal and water gas. Carbonic acid is also present in unpurified coal and water gas. It is of little importance, having no deleterious effect, beyond slightly reducing the illuminating value of the gas. It may be removed from the gas or its effect on the illuminating value compensated by the use of an enriching material, or it may be ignored. Ammonia is removed by bringing the gas into intimate contact with water, the water being applied either by a spray or a wetted surface of some so called scrubbing material, which may be coke, brush, thin rough sawn boards or other material having a large surface per cubic foot of space occupied. The amount of water required per unit of ammonia removed depends upon the temperature of the water and the intimacy of the contact between the water and the gas.

Various forms of apparatus for the removal of the ammonia gas are in use, but all depend upon the principle that cold water absorbs many times its volume of ammonia gas. The process of removing the ammonia is called "scrubbing." In the process of purification from sulphur compounds, slaked lime may be used. It is placed on wooden grids in a closed box, the gas being permitted to enter from the bottom and pass upward through the lime. Through the affinity of slaked lime for sulphuretted hydrogen this impurity is removed, and the sulphide of lime so formed has power of combining with other of the sulphur compounds in the gas. The slaked lime also removes whatever carbonic acid may be in the gas. The more general practice is to remove sulphur compounds by the use of iron oxide mixed with small shavings, or planer chips, and exposed to the gas in the manner described above in referring to purifi-

cation by lime. The active purifying agent in this mixture, which is called "iron sponge" or "iron mass," is hydrated ferric oxide of iron — $Fe_2O_3, 3H_2O$. It possesses the property of combining with sulphuretted hydrogen, but has no affinity for other sulphur compounds. After it has been a time in use, however, it contains considerable free sulphur, which has the power of arresting some sulphur compounds other than sulphuretted hydrogen. An advantage in the use of "iron sponge" for purification is, that after it has removed from the gas all the sulphuretted hydrogen which it is capable of absorbing, it will, upon exposure to the atmosphere, absorb oxygen, giving up the sulphur, which remains in the mass as finely divided sulphur mixed through the iron sponge. The mass, having been thus thoroughly re-oxidized by this exposure, may be used again, and so repeatedly, until the amount of free sulphur in it is equal to from 40 to 50 per cent of the whole material. It is then of no further value for gas purification, but because of the large quantity of sulphur and because of its containing a considerable percentage of the ferro-cyanides, it finds a market with manufacturers of sulphuric-acid and other chemicals.

Lime, after use in purifying gas, is of no further value and must be removed from the works or used as filling. This process of removing sulphur compounds is called "purification." When gas has been purified as above, it is passed through a large meter known as the "station meter," and thence into a storage holder, and is ready for distribution.

The first step in the manufacture of coal gas is to subject the coal to a high temperature. The coal is placed (technically called "charging") in retorts which may be made of fire-clay or of iron, but are almost universally of fire-clay, and closed, except as to one outlet for the gas. From this outlet the gas passes through what are known as stand-pipes to what is known as a hydraulic main, where the gas from all the retorts mixes, passing thence to the condensing and purifying apparatus. The temperature to which the coal is subjected varies, but it is generally recognized that it is economical to have this temperature as high as is consistent with maintaining the integrity of the retorts and the enclosing furnaces. The retorts are supported by means of blocks of fire-clay in a structure technically called a "bench," and heated by means of a fire, ordinarily of coke, built in a furnace below the retorts. In modern practice the retorts are heated to what might be called a bright cherry red, and about four hours are required to drive the gas from the coal. When the gas has been driven from the coal, the remaining coke is drawn from the retorts on to the floor, or into some form of conveying machinery, collected, and removed to the yard for storage and sale, except that enough is drawn from the retorts directly into the furnaces to supply fuel for the distillation of the coal.

The construction of retorts and enclosing furnaces, with the pipe connections from the retorts to the hydraulic main, is shown, in elevation and in vertical section, in Figures 1 and 2.

Figure 1 is an elevation of what is technically known as a "bench of fives" — that is, a furnace containing five retorts. AA are the retorts, which are ordinarily D shape in vertical section, 9 feet in length and approximately 26 inches in width, and approximately 16 inches in height. Attached to the front end of each retort is a so-called "mouth-piece" which is closed gas-tight by a lid. It is cast iron.

Attached to the mouth-piece is a so-called "stand-pipe," B, which conducts the gas, as generated, from the retort into the "hydraulic main," C. This hydraulic main extends the entire length of the "stack," which is the name applied to a number of benches built adjacent to each other and within one brick structure.

The process of operation is as follows: A fire is kindled in the furnace D, Figure 2, and the products of combustion, arising from the fuel, pass around the retorts, heating them to a bright cherry red. When this temperature has been reached, coal is thrown into the retorts, the charge varying in weight with the size of the retort. A large retort may take a charge of 350 pounds. The coal having been thrown into the retort, the lid is closed. The heat destructively distills the coal and the gas so produced passes out through the mouth-piece and stand-pipe into the hydraulic main. It will be seen, from the arrangement of the hydraulic main, that the gas passing from the stand-pipe bubbles through the water in the hydraulic main, the presence of the water preventing the return of the gas when the lid is again opened to draw out the coke resulting from the distillation of the coal, and to throw in a new charge.

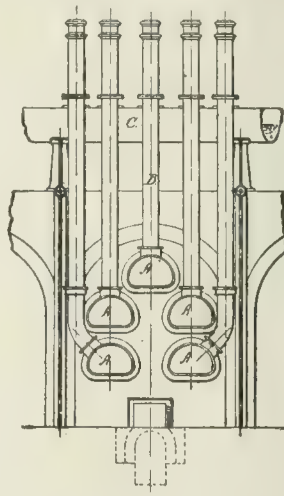


Fig. 1.

There are many forms of retort settings. In the more modern type the retorts are heated from what are known as regenerative furnaces, that is, furnaces which are worked at a comparatively low temperature and whose products of combustion contain a certain proportion of hydrogen and carbonic oxide, due to the introduction of steam below the fuel bed. These products, passing through ports to the chamber containing the retorts, meet there an incoming stream of air, which has been previously heated in flues, brought to a high temperature by the passage of the escaping chimney gases, through similar flues, parallel to and separated by a thin wall from the air flues. The furnace gases and the air combining in the retort chamber pro-

duce a very high temperature. The cuts illustrate the simpler form of retort setting and are given as being typical and easily understood, and not as showing modern practice.

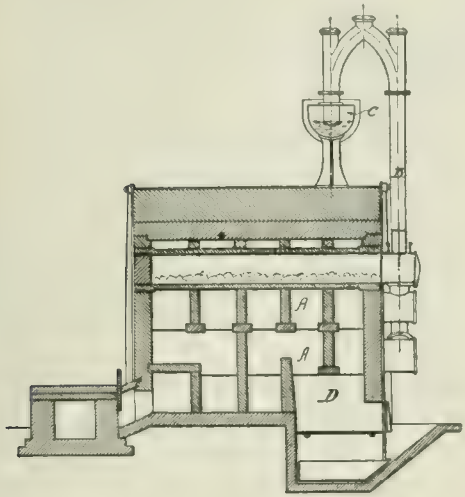

Fig. 2.

From the retort the gas passes to an exhauster, which is a form of gas pump, designed to draw the gas away from the retorts, and force it through the condensers, scrubbers and other apparatus and into the holder, thus reducing the gas pressure that would otherwise exist in the retorts. The operation of one type of exhauster will be readily understood from a reference to Figure 3, which is a cross-section of an exhauster.

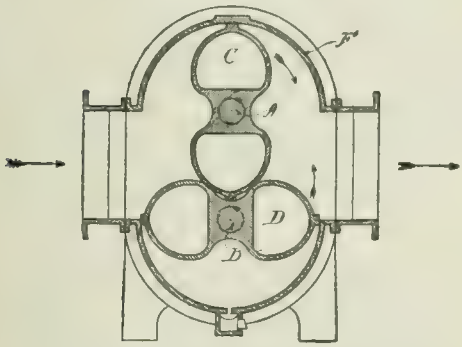

Fig. 3.

F is a cast-iron case, consisting of two half cylinders, of equal diameter, separated by a rectangular prism, and with flat ends. The moving parts consist of two impellers, C and D, keyed to the shafts, A and B, and so set in the case that the axes of the corresponding shaft, impeller and half cylinder, coincide. The impellers are so shaped that as they rotate each is always in contact, at some point, with the cylindrical portions of the case, and at the same time in contact with the other impeller, while the ends are practically in contact with the ends of the case. The shafts are supported by bearings on the case, and connected with each other at each end by two gear wheels, one on each shaft, of the same diameter and with an equal number of teeth, so that the relative position of the impellers is always the same at the same point in any revolution. The lower shaft is extended at one end and provided with a belt pulley, or connected direct to an engine on the same bedplate as the exhauster.

The action is as follows: Motion being imparted to shaft B, is transmitted through the gear wheels to shaft A, causing the two impellers to rotate, as shown by the arrows, and by the continual increase in volume of the space on the inlet side and decrease in volume of that on the outlet side, to draw the gas from the inlet and force it through the outlet, the contact between the impellers preventing the gas from passing back between them. From the exhauster the gas goes to the "condenser," a device designed for the cooling of the gas and the removal of the tar.

A simple form of condenser is shown in Figure 4. It consists of a nest of wrought-iron

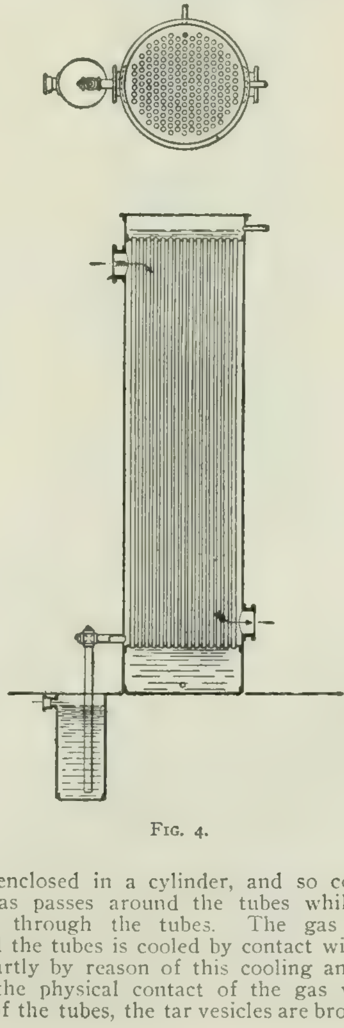

Fig. 4.

pipes enclosed in a cylinder, and so connected that gas passes around the tubes while water passes through the tubes. The gas passing around the tubes is cooled by contact with them, and partly by reason of this cooling and partly from the physical contact of the gas with the sides of the tubes, the tar vesicles are broken, and

combining into drops, run down as drops of tar to the lower part of the cylinder, from which the tar is conducted, through an appropriate pipe, to the well or reservoir, as shown. The gas goes next to the "scrubber," which is designed for the removal of ammonia.

A simple type of scrubber consists of a wrought-iron cylinder, filled with wooden grids, coke or other porous material. Figure 5 shows

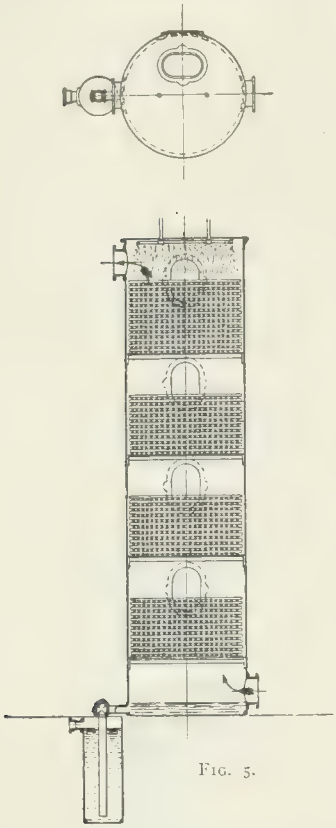

FIG. 5.

a scrubber with grids. The gas entering at the bottom passes up through the filling against a shower of water dripping over the filling. The intimate contact of the gas and water results in the absorption of the ammonia from the gas and also the removal of a certain part of the sulphur compounds and carbonic acid present in the gas, in combination with the ammonia — as sulphide of ammonia and carbonate of ammonia. The scrubber will also remove any traces of the tar that may have escaped from the condensing apparatus.

There are several forms of scrubbers. The above described is the simplest, and except that in some of them the scrubbing material is mechanically moved, so as to come alternately in contact with the water and the gas, the principle of all is substantially the same.

The gas passes from the scrubbers into the purifiers. These are rectangular boxes that are ordinarily built from 3 to 8 feet deep, and of a horizontal section depending upon the amount of gas that it is desired to purify in them. They are ordinarily built in sets of four or six, so connected by pipes and valves that the stream of gas may be made to flow through them in any order desired,— this because it is found economical to pass in sequence through the purifiers and to be able to vary this sequence as the material in the different boxes is more or less charged with sulphur compounds. A section and plan of a box are shown in Figure 6. A is the

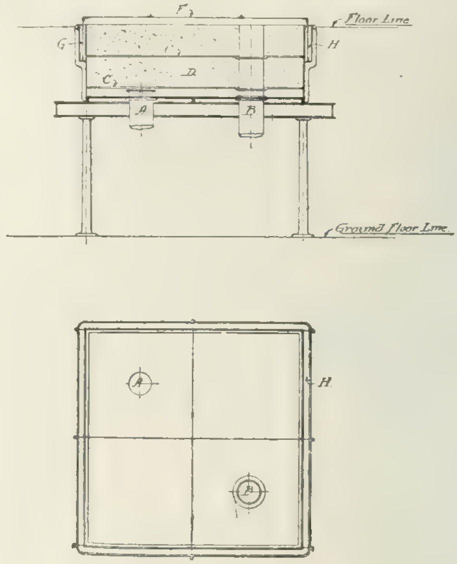

FIG. 6.

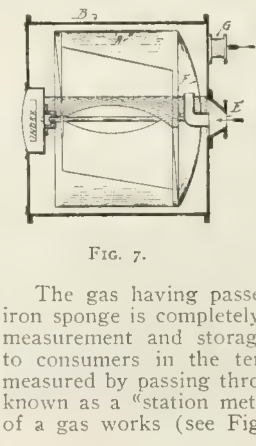
gas inlet at the bottom of the box. B is the gas outlet. C are the trays upon which the purifying material D, either lime or iron sponge is placed. F is the lid which is made gas-tight by the insertion of the lip G on its edges into the water-seal H, bolted to and encircling the box. When the lid is on the box the lip G, being in water, will prevent the flow of gas from the box into the atmosphere. When the purifying capacity of the material in the box has become exhausted, which is determined by appropriate tests, the gas is shut off from that box, the lid is raised, and the material is removed — to be carted away, if it is lime, or to be spread upon a brick or concrete floor, for re-oxidizing, if it is iron sponge.



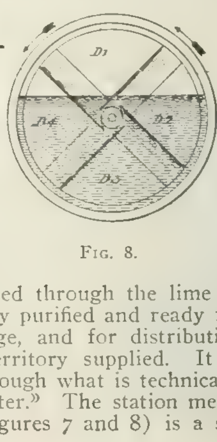


FIG. 7. FIG. 8.

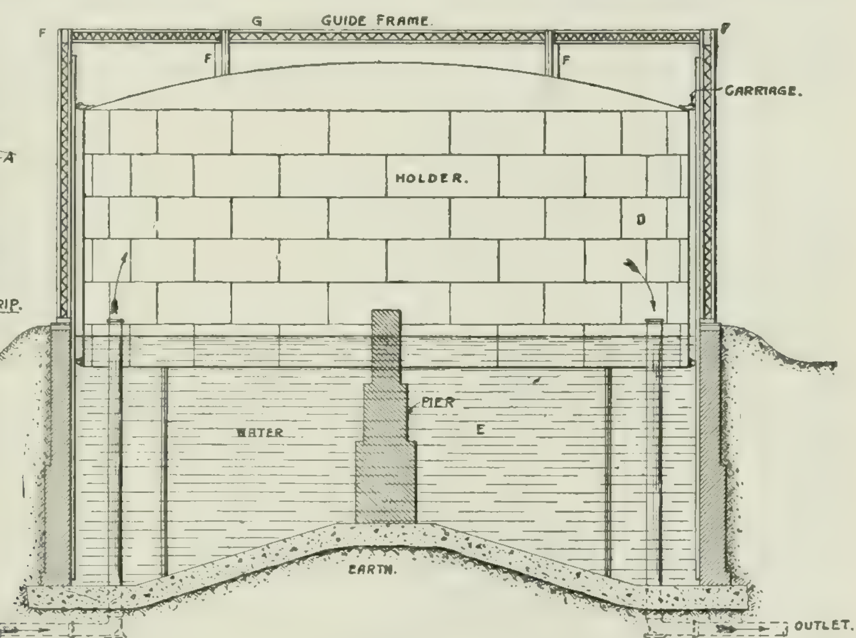
The gas having passed through the lime or iron sponge is completely purified and ready for measurement and storage, and for distribution to consumers in the territory supplied. It is measured by passing through what is technically known as a "station meter." The station meter of a gas works (see Figures 7 and 8) is a so-

called "wet" meter of large dimensions. In principle it is the same as the small wet meters used for measuring gas as sold to individual consumers in those cities whose winter temperature is above the freezing point of water. Figures 7 and 8 show vertical sections of a station meter. It consists essentially of a drum or cylinder of metal, A, horizontally mounted in a metal case, B, so that it may revolve freely on its axis, and divided by wings or partitions into several compartments, D1 to D4, the shape and position of the wings being so designed that, as the drum revolves, each end of each of the compartments so formed, in turn opens above the surface of the water in which the drum revolves, and which fills the enclosing case to about three fifths of its diameter, no compartment having both its inlet and outlet ends above the surface of the water at the same moment. The gas to be measured is introduced through a pipe, E, entering one end of the meter case and compartments filled and emptied is the amount of gas that passes through the meter. This is registered on a dial connected to the drum through an appropriate series of gear wheels. The meter drum revolves because the gas entering is forced by the exhauster into the space between the outer surface and the inclined side of the compartment opening at the moment above the water.

The point of view of Figure 8 is the inlet end of the meter. The drum revolves in the direction of the arrows. Compartment D4, as shown, has its inlet submerged and its outlet open, and as the meter revolves the water enters this compartment, expelling the gas, which flows out of the drum and through the space between the drum and the case to the meter outlet, G. Compartment D1 is full of gas with both inlet and outlet submerged, the outlet being about to rise above the water. This will happen before D4 is entirely emptied of gas. D2 is filling with gas,

CUP AND GRIP.

FIG. 10.



SECTION.

FIG. 9.

rising to above the water line through a hood, F, covering the inlet end of the drum. Into this hood open the inlet ends of the compartments of the drum. As the drum revolves, the inlet end of each compartment in turn rises above the water and receives gas through the inlet pipe and hood. Because the other end of the compartment receiving gas is below the surface of the water, no gas passes through, but all that enters is retained in the compartment until its inlet end is again sealed by passing into the water. At that moment its outlet end rises above the surface, and the water, entering the inlet end as the revolving drum carries the inlet down, forces the gas through the outlet end of the compartment. As one compartment empties, another is filling, and the flow through the meter is continuous, though intermittent as to any compartment. The sum of the contents of the its inlet being above and its outlet below the surface. It is the force of the gas entering this compartment that is giving motion to the meter drum, and expelling the gas from the compartment D4. Compartment D3 is entirely filled with water. It will begin to receive gas before D2 is quite full and while D1 is emptying.

From the station meter the gas passes to the holder or holders, in which it is stored for use at such hours as the demand in the district supplied is in excess of the capacity of the manufacturing apparatus.

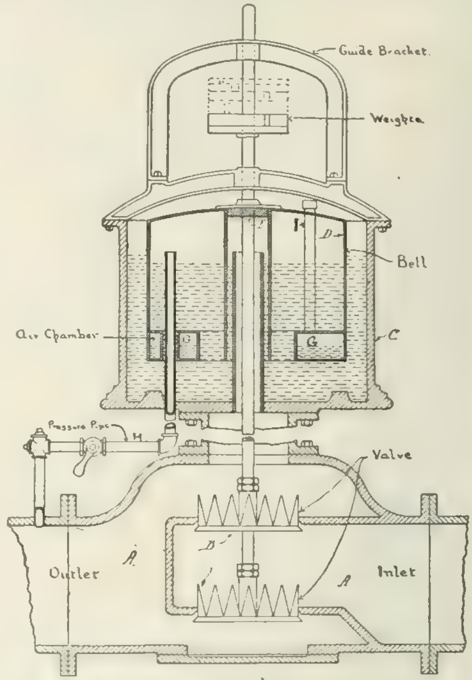
The construction and action of a gas holder, sometimes erroneously called a "gasometer," may be readily understood by reference to Figure 9.

A gas holder consists of a sheet iron cylindrical vessel, D, closed at the top, open at the bottom and floating in a tank, generally built of brick, as in the figure, or of iron, open at the

top and filled with water. The holder is so guided in the tank and along columns FF, standing on the edge of the tank, and connected at the top by girders, that it will rise and fall freely as gas is forced into it or permitted to pass out. The columns and girders are called the "guide frame." To reduce to a minimum the friction produced by the rising and falling of the holder, rollers are attached to its upper and lower circumference. These rollers move on plates inserted into the tank for the purpose, and against the columns above referred to. Gas is admitted to the holder through what is known as the inlet pipe, A, rising above the water in the tank, and opening under the holder. As gas is forced through this pipe into the space between the water and the holder it forces the latter to rise. Gas passes from the holder to the street mains through the outlet pipe, B. As ordinarily used, gas flows continuously into and out of the holder, or set of holders, the excess of make of gas during the day filling them in preparation for the increased demand during the dark hours.

Large gas holders are often made of a so-called "telescopic" type. This expression means that there are within the tank several concentric cylindrical wrought iron sections, one of which only is closed at the top — this being the inner section. The columns in this case have a height equal to the sum of the heights of all the sections. The inner or covered section has as its lower edge a circular trough or "cup" A (Figure 10) which, as the section rises, engages with a similar but inverted trough B, called a "grip," on the upper circumference of the next section. The trough on the lower edge of the inner section being filled with water, a water seal is formed, which prevents the escape of gas. When the holder is down, the cups and grips are under water. Each section, in turn, as it fills with gas, and its lower edge rises to the surface of the water, engages the next lower section in a similar manner. When all the sections are full of gas the volume contained is approximately the capacity of a single section holder multiplied by the number of sections. The main advantage of the system is the small tank depth and ground area per unit of volume of holder capacity. As the gas flows out from the full holder, and the holder sinks into the tank, each section in turn rests on landing stones in the bottom of the tank. The inner section is not permitted to sink so far as to touch the landing stones, but is kept always afloat, except when necessary to make repairs.

The gas leaving the holder to enter the distributing system passes through a district governor, Figure 11. This is a device for establishing and maintaining, at the will of the operator, any desired pressure of gas at the point where the gas enters the street main system. It consists essentially of a valve box, A, inserted in the pipe leading from the holder to the street mains, and containing a valve, B; a cast iron tank, C, placed over the valve box; a sheet iron bell, D, working in the tank, and so fastened to the valve rod, E, that as it rises and falls the valve moves with it, and a connection, H, called the pressure pipe, from the outlet of the valve box to the interior of this bell. The shape of the valve is not important. It may be conical, parabolical or cylindrical, but it must always be so made and so arranged that the upward and downward pressures exerted upon it by the gas will be equal, and so balance each other. In the cut it will be seen that two surfaces of the valve are exposed to the inlet pres-



Non-Automatic Street Main Governor.
Fig. 11.

sure,— one a lower surface and the other an upper surface. Also that two surfaces of the valves are exposed to the outlet pressure,— one a lower surface and the other an upper surface. The pressure on the lower and upper surfaces, it will be seen, balance each other; therefore, they will have no effect on the position of the valve or the bell. There is an annular air chamber, G, on the bell, D, and located beneath the surface of the water in which the bell floats. It is designed to counterbalance the weight of the bell. The exact balance desired is established by pouring water into the air space through the pipe I, rising above the top of the bell. The interior of the bell is connected with the outlet of the governor, through the pressure pipe, H. When, because of an increased consumption of gas along the lines of mains, the pressure on the mains is reduced, the pressure on the interior of the bell is also reduced. This will cause the bell to drop until the opening in the valve connected to the bell is sufficient to pass enough gas to restore the pressure in the outlet, and, therefore, under the bell, which existed before the increased demand for gas occurred. In like manner, if the demand for gas upon the mains is reduced, the pressure in the mains will rise, which also raises the pressure on the interior of the bell — closing the valve until the opening is only sufficient to allow enough gas to pass to maintain the pressure previously existing in the outlet and under the bell. In order to increase the pressure in the outlet, which is important at hours of increased demand for gas, it is sufficient to place weights on the top of the bell, as

shown in the cut. This addition of weight makes a higher pressure necessary at the outlet for any given position of the bell, and, therefore, for any given opening in the valve. To reduce the pressure at the outlet, weights are removed from the bell. It will be seen that it is thus a simple matter to regulate the pressure at the outlet of the governor, and therefore, in the inlet of the street main system, from hour to hour, as the demand for gas varies. It will be impossible with this device to increase the pressure at the outlet of the governor beyond the pressure at the inlet of the governor.

There are governors in use that automatically establish and maintain predetermined pressures in the main system. They are in principle as the governor described, except that by means of an ingenious device they automatically increase or diminish the weight on the bell as the pressure at the governor outlet diminishes or increases.

The sequence of the apparatus above described, and the part each takes in the preparation of coal gas for illuminating purposes, is graphically shown in Figure 12 which represents, in brief, the essential parts of a coal gas apparatus from the retort to the governor, and supposed to be in operation. All auxiliary apparatus, boilers, engines, pumps, conveyors, etc., are omitted from the sketch.

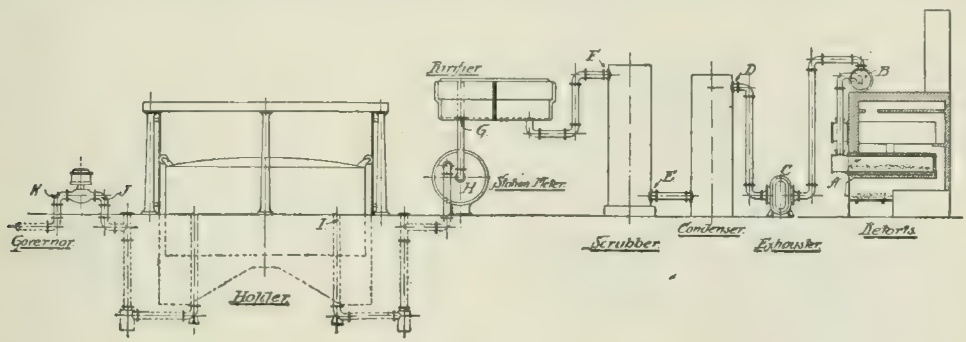


Fig. 12.

At A is the coal being distilled. At B the gas rising from the coal is bubbling through the water in the hydraulic main. At this point the gas contains all the tar and impurities with which it leaves the coal. It is a dark brown color and so dense as to be opaque. Its temperature is approximately 200° F. It consists of hydro-carbon gases, hydrogen, carbonic oxide, water vapor, ammonia, sulphuretted hydrogen and other sulphur compounds, carbonic acid, tar — as a mist of vesicles and small drops,— free carbon and traces of nitrogen and oxygen. At C is the exhauster pumping the gas from the retorts and forcing it through the subsequent apparatus into the holder. At D the gas entering the condenser is practically as it entered the hydraulic main, except that a proportion of the tar and water vapor and all the free carbon have been deposited, due to the cooling of the gas and friction. At E the gas entering the scrubber has parted with practically all of the tar and most of the water vapor it contained when leaving the retort, and with the water vapor there has been deposited a certain amount of ammonia, which the water vapor absorbed as it condensed to liquid. The ammonia absorbed by the water also carried out of the gas a certain part of the carbonic acid and sulphur compounds. At F, the outlet of the scrubber, the gas has practically lost all of its ammonia, water vapor and tar. It is now transparent, and contains of deleterious constituents only sulphur compounds. At G, the outlet of the purifiers, the sulphur compounds have been removed to an extent that renders the gas fit for consumption in closed rooms. The gas may now be used without fear of injury to person or fabrics. At H the gas is passing through the station meter. At I the gas is entering the holder, where it is stored, to be used as the demand of the town or district supplied may require. At J the gas is entering the governor. At this point the pressure will vary and have no relation whatever to the requirements of the district supplied. At K the gas is leaving the governor. At this point the pressure of the gas may be varied in accordance with the demands of the district supplied. If, owing to the approach of evening, or other causes, the consumption of the gas in the town or district increases, the governor, if automatic, will open, thus providing a passage for a larger supply of gas and increasing the pressure at the outlet of the governor. If the governor is not automatic in its action, the pressure may be varied by the addition or subtraction of weights as heretofore described.

The generation and preparation of water gas differs radically from coal gas manufacture, up to the point of entrance to the purifiers; thereafter there is no material difference in the treatment of the two gases.

Figure 13 represents in brief the essential parts of a water gas apparatus, from the generator to the purifier. All auxiliary apparatus, boilers, engines, blowers, etc., are omitted from the sketch.

The Lowe Double Superheater Water Gas Apparatus, which is the modern type of apparatus for the generation of what is known as carburetted water gas, consists essentially of three wrought-iron cylinders connected in sequence, the top of the first cylinder or generator being connected to the top of the second cylinder, or carburetter, which is at its bottom, connected with the bottom of the third cylinder or superheater. The connections in practice are short and like the cylinders lined with fire-brick.

In Figure 13, A is the generator, B the carburetter, and C the superheater. A, B and C are connected with a main blast pipe H and so arranged that air may be introduced in desired quantity and proportion to beneath the grate in A, to the top of B, and to the bottom of C. At the top of C is a stack valve (7) for the exit of the waste furnace gases, and a take-off pipe (8) for the exit of the water gas. When the apparatus is in operation A is filled nearly to its outlet with coke or anthracite coal. B is filled to within a short distance of the connection with A with so-called "checker brick," or fire-brick placed on edge, and with openings between them of from one and one half to three inches. C is similarly filled with fire-brick to within a short distance of its outlet. The fire-brick in B and C are supported on fire tile arches a short distance above the connection from B to C.

The process of making gas in this apparatus may be conveniently divided into two periods, called, respectively, the "blow" and the "run." The blow is the period of introduction of air to gases still contain a small proportion of the unconsumed carbonic oxide and hydrogen, which burn in the air introduced at this point through valve (3) heating the checker work in C to the temperature desired. During the blow the "stack" valve (7) is open and the products pass out of the chimney and so into the open air. When the apparatus has been brought to the desired temperature, which is known from observation through sight cocks conveniently placed, the air is shut off from the three chambers A, B and C, and steam is admitted under the fuel bed A. Oil is then admitted into the top of the chamber, B, spraying down over the checker work in B, and mingling with the carbonic oxide and hydrogen gases formed by the passage of the steam through the fuel in A. The oil is vaporized immediately upon contact with the bricks in the hot chamber, B, and the vapor passing with the gases down through the hot checker brick of B, and up through the hot checker brick of C, is gasified, and the mixture of gases passes out through the outlet valve at the top of C, as carburetted water gas. The

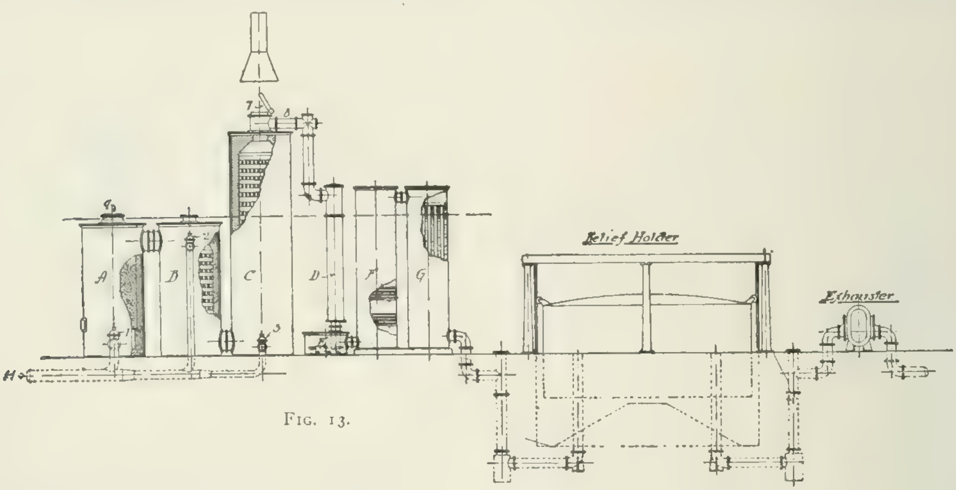

Fig. 13.

the apparatus in the process of heating it to a temperature at which it can economically treat the steam and oil used in the manufacture of the gas. The run is the period of the introduction of steam and oil, and therefore of the generation of gas. Necessarily the blow precedes the run. A power blower maintains a pressure of air on the blast pipe to which are connected the blast valves leading to the apparatus as above described. The valve (1) being opened, air flows into the generator A beneath the grate. Being under pressure this air rises through the fire bed, bringing it to a high state of incandescence. The products of combustion leaving the fuel bed are nitrogen and carbonic acid, with a relatively small proportion of carbonic oxide and hydrogen. Passing into the top of the carburetter B these gases meet an incoming stream of air, admitted through the valve 2, in which the carbonic oxide and hydrogen in part burn to carbonic acid and water vapor. This combustion raises the temperature of the gases and of the checker brick in B down through which the gases pass to the outlet of B and into the bottom of the superheater, C. At this point the stack valve (7) is closed at the moment that the carburetted gas appears, which marks the expulsion of all the blast gases previously contained in the apparatus. Upon the closing of the stack valve the carburetted water gas makes its exit through the outlet pipe D to the wash box E. At this point the gas is brown in color and opaque; it is composed of hydro-carbon gases, hydrogen, carbonic acid, carbonic oxide, sulphur compounds, tar, water vapor, free carbon, nitrogen and oxygen. In E, which has the function of the hydraulic main in coal gas generation, the gas deposits a considerable amount of the tar and free carbon, or lamp black, which it contained and which are due to the gasifying of the oil. From the wash box E the gas passes through the scrubber, F, which in design is similar to the scrubber described above in connection with coal gas manufacture. The scrubber F removes the lamp black and a large proportion of the tar from the gas. These are washed down through the trays in F by a spray of water admitted at the top. The gas passing through the condenser G is cooled to the temperature desired. The last traces of tar may here be removed.

The run is continued until the temperature of the apparatus falls to a point that makes it necessary to re-heat the brick work and the fuel bed. When this temperature has been reached, the oil and steam are shut off. The air valve (1) is opened. The blast rising through the fuel bed in A forces ahead of it the good gas contained in B and C until the judgment of the operator tells him that all the good gas has been forced out of the cylinders, at which moment he opens the stack valve (7).

It will be noted from the above description that the scrubber is before the condenser, which is the reverse of the order in coal gas manufacture. The reason of this is that in water gas manufacture there may be a certain amount of lamp black in the crude gas which must be washed out at the earliest possible moment, and also because there is no necessity of cooling water gas before scrubbing, because there is no ammonia to be removed. The gas leaving the condenser passes to a gas holder, known as a "relief holder," used to equalize the flow of gas to the purifiers, making it uniform from minute to minute, although the process of water gas generation is intermittent, as above described.

From the relief holder the gas is drawn by an exhauster located at the inlet to the purifiers, and from that point on its preparation for use is the same as described above in coal gas manufacture.

After purification, measurement, and storage, the gas, whether coal or water gas, enters the "distribution system," through the governor heretofore described.

The gas leaving the governor enters the street main system. The size of the pipes in this system and their distribution in the streets of the districts supplied depend upon the amount of gas to be delivered in the period of maximum demand, and upon the location, in the district supplied, of the areas of large and small consumption at the time of maximum delivery. The main pipes are ordinarily of 12-foot cast iron lengths, jointed with lead or cement. Wrought iron mains are in use to a considerable extent in some cities.

A "service" is the technical name applied to a pipe laid from the main to supply an individual consumer, the distinction between a main and service pipe being that the main pipe is laid for the general supply of a district or street,—a service pipe being used to connect this main with the premises of a consumer.

A certain amount of water vapor condenses in the mains and services of a gas distribution system, and it is necessary that these should be so laid as to drain to some central point or points, at which this water can be collected in so-called "drips," and the stoppage of mains and services by this accumulated condensation prevented. These drips are cast iron pots, and are connected to the mains at low points in the distribution system. The condensation is pumped from them through a small pipe rising from the bottom of the drip to the surface of the ground, where it is plugged and covered with an iron cap. Observation soon indicates how frequently it is necessary to pump any drip, and at such times a wagon, fitted with a tank, a pump and a hose connection, is sent to the spot and the water is pumped from the drip into the tank on the wagon.

Services are almost universally of wrought iron. It is common practice to provide on a service, at or near the curb line of the street, a cock which may be opened with a wrench inserted through a cast iron box having a lid at

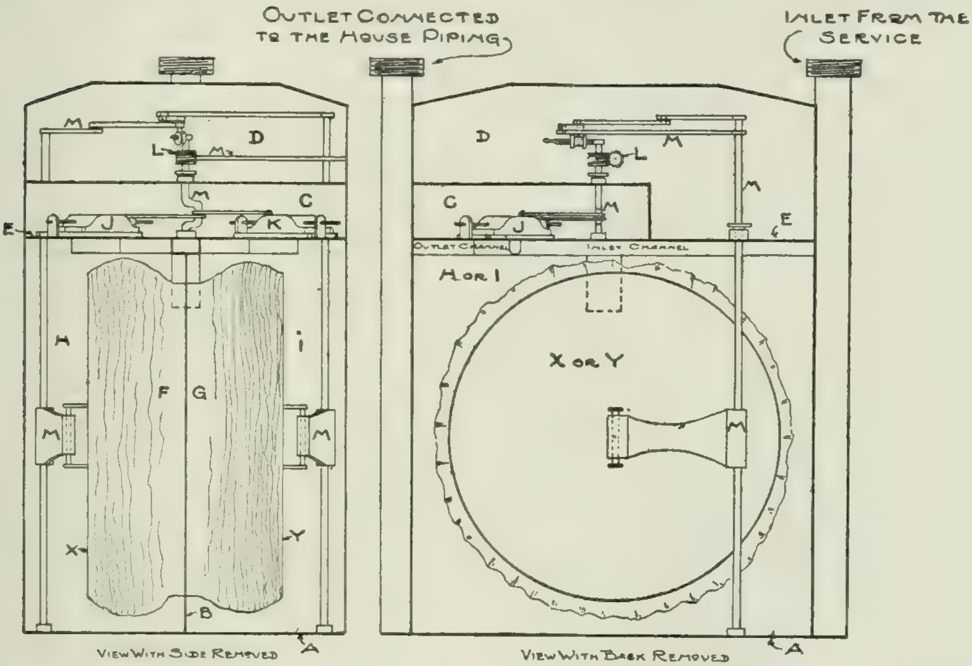

FIG. 14.

the surface of the sidewalk. The purpose of this is to enable the gas company to shut off the supply of gas from any premises in case of fire, or in case of the abandonment of the use of gas on the premises. The arguments for and against the practice of using so-called "service cocks" have persuaded some companies to adopt and some companies to reject them. The service pipe passes ordinarily through the cellar wall to a meter located in the cellar of the premises to be supplied.

The meter used in cold countries to measure the gas supplied to an individual consumer is almost universally of the "dry" type, which, as shown in Figure 14, consists of a tin box A divided into two measuring compartments by a vertical partition, B, these measuring compartments being separated from the superimposed valve and dial compartments, C and D, by a horizontal partition E. The measuring apparatus consists of two leather bellows, F and G, attached to the tin partition, B, and having light tin heads, X and Y, and located one in each of the measuring compartments H and I. The bellows are connected with the valves J and K and the dial gearing L through the rods and cranks M, M.

Gas is measured, as is any liquid commodity, by the alternate filling and emptying of enclosed spaces having a determinable and unvarying capacity. The capacity of the spaces multiplied by the sum of the fillings and emptyings is the volume measured. In the dry meter the gas is measured in the bellows F and G, and in the measuring spaces H and I, surrounding the bellows. Each bellows and each surrounding measuring space is alternately filled with gas, shut off for a moment from any connection with either the inlet or the outlet of the meter, and then opened to the outlet. This filling and emptying is so alternated that there is a continuous flow of gas through the meter, as long as there are any openings for the escape of gas in, or connected with, the house piping connected to the meter outlet. When no openings exist there is no place for the gas to escape and the meter will not move. To understand the action of the meter it is best to follow it through a complete cycle — see Figure 14. Assuming th burners to be all shut off and no leaks to exist in the house piping, the pressure on the outlet of the meter will be the same as on the inlet, no gas will pass, and as it is the passing of gas that moves the meter, it will, under the conditions assumed, be at rest.

In whatever position the bellows and connected valves of the meter may be, and whether the meter be in action or at rest, there is always an opening for the gas into one of the bellows or measuring spaces, and another opening from the other bellows or measuring space into the meter outlet and house piping. If now a burner cock be opened, the gas in the house pipes will begin to flow out through the burner, the pressure in these pipes and in the bellows, or measuring space, at the moment open to the house piping, will fall, and the gas in the service will tend to flow in to restore the pressure. To do this the gas must pass into the meter. Assume that the inlet of bellows F is open. The valves and connections are so arranged that when this condition exists the outlet of F and the inlet of space H will be closed, and the outlet of space H will be open. The gas from the service will then, by reason of the reduced pressure in the house piping and in the space H, force its way into the bellows F, expanding it into the space H, and forcing the gas from the space H through its outlet valve into the meter outlet and the house piping. When the bellows F has expanded to its full working length the rods and cranks connecting it to the valve J will have so far moved the latter that the inlet to the bellows F will close and its outlet open. This change also closes the outlet of space H and opens its inlet. Gas now flows into H, compressing the bellows F, and forcing the gas from it into the house piping. It is clear that at each filling of the bellows F there will be displaced from H and forced into the house piping as much gas as enters F; and that at each emptying of F an equal volume of gas enters H. Thus we have H and F alternately filling and emptying as long as the burner cock is open. It is evident that the gas does not flow through the bellows or through the measuring space. It flows into them alternately, is for a moment shut in, and then as the outlet valve opens flows out. There is, therefore, a definite measuring of each volume of gas that passes the meter. This volume is indicated on the dial by the movement of the rods, cranks and gearing.

In order to insure a continuous flow of gas to the burner, with an intermitting motion to the bellows, each meter is composed of at least two bellows and measuring spaces, so valved that there shall be no moment when there is not at least one inlet and one outlet open. When the burner cock is closed the pressure in the house piping rises in a moment to that in the service and the meter ceases to move. It is evident that when gas is passing the meter it is because the pressure in the service is enough in excess of the pressure in the house piping to overcome the inertia and friction of the moving parts of the meter; and, further, that the meter must cease to move the moment these pressures are equalized. As this difference cannot continue if there is no outlet for the gas, no gas can pass unless an opening exist in the house piping.

Meters are tested for accuracy by passing through them a volume of gas accurately measured in a small gas holder. The law commonly recognizes as accurate a meter that is not more than 1½ per cent "fast" or 2 per cent "slow."

Pure oil gas and acetylene gas are, to some extent, used for illumination.

Oil gas is extensively used for car lighting It is ordinarily generated in retorts very similar to coal gas retorts — the oil being drippec into the retort from the end of a pipe. The gas, after purification, is compressed in cylinders, from which it is drawn into similar and smaller cylinders, located under the car to be lighted. Pure oil gas after compression has an illuminating power of approximately 50 candles.

Acetylene is one of the most interesting of illuminating gases. It is produced from carbide of calcium and water. Carbide of calcium, chemical formula — CaC_2, is produced by the fusion of carbon and quicklime in the heat of the electric arc. When water is poured upon this substance acetylene gas is liberated. The chemical reactions are as follows:

Calcic Carbide + water = Lime + Acetylene

$CaC_2 + H_2O = CaO + C_2H_2$.

When there is an excess of water present the following reaction also takes place:

$CaO + H_2O = Ca(HO)_2$

Quicklime + water = Slaked lime.

Acetylene has an illuminating power of approximately 240 candles. Coal gas has an illuminating power of 14 to 18 candles, and water gas as ordinarily supplied, has an illuminating power of 20 to 27 candles.

Gas produced by the distillation of coal for the production of coke, for industrial uses, has in recent years been conserved, and in some cases is being distributed by local gas companies. This gas is generated in large ovens, generally heated by the combustion of a part of the gas produced, and is treated in the same manner as coal gas generated in retorts, as heretofore described.

The «candle-power» of gas is the amount of light it yields, expressed in terms of standard sperm candles, made under rigid specifications and burning at the rate of 120 grains of sperm each per hour, the gas being consumed through a specified burner at the rate of 5 cubic feet per hour, and depending for its light on the incandescence of some of its component parts, and not, as in the case of the Welsbach burner, on the incandescence of some extraneous substance, subjected to the heat of the flame. Briefly, when it is said that certain water gas is of 25 candle-power, it means that when burned at the rate of 5 cubic feet per hour, through a suitable burner — it would yield 25 times as much light as would a standard sperm candle, made under specifications prepared by the Board of Trade of London, and burning at the rate of 120 grains of sperm per hour.

There are some gases, as for instance acetylene, which cannot be burned at as high a rate as 5 cubic feet per burner per hour without badly smoking. When it is said that acetylene gas is of 240 candle-power it means that when burned at an efficient rate it yields a candle-power that bears the same proportion to the rate at which it is burned as 240 bears to 5.

The calorific or heating value of a gas is the amount of heat generated by the combustion of one cubic foot of the gas, generally expressed in British thermal units. A British thermal unit is the amount of heat absorbed by one pound of water when raised 1° F. in temperature — the temperature being at or near the maximum density of water, or 39.1°. The heating power of gas varies. Acetylene gas has a calorific value of 1,477 heat units per cubic foot. That is to say, the combustion of one cubic foot of acetylene generates as much heat as it is necessary to add to 1,477 pounds of water to raise the temperature of the water from 39.1° to 40.1° F. Natural gas may have a value of approximately 1,000 heat units per cubic foot. Following are analyses of a water gas and a coal gas, giving the calorific value by calculation; that is, the theoretical heating value, as estimated from the heating value of the components of the gas. The value by calculation will be higher than the value developed in a test with the calorimeter, because of some slight losses in the use of the calorimeter.

Gas develops its highest illuminating effect when flowing from the burner at a low pressure. To accomplish this there is located in the burner, at some point below the tip, a so-called «check,» having an opening of less area than the opening in the tip at the point of combustion. Obviously, the gas flowing through the burner at any rate per hour, will pass through the outlet and larger opening at less pressure than is required to force it through the smaller opening in the check.

	Water gas	Coal gas

	100.0	100.0
Calorific value by calculation	669.5 Brit. Ther. Units.	647 B. T. U.

Burners for illumination, excluding the Welsbach and other forms of incandescent burners, are of three general types, the batwing, the fishtail and the argand. (See Gas Illumination, History of.)

Gas pressures are expressed in terms of height of water column. If we say the gas pressure is «one inch» we mean that it is equal to the pressure of a column of water one inch high. If we connect to a gas pipe one leg of a U-shaped glass tube, half full of water, the other leg being open to the atmosphere, the water will fall in one leg and rise in the other until the difference in the water levels in the two legs equal the pressure of gas in the connected pipe. If this difference is one inch we say the gas has a pressure of one inch.

The conception of a system of illumination comprehending a central source, and radiating lines of conduits; the measurement and recording of the service rendered as rendered, and the absolute and immediate control by the served of the time, period and measure of service, was as bold and startling as has occurred in the mind of man. Its fruit, the science and art of gas lighting, has amply justified the conception and has had a leading position among the activities of the wonderful 19th century. Wax and sperm oil were for 50 years its most potent competitors in the field of artificial illumination. Then came the discovery and the utilization of petroleum. Next, and so far last, came the wonderful and adaptable electric light.

Walton Clark,
Gen. Supt. the United Gas Improvement Co., Philadelphia.

Gas-engine is the commonly accepted term for all prime movers which derive their power from the combustion of a properly proportioned mixture of gaseous or liquid fuel and air directly in their cylinder. In the modern engine the combustion takes place after the explosive mixture has been compressed to a certain degree, either by the inward movement of the piston in the power-cylinder, or by the action of a separate compressor which forces the mixture into the working-cylinder in a compressed state. The «explosion» of the compressed charge is in reality a very rapid burning, creating a high degree of heat and a resulting expansive force which causes the piston to be driven forward with an initial or maximum pressure approximating 200 to 250 pounds, and a mean pressure of 80 to 100

pounds per square inch of piston-surface. The power thus generated is transmitted to the driving-pulley or fly-wheels by means of the connecting-rod and crank-shaft. All internal-combustion engines using as fuel hydrocarbons, such as the various kinds of artificial gas, natural gas, petroleum and its by-products (gasoline, benzine, naphtha, distillate), and more recently alcohol, may be classed under the general term of gas-engines.

Development of the Gas-engine.— An investigation of the history of the gas-engine discloses the fact that the idea of employing the expansive force of air and fuel directly in the working-cylinder of an engine suggested itself to the minds of inventors before the advent of the steam-engine. Motors using gunpowder as fuel were proposed by Huyghens in 1680, Hautefeuille in 1682, and Papin in 1688. In 1791 John Barber obtained an English patent on a gas-turbine, in which gas generated from solid or liquid fuels was to be mixed with air and water, and the mixture, after having been ignited, was to exert its force upon a turbine. Another English patent, granted to Robert Street in 1794, describes an oil-engine in which the fuel is evaporated in the cylinder and ignited by a flame after the piston has completed half of its outward stroke.

Lebon in 1801 took a French patent on a double-acting gas-engine, having two pumps for mixing and compressing air and illuminating gas into a reservoir, and from there forcing the mixture into a double-acting working-cylinder, where it was to be electrically ignited. English patents were granted on internal-combustion motors of various construction, and using different means of ignition, to Brown in 1823, Wright in 1833, William Barnett in 1838, Johnston in 1841, Drake in 1842, and Barsanti and Matteucci in 1854. In 1858 Degrand proposed the compression of the mixture in the working-cylinder, and not in separate pumps as before.

Some of the engines mentioned above were actually built, but none were put to commercial use. In 1860 Lenoir in Paris built and placed on the market a one horse-power, double-acting gas-engine having a cylinder three inches in diameter, with a piston-stroke of 5½ inches. This engine had an electric igniter placed in the cylinder-wall at a point opposite half the length of the cylinder, and the electric spark, which jumped constantly between two platinum points, was exposed to the inside of the cylinder alternately on both sides of the piston by the forward and backward movements of the piston itself. Licensed firms undertook the manufacture of the Lenoir engine, which was built in sizes up to 12 horse-power. The fuel-consumption averaged slightly above 100 cubic feet of illuminating gas per brake horse-power hour under the most favorable load.

Two years previous to the appearance of the Lenoir engine, another French inventor, Hugon, had built a gas-engine almost identical with the Lenoir motor, the only difference being in the fact that the mixture entered the working-cylinder after having been compressed. Hugon considered his engine a practical failure, and it was only after Lenoir, through judicious advertising, had scored a commercial success that Hugon again turned his attention to the subject; but soon afterward he constructed a motor which, although built on a much smaller scale than Lenoir's engine, proved to be its superior in fuel-consumption.

The real basis for the gas-engine industry of the present day was formed by the experiments of a young German merchant, N. A. Otto, who in 1861 developed a small experimental engine in which admission of the mixture, compression, ignition, and exhausting the spent gases were accomplished in one cylinder. Failure to realize fully the great promises held out by this engine, due probably to inexperience and practical difficulties, caused Otto to temporarily abandon the further development of this construction. In 1863 he returned to the system indicated in the endeavors of some of his predecessors and, encouraged by the results obtained with his second experimental engine, he, in company with Eugen Langen, a practical engineer of the highest ability, constructed a «free-piston» or «atmospheric» engine, of the vertical type, in which the piston was driven upward by the combustion of the charge and transmitted power to the shaft and fly-wheel on its downward stroke only, when it was actuated by atmospheric pressure. This engine was patented in 1864, and scored its first great success at the Paris Exposition in 1867, where it was brought into competitive tests with a number of French engines built on the Lenoir and Hugon systems. Although noisy in operation, its economy was most pronounced, as it consumed less than one half the quantity of fuel used by the Lenoir, and 40 per cent less than the Hugon engines. In spite of its annoying features, more than 5,000 engines, from one half to three horse-power were placed in actual operation, and some of them can be found in use to this day.

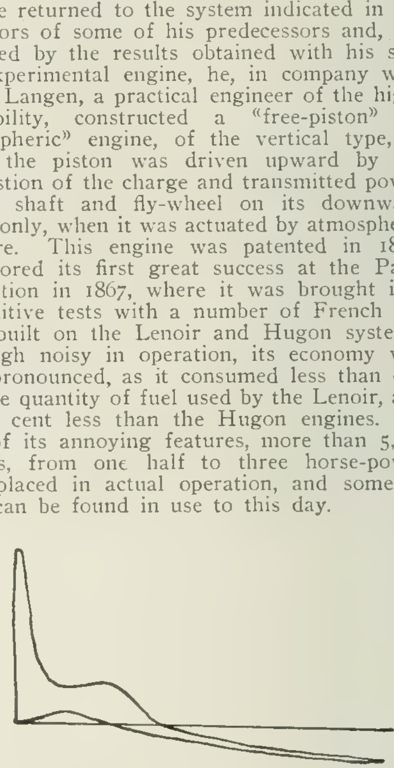

Fig. 1.— Diagram of Otto Atmospheric Engine.

In 1862, one year after Otto built his first model, a French engineer, Beau de Rochas, wrote a paper in which he set forth the advantages to be derived from the system of compressing the charge, before ignition, in the working-cylinder of the engine, and of employing four strokes of the piston (admission, compression, expansion, and exhaust) to complete one cycle of operations. This pamphlet, however, remained unknown until many years later, when it was discovered and published in the course of a patent-lawsuit directed against the claims of Otto and his associates. Beau de Rochas' idea was a brilliant theory, but he had never put it into practical use, and it was due solely to the practical success of Otto that this famous brochure was discovered. In recognition of this fact the four-stroke cycle is generally known to-day as the Otto cycle.

First American Success.— The first successful gas-engine in the United States was built

by Brayton in 1873. It was of the vertical type, with a working and a separate charging cylinder placed above the crank-shaft. A mixture of gas and air in proportion of about 1:9 was compressed to five atmospheres, or approximately 74 pounds per square inch, after which it was admitted to the working-cylinder during the early part of the downward stroke of the piston. Ignition by flame followed after one fourth of the stroke had been completed, and the expansive force thus generated gave an impulse to the piston without increase in pressure. (See Fig. 2). In order to prevent the combustion from reaching back into the chamber

Fig. 2.— Diagram of Brayton Engine.

containing the compressed mixture, several layers of wire gauze were placed into the port connecting this chamber with the working-cylinder, but with indifferent success, as the gauze was too short-lived to be reliable. Actual tests showed the thermal efficiency of the Brayton engine to be about one half that of Otto's "atmospheric" engine, although it was 33 per cent better than in the Lenoir motor. An engine of the Brayton type was built in England by Simon & Beechy, and was by them exhibited in Paris in 1878. It differed from the American model in that steam, generated by the heat of the exhaust-gases, was admitted to the cylinder together with the mixture of gas and air.

The Otto Engine.— The Paris Exposition of 1878 also introduced to the world Otto's new four-cycle engine, which at once proved a success over any other gas-engine built up to that time. Its contruction was very ingenious; it operated smoothly, was practically noiseless, and its fuel-consumption was fully as good as that of the "atmospheric" engine of the same inventor. One of its most ingenious features was the slide-valve used for the admission of air and gas and for the ignition of the compressed charge by means of a gas-flame passing from a jet in the slide-valve cover through the valve into the combustion-chamber. Many of the engines of this type built and sold at that time are in daily successful operation to this hour. It was exhibited at the grounds of the Centennial Exhibition, Philadelphia, in 1878, and became very popular in this country. As a matter of fact, most of the great number of gas-engines built in the United States are based on the Otto principle and vary only in details of construction.

Present Types.— The modern gas-engines may be divided into two classes, that of the four-cycle or Otto engine, and that of the two-cycle engine. The latter type has not been developed to nearly the same extent as the Otto cycle, and commercially has proved far less successful. It has, however, great possibilities and, with proper development, may in time supplant its rivals. To define the difference in operation of the two systems, it may be stated that in the Otto cycle, four strokes of the piston complete one cycle of operations. On the first outward stroke the mixture of fuel and air is drawn into the cylinder by the action of the piston, which in moving forward creates a partial vacuum in the space between the piston and the rear wall of the combustion-chamber. With the inlet-valves open during this stroke, the mixture will naturally flow or be inhaled into the cylinder. On the return-stroke of the piston, with all of the valves closed, the mixture is compressed to a suitable degree, the amount of compression pressure depending on the nature of the fuel used. Just previous to the beginning of the following outward movement of the piston, ignition of the compressed charge takes place. During this stroke the burning charge expands and the resulting pressure is transmitted to the engine-shaft. The last stroke of the cycle, being the second return-stroke of the piston, serves the purpose of expelling the spent gases through the exhaust-valve, which is kept open during this period. As will be seen, two revolutions of the engine-shaft are required to complete one cycle, and only during one stroke or one half of a revolution is power generated and an impulse given to the shaft.

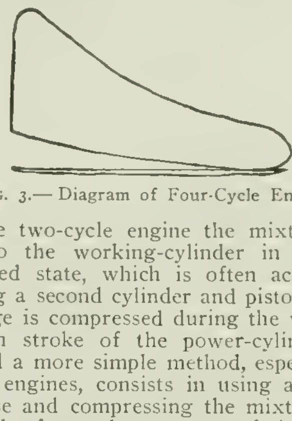

Fig. 3.— Diagram of Four-Cycle Engine.

In the two-cycle engine the mixture is admitted to the working-cylinder in a suitably compressed state, which is often accomplished by having a second cylinder and piston in which the charge is compressed during the working or expansion stroke of the power-cylinder. Another and a more simple method, especially used in small engines, consists in using an enclosed crank-case and compressing the mixture in this case by the forward movement of the working-piston. The operations take place in the following manner: While the engine is running, a charge is admitted through valves or ports opened at the proper time to the compression-cylinder or the crank-chamber, as the case may be, during the back-stroke of the power-piston. During the same time a charge previously admitted to the working-cylinder is being compressed there. On the outward stroke of the power-piston the charge in the compression-cylinder or crank-chamber is compressed and forced into the power-cylinder at the end of this period, while combustion and expansion take place in the working-cylinder. The exhaust valve is opened toward the end of this stroke, and the spent gases are expelled by the incoming new charge. A cycle of operations is therefore completed during every revolution of the crank-shaft, and an impulse given to the shaft at every forward stroke of the piston.

The Six-Cycle Engine.— During the earlier periods of the development of the gas-engine, so-called six-cycle engines were constructed. In addition to the operations taking place in the four-cycle engine, a third revolution of the shaft, or two strokes of the piston, were employed for admitting and expelling a charge of pure air, immediately after the spent gases had been exhausted. By this method of scavenging the combustion-space of the remaining products of combustion, it was expected to obtain more

economical results in fuel-consumption, but these expectations have not been realized. In recent years the construction of six-cycle engines has been practically abandoned.

The Diesel Engine.— One of the most interesting gas-engines of modern times is the Diesel, the construction of which was begun by Prof. Rudolf Diesel about 1893, and is designed to operate on gaseous, liquid, or solid fuels. The first experiments were made with an engine burning coal-dust, and at the present time it is being developed as an oil-engine, using the heavier grades of liquid fuel, such as kerosene or crude oils. Its principle, as laid down by the inventor, involves the production of the highest temperature during its cycle of operations by compression of the air before the fuel is introduced. The fuel is then gradually admitted into the heated air in a fine spray and burned instantaneously. The temperature of the gases is thus kept constant during the period of combustion, and is equal to the temperature of the compressed air before the introduction of the fuel. The early attempts to carry into practice this cycle of operations disclosed the limits to which this ideal system could be practically utilized with present materials and construction. The cycle of operations in the Diesel engine at present is as follows: During the first forward stroke of the piston, air only is admitted to the cylinder at atmospheric pressure and temperature. On the return-stroke this air is compressed to about 500 pounds' pressure per square inch, with a resulting temperature of approximately 1,000° F. Then follows the third or working stroke of the piston, during the first part of which the fuel is admitted and the combustion is maintained at constant temperature, the period of combustion depending on the amount of fuel sprayed into the heated air, which amount is controlled by the governor of the engine according to the load sustained. During the fourth stroke the spent gases are exhausted in the usual manner. In order to inject the fuel into the highly compressed air in the working-cylinder, the engine is equipped with an air-pump and reservoir, the latter being connected to the oil-spraying valve. Both the air-pump and working-cylinder are water-jacketed. The air-pump receives its air from the working-cylinder previous to the end of the compression-stroke and, after compressing it still further, transfers it to the reservoir, where a pressure of from 600 to 800 pounds per square inch is maintained, being in excess of the maximum pressure in the working-cylinder to the extent of 100 to 300 pounds per square inch.

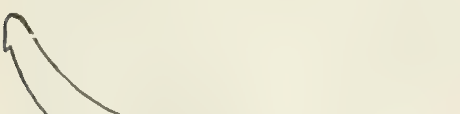

Fig. 4.—Diagram of Diesel Engine.

The accompanying diagram (Fig. 4) shows that there is no explosion, and under full load the top of the card is horizontal, resembling a card from a Corliss engine and showing a distinct cut-off. The Diesel engine is generally of the vertical type, but recently horizontal engines, both four-cycle and two-cycle, have been built in England.

Large Power-Units.— During the early periods of the introduction of the gas-engine its sizes were limited to small power-units, and it was generally considered suitable only for plants requiring not over 50 horse-power. Within the last 15 years, however, the general advance of the gas-engine industry has received a powerful impulse through the construction of large units, up to 1,000 horse-power in single cylinders, and correspondingly larger sizes in multiple-cylinder engines. Double-acting engines of the four-cycle as well as the two-cycle type, in which compression and expansion take place on both sides of the piston working in a cylinder closed at both ends, have aided materially in increasing the size of commercially successful gas-engines. The prevailing price of illuminating gas is prohibitive of its use in these large engines, but this difficulty has been overcome by the use of natural gas, of power-gas made in specially constructed generators from the cheaper grades of coal as well as from wood, and also, in recent years, by employing the waste gases of blast-furnaces and coke-ovens for the purpose of producing power in large engines operating electric generators, blowers, and other machinery. There are to-day, in Europe, a number of blast-furnaces the greater portion of the power required for the operation of which is furnished by gas-engines running on the purified and cooled gases of the high furnace. In the United States the introduction of such blast-furnace gas-engines has been somewhat retarded, but the prospect of their speedy adoption is very bright. As a matter of fact, there is now in course of construction and partial completion a modern steel-plant in the State of New York, in which practically all the power, aggregating approximately 40,000 horse-power, is furnished by gas-engines of large units.

Blast-furnace Gas.— The use of blast-furnace gas in the gas-engine forms one of the most important chapters in its history. The first trials with this fuel were made in 1894 and 1895 and, in order to make a thorough study of the difficulties that had to be overcome, small engines of 10 to 20 horse-power were first installed and operated. The presence of dust in the gas coming from the furnace proved to be the main obstacle, but through the construction of suitable scrubbers and purifiers this difficulty has been successfully remedied, and recent experiments have demonstrated beyond a doubt that the furnace-gas supplied to the gas-engine properly cleaned, contains less dust than atmospheric air under ordinary conditions.

The Modern Gas-producer.— The introduction of gas-engines of large units has led to the development of apparatus for supplying gaseous fuel for producing power at low cost, and the results achieved in this direction have been most gratifying. In the modern gas-producer, which is capable of being installed and operated as readily as a steam-boiler, a suitable gas is generated from practically all grades of fuel, from anthracite coal and coke to lignite, tan-bark, peat, and wood. While the gas-producer requires no more attendance than a steam-boiler, it is far more economical in its efficiency, and less dangerous in operation. It utilizes a greater percentage of the heat contained in the fuel than any other device. Steam-engines become

economical in very large sizes only. The average fuel-consumption in steam-plants between 100 and 500 horse-power varies from $2\frac{1}{2}$ to 4 pounds per brake horse-power hour under favorable conditions. Smaller plants show a comparatively greater fuel-consumption, 10 to 12 pounds per horse-power hour being a fair average obtained in a large number of small sizes under ordinary working conditions. Taking into consideration the degree of efficiency of the steam-boiler and engine, 12 per cent of the heat-value of the steam converted into actual work represents the best results obtained in steam-plants of large size.

The combination of the modern gas-engine and gas-producer, even in small units, shows a considerably higher efficiency. Under average working conditions, 20 to 25 per cent of the energy of the gas supplied to the engine is converted into mechanical work, and under very favorable conditions as high as 30 per cent has been obtained.

The fuel-consumption in a gas-producer and engine-plant of about 100 horse-power will not exceed $1\frac{1}{4}$ pounds of coal per brake horse-power hour, and even better results have been recorded in daily practice. It may be safely stated that the average consumption is never more than one fourth that of a steam-plant of the same size. This being an established fact, proved by years of actual practice, the increasing popularity of gas-power in all branches of industry is easily explained.

Utility of Gas-engines.— If we consider the uses to which the gas-engine is adapted, it becomes apparent that there is practically no limit to the sphere in which it is employed. At the present time it is equally suitable for any purpose for which steam and other sources of energy are applied. While it has not yet been built in units as large as steam-engines, the day is not far distant when gas-engines of 6,000 or more horse-power will be constructed and successfully operated. It is now used in places where no other source of power could be considered. Its principal advantages over steam-power are: (1) Greatly reduced floor-space; (2) complete absence of dirt, smoke, and ashes; (3) readiness for starting without tedious preparation; (4) attendance limited to cleaning and lubricating, which does not require skilled labor; (5) absolute safety from fire or explosion; (6) expense stops immediately as soon as engine is stopped by turning off the fuel.

These features, together with pronounced economy as compared with other sources of energy, have made the internal-combustion engine a favorite prime mover in all parts of the world. It has demonstrated its usefulness not only as a stationary engine, but also for the purpose of propelling vehicles of all kinds on land and water. Marine engines have been built up to 200 horse-power, and it is an interesting fact that gasoline-engines have proved to be the only suitable power for operating the submarine torpedo-boats owned by the United States government and the British admiralty. Steam-power has been tried in this class of vessels, but the heat from the boilers made it impossible for men to live in them for any length of time. Not only do the gasoline-engines now in use in these boats obviate this difficulty, but they are also of superior value on account of the limited space needed for machinery and fuel-storage.

The manufacture of horseless vehicles for pleasure and business purposes has given a powerful impulse to the development of small gasoline-engines used in propelling motor-cars. The readiness with which fuel for these engines can be obtained at almost any point, the limited weight of water and fuel required for their operation, and the extremely low cost of running them have contributed to make them the favorite motor for this class of work.

Considering the great success achieved by the gas-engine during the comparatively short time since its first introduction as a commercially successful motor, its prospects for a future bright and full of interesting developments are of the best. While the steam-engine will undoubtedly maintain its usefulness in larger sizes and in certain branches of our industries, it has found a powerful rival, capable of much greater possibilities, in the modern gas-engine.

Gas Illumination, History of. The development of gas lighting can properly be placed to the credit of the 19th century. "Spirit of Coal," produced by the distillation of coal, was known as far back as 1739, and the attention of Robert Boyle was called to this substance by Dr. Clayton, bishop of Cork. Its properties were studied and its inflammability and many of its general characteristics were known at this time, although an inflammable gas rising from the surfaces of certain stagnant pools had been noted as far back as 1659.

The first practical application of gas for illuminating purposes was made in 1792. William Murdock, an English engineer, produced gas by the destructive distillation of coal in iron retorts and conducted it for a distance of 70 feet through iron pipes and lighted and heated his house in Redruth, Cornwall. Lebon in 1801 illuminated his house and garden in Paris by gas produced from the destructive distillation of wood. This method of illumination proved a failure on account of the poor illuminating power of the gas. In 1802 Mr. Murdock installed a plant for illuminating the foundry of Watts & Bolton, near Birmingham, and a similar installation was introduced in Manchester shortly after this time.

Street lighting was introduced by F. A. Winzer (afterward changed to Winsor) in 1807 in Pall Mall. Mr. Winsor promoted a company for general gas lighting in 1809, and was granted a charter by Parliament in 1810 for the establishment of the London Gas Light and Coke Company, generally known as the Chartered Gas Company.

In America David Mellville, of Newport, R. I., was attracted by the developments made along the lines of gas lighting in England, and installed in his house, and in the streets in front of his house, the first gas lights used in the United States. This installation was made in 1806, his apparatus, with improvements, was patented in 1813; and a general installation made in several cotton mills and lighthouses.

Baltimore was the first city in the United States to install gas lighting, in the year 1817,

and since that time the growth of the gas lighting industry has proceeded uninterruptedly, for its convenience and economy have been impressed upon the public.

The original promoters of gas lighting encountered many difficulties. At the time of the installation of gas pipes in the House of Parliament, it was stipulated by this body that no pipes should be placed nearer than six inches to any wood-work. Numerous explosions and fatal asphyxiations caused by lack of experience in handling the new substance are recorded. The disagreeable and often injurious odor of the products of combustion of the gas greatly retarded its favor with the public. With the increasing experience of gas engineers, the dangers of explosions and accidental asphyxiations were eliminated. Considerable inventive genius was brought to bear to remove from the room the products of combustion, or to purify the gas for the removal of those constituents which gave the disagreeable products on burning. Several means were proposed for accomplishing these purposes. The most original improvement, and one in use at the present time, was the invention of Clegg, who introduced the use of slaked lime for removing the sulphurous constituents of the gas before it entered the holders. A later development was that of Lanning, who used ferrous oxide mixed with sawdust or wood pulp to make it porous for the absorption of the sulphur constituents. These methods are to-day in general use. Many other methods, of more or less value, have been proposed.

The illuminating power of a flame is derived from the heating of solid particles to incandescence, and the practice of gas illumination can therefore be divided into two general principles.

1. Where the solid incandescent material is supplied by the decomposition of the gas in the process of combustion.

2. Where the complete combustion of the gas is produced by the Bunsen burner, and a permanent incandescing material is supplied as a part of the apparatus.

The latter method is what is generally known as the Incandescent Gas Lighting system. The original developments in gas lighting were made on the first of these principles. The batswing or fishtail flame was produced by releasing the gas through a narrow slit, and its illumination was produced by the incandescence of the solid particles of carbon derived from the decomposing gas in the flame. The Argand gas burner is a modification of the old Argand oil burner, and consists of a ring of small openings arranged near enough together so that the gas flame is in the form of a continuous cylinder, admitting air to the inside and outside of the cylinder.

The Siemens-Lungren system, known as the Regenerative system, consisted in applying to the burner, gas and air which has been preheated.

Prof. Bunsen, professor of chemistry in Heidelberg, designed a burner to produce a non-luminous flame with complete combustion, and to give the maximum heating effect of the gas. This was accomplished by so constructing a burner that it will carry in and mix with the gas a limited amount of air before it reaches the point of combustion. The additional air necessary to produce complete combustion is drawn from the atmosphere surrounding the flame. This type is known as the Bunsen burner.

The experiments of Henry Drummond in 1826, in which he placed a solid stick of lime in the oxy-hydrogen flame, was the first systematic attempt at the development of what is now known as the Incandescent Gas Lighting system. The Drummond, or lime-light, was until recently in general use for the production of very high power lights, especially in theatres and for stereopticon practice, etc. This system, however, was not applicable to the ordinary conditions of gas lighting. A modification of the Drummond light was made by Tessie du Motay, in which he substituted coal gas for the hydrogen in the ordinary Drummond oxy-hydrogen flame. A burner exhibited at the Crystal Palace Electric and Gas Exposition in 1883, by Lewis, was constructed with a platinum mantle suspended over the flame, and designed to produce a high incandescence. This mantle, however, was unsuccesful, owing to the fact that it rapidly deteriorated by the reducing action of the gas. This burner was designed to operate with compressed air.

Clamond about the same time introduced a burner similar to the Bunsen type, in which he placed a mantle made of threads of magnesia. He also introduced an inverted pattern of burner in which a basket or mantle was made of magnesia threads held in a platinum basket. This burner, like the Lewis burner, was operated by compressed air, and was claimed to produce 4½ candles per foot of gas consumed, with a life of from 50 to 60 hours. Mantles in modification of the Clamond type were produced by C. B. Harris, in which he moulded a refractory material into sheets, pressed into the proper shape and perforated in any desired pattern. Attempts have also been made to make a mantle of asbestos or similar non-combustible material, and saturate this with a substance giving high incandescence.

The first commercially successful results accomplished in the field of Incandescent Gas Lighting were made by Dr. Carl Auer von Welsbach, of Vienna. Welsbach's work in this field began in 1880, in Bunsen's laboratory in Heidelberg, where he was studying the rare earths from a standpoint of pure chemistry. His attention was centred on the oxide of erbium. To produce a continuous light for spectroscopic study he saturated a cotton fabric with a solution of erbium, and after burning out the cotton suspended the residual ash in the flame. This produced an intense green light. The idea occurred to Welsbach to utilize this particular method for producing an ash fabric of incandescing material in the ordinary Bunsen gas flame. When this plan was communicated to Bunsen, he replied: "It appears most improbable that the oxides could be made to adhere." Welsbach, however, continued his experiments, choosing not erbium oxide, but oxides which would give a high white incandescence when heated. His researches led him through the entire field of the elements having stable oxides, and certain oxides of the so-called rare earths were found to give the most promising results.

The oxide of lanthanum made a perfect mantle in appearance and produced an intense glow in the colorless flame of a Bunsen burner, but the mantle was found to crumble to a powder within a short time.

Dr. Auer then began experiments with a view of mixing something with the lanthanum which would produce a non-slaking body. In 1887 what is known as the lanthanum-zirconium mantle was introduced. This mantle was made by saturating a closely knit cotton fabric with the proper mixture of zirconium and lanthanum nitrates, burning out the cotton and leaving a network of ash composed of the oxides of zirconium and lanthanum. These mantles gave 12 candle-power per cubic foot of gas consumed, and lasted several hundred hours. To quote Dr. Auer: "The sum of all these results appeared encouraging, and I was audacious enough to pronounce the endeavors of the gas engineers to increase the illuminating power of the open flame, as useless and vain; for it was evident that it was much more economical to renounce the lighting power of the open flame and to transform it into a Bunsen flame, and to get those substances to incandesce in the very hot part of that Bunsen flame, by which method two or three times the amount of light of an open flame could be attained."

The invention was now called to the attention of the public, and Welsbach delivered numerous lectures before the press representatives. The invention was named the Incandescent Gas Light by Mr. Sceps, editor of the *Neue Wiener Tageblätter*. The announcement of the Welsbach mantle was received with various comment, and many prominent engineers refused to take the matter seriously. Welsbach's confidence, however, was not shaken, and companies were formed for the development of the industry and the manufacture of the lighting fluid from the rare earths. The services of Dr. Ludwig Haitinger, an able chemical engineer, were added to those of Dr. Auer in the development of this work.

The increased efficiency of this method of lighting, however, was not what had been expected, and the public refused to take it up. The mantle rapidly deteriorated and required to be rejuvenated. At that time it must also be understood that these mantles were very fragile and in the early stages of the work they were delivered in the city of Vienna by a boy carrying one in each hand, as they would not bear the ordinary handling in transportation. The usual skepticism of the public in regard to new inventions prevailed, and the commercial failure of this enterprise seemed imminent. The Vienna factory was closed and the plant and laboratory sold. The American factory, under the direction of Waldron Shapleigh, was still producing with some success the lanthanum-zirconium mantle.

Welsbach, however, was not discouraged by these drawbacks, and devoted his entire attention to the development and improvement of the mantle. In the early 90's he went before the public with an entirely new mantle, which was composed of 99 per cent thorium oxide and 1 per cent cerium oxide. This mantle gave 24 candles per cubic foot of gas consumed. The present system of manufacture of mantles is entirely in accordance with this last invention of Welsbach's, which consists in saturating cotton fabric with the proper mixture of the nitrates of thorium and cerium, burning out the cotton fabric and tempering the mantle. It is then coated with collodion and packed for the market.

The development of the invention of Welsbach can be said to consist of three distinct stages:

1. The idea of saturating a cotton fabric with a lighting fluid, afterward burning out the cotton and tempering the ash.
2. The formation of the lanthanum-zirconium mantle which gave about 12 candles per cubic foot of gas consumed.
3. The thorium-cerium mantle, which gave 24 candles per cubic foot of gas consumed.

Various improvements have been made in the Bunsen burner and a large number of designs are now on the market; but the general Bunsen principle is strictly adhered to and the present Incandescent Gas Light is invariably produced by applying the incandescing material to the colorless Bunsen burner flame.

To show the wonderful development of the Incandescent Gas Lighting System attention might be called to the fact that the American Welsbach Company manufactured in 1903 20,000,000 mantles; the English Welsbach Company 10,000,000, and the combined Continental companies 60,000,000 to 70,000,000.

The wonderful ability of Welsbach as a chemist and inventor should also be noted, from the fact that the chemicals used in the production of the mantles were very rare and almost unknown, and that he was called upon to find the raw material for the production of these chemicals, and to invent processes for their extraction in a sufficiently pure state for use. All of this work was accomplished successfully after years of patient, painstaking endeavor.

Within the past decade the decorative side of gas-lighting has been all-appealing. The primary idea of gas lighting was illumination, but with a desire for greater comforts and more luxuries in the everyday life has come the desire for decorative effects. Globes, shades and domes are now made in many varieties. Color schemes of beauty are evolved, and artist and artisan combine to lend decorative worth to shape, color and treatment of the globe or shade which is destined to add to the bare illumination of the gas jet or the incandescent mantle.

Table showing efficiency of various systems of gas lighting in use at the present time:

System	Candles per Cubit Foot of Gas Consumed
Welsbach incandescent thorium-cerium mantle	22 to 24
Welsbach incandescent lanthanum-zirconium mantle	11 to 12
Siemens-Lungren burner	5 to 6
Argand flame	3 to 4
Bray burner	3 to 4
Fish-tail flame	1½ to 3

Sidney Mason,
President Welsbach Company.

Gas, Liquefied. The use of compressed ammonia gas has reached large proportions since 1890, and has proven a valuable aid in the preservation of food, the refrigeration of malt liquors, and the manufacture of ice. The introduction of the use of anhydrous ammonia has given great impetus to the manufacture of special machinery adapted to its employment in the departments named. Taken as a whole, its manufacture may be classed as a distinct industry. Although Prof. A. C. Twining, of New Haven, Conn., had in 1850 received a patent for an ice machine using ethyl ether, or other com-

pressed gas, and had in 1855 a machine of one ton capacity in operation in Cleveland, Ohio, and although in 1867, and probably earlier, the ammonia ice machines of Ferdinand Carré were in active operation, this seems to have been the first allusion in the census reports to compressed gases, and no data are there given for them. At the census of 1900 returns were made not only for compressed or liquefied ammonia (known technically as anhydrous ammonia), but also for sulphur dioxide, carbon dioxide, nitrogen monoxide (known technically as nitrous oxide), oxygen, and liquid air, the manufacture being carried on during the census year in 30 different establishments regularly devoted to this business. In addition there were six establishments reported in which liquefied gases were produced as a subordinate part of the product, the major part of the product being in some instances other than chemicals. Besides, one idle establishment was reported. Taking the returns together, it is found that there were 37 establishments devoted to this manufacture, producing $1,220,297 of products and giving employment to 251 wage-earners and $2,185,535 of capital.

Of these establishments 19, employing 181 wage-earners and $1,650,094 of capital, were engaged in producing liquefied carbon dioxide, and the output for the census year amounted to 12,196,061 pounds, of a value of $708,864. In addition, 1 establishment using carbon dioxide in manufacture reported having produced and consumed 165,000,000 pounds of this gas during the year; but, though it was compressed, it was not liquefied for use. There was employed in the manufacture of the liquefied carbon dioxide reported above, 7,027 tons of magnesite, 2,011 tons of limestone, 774 tons of coke, and 4,771 tons of sulphuric acid, and among other products there were obtained 3,095,000 pounds of Epsom salts, 3,278 tons of calcined magnesite, and 5,000 bushels of lime. About 3,500,000 pounds of the carbon dioxide reported came from fermentation or from effervescent springs.

Ten establishments employing 52 wage-earners and $453,328 in capital were engaged during the census year in producing anhydrous ammonia, and the output for the year amounted to 2,443,729 pounds, having a value of $448,157, and there were consumed in this manufacture 2,148 tons of ammonium sulphate, 4,199,708 pounds of aqua ammonia, and 83,402 bushels of lime.

Carbon Dioxide (carbonic acid gas, CO_2).—Carbon dioxide was liquefied by Faraday in glass tubes as early as 1823, through the pressure resulting from the gas being set free from combustion. In 1834 Thilorier operated this method on a much larger scale by the use of wrought-iron cylinders in place of the glass tubes. He discovered that by allowing the liquid to rapidly evaporate the reduction in temperature was so great that a portion of the CO_2 became solid. By moistening this solid CO_2 with ethyl ether he obtained a temperature of —100° C. In 1837 Dr. John Torrey, of New York, liquefied this compound in tubes and applied the liquid to guns as a propellent. In 1844 Natterer invented a pump by which very high pressures were obtained, and through which the liquefaction of carbon dioxide could be better accomplished than by the self-compression method previously used. In all these case when liquefying carbon dioxide, the gas was not only subjected to pressure, but it was also cooled. In 1869 Prof. W. N. Hill, at the United States naval torpedo station, Newport, R. I., proposed the use of liquefied CO_2 in torpedoes. In June-August, 1873, he made more than 500 pounds of the material, and the manufacture was continued at the station at intervals for some years.

In a private communication, from John B. Stobaeus, of Charles Cooper & Co., Newark, N. J., it appears that he began the liquefaction of carbon dioxide on a commercial scale in the United States in July 1884, and put the product on the market. The gas was generated from magnesite imported from Greece, by reaction with sulphuric acid, and the by-product was Epsom salts. The material was sent to the trade in steel tubes weighing about 27 pounds each, and these tubes were fitted with a valve, having a conical seat, which was invented by Mr. Stobaeus. The books of this firm show that 1,188 cylinders, containing 14,256 pounds of CO_2, were produced in 1885, and 10,704 cylinders, containing 128,448 pounds of CO_2, in 1891. The manufacture has since been taken up by others, and in addition to the method used by Mr. Stobaeus the carbon dioxide is now obtained by burning magnesite, by which magnesia is obtained as the by-product; or dolomite, by which a cement is obtained as the by-product; or marble or limestone, by which quicklime is obtained as the by-product; by treating marl with sulphuric acid; and by burning coke. The carbon dioxide issuing from effervescent mineral springs, and that produced in the fermenting tubs during the brewing of beer, is also collected and liquefied. In all of these processes the gas is washed and otherwise purified before compression.

From the data given by Mr. Stobaeus it appears that the cylinders supplied by his firm held 12 pounds of CO_2 each. The American Carbonate Company, of New York, advertise to supply cylinders in two sizes, containing 10 and 20 pounds of CO_2, respectively, representing 600 and 1,200 gallons of gas, the net weight of the cylinders being 27 and 70 pounds. Several of the companies announce that the cylinders are tested for a pressure of 3,700 pounds per square inch.

Compressed carbon dioxide is used in charging soda water, mineral water, cider, beer, and other effervescent drinks. By attaching a charged cylinder of the gas, governed by a proper regulating valve, to a barrel of beer or other beverage the liquid is not only continuously charged with the gas, but by the gas pressure the liquid is forced to the point where it is desired to serve it. By its use the old art of "krausen," which consisted in adding to stored beer, as it was being casked or bottled, some beer in the first stages of fermentation, has been displaced. Carbon dioxide is used in the manufacture of salicylic acid and of many carbonates. It is proposed for use as a medicinal agent by inhalation and in baths; for raising dough in the manufacture of aerated bread; as a refrigerating medium; as a buoyant material in raising wrecks or preventing disabled ships from sinking; and for extinguishing fires, R. Ogden Doremus having found that but 20 per cent of CO_2 in the air of the locality where fire exists is sufficient to arrest the progress of the flames. It has been used by the government as a motive power for automobile torpedoes.

Anhydrous Ammonia.— This material is the chemical substance ammonia (NH_3) in a pure and dry condition and in a compressed and liquefied state, and it is manufactured by the distillation of the ordinary 26° ammonia of commerce in a suitable apparatus. This apparatus, which should be of sufficient strength to stand a pressure of 65 pounds to the square inch, comprises a still, a condenser, three separators, and a drier or dehydrator. The still is heated by a suitable steam coil to a temperature of about 212° F., when the ammoniacal gas, together with a certain amount of water, passes off into the first separator, which latter is usually situated on the top, and forms an upward extension of, the still. In this first separator the greater portion of the watery particles carried over are eliminated by a series of perforated plates, through the perforations of which the gas had to pass, and are returned to the still through a dip pipe. From this first separator the partly dried gas passes through a water-cooled worm in the condenser, and then successively through the two other separators to the drier or dehydrator, where it is passed through a set of similarly perforated plates to those in the first separator, but having small-sized lumps of freshly burnt lime placed upon them, by which any moisture that may still remain in the gas is removed, and the completely anhydrous product can then be passed into the ammonia pump or compressor. It is found advisable to work the still at a pressure above 30 pounds to the square inch, so as to admit of the liquid being raised to a slightly higher temperature than the boiling point of water at atmospheric pressure, without causing the water to boil, the result of this being that the whole, or practically the whole, of the ammonia will be set free, while at the same time the least possible amount of the water will be vaporized and passed over with the ammonia gas.

Or it may be obtained from ammonium salts by heating them with lime and treating the gas as above described. The salt usually employed is ammonium sulphate. Aqua ammonia, or ammonia water, is of different strengths, according to the amount of NH_3 dissolved in it, but the standard strength has a specific gravity of 26° Baumé, and it contains 38.5 per cent by volume, or 26.6 per cent by weight of anhydrous ammonia. Thus 3.76 pounds of 26° ammonia will be required to make 1 pound of anhydrous ammonia. An excellent table of yields of anhydrous ammonia from 26° ammonia is given by Iltyd I. Redwood. The ammonium sulphate or sulphate of ammonia of commerce is reckoned as containing 25 per cent of anhydrous ammonia.

It is believed that some at least of the owners of ice machines produce the anhydrous ammonia that they employ, either in originally charging their machines, or in making good any loss which may take place, but there are no returns on this point. It appears also that there is some anhydrous ammonia imported, the report on "The Foreign Commerce and Navigation of the United States" from the Treasury Department placing this at 14,210 pounds, having a value of $5,870 for the year 1891, but the data for such importations as may have occurred in other years of the past decade do not appear separately.

Although Fourcroy and Vauquelin and, at about the same time, Guyton de Morveau, announced that they had accomplished the liquefaction of ammonia gas, it is believed that, as they had no suitable means for drying the gas, they failed to obtain the anhydrous ammonia. It was first certainly liquefied by Faraday in 1823, and it was not long before it was being produced in considerable quantities. Larkin and Scheffer began the commercial manufacture in St. Louis, Mo., in 1879.

Anhydrous ammonia appears, as stated above, to have first been used for refrigeration by Ferdinand Carré in his absorption machine, but it was not long before it was employed in compression machines of the type invented by Perkins and Twining, based on the refrigerating principle, which was demonstrated by Doctor Cullen in 1755; and although it has had to compete with ethyl ether, carbon dioxide, sulphur dioxide, and air, it is to-day the material which is most largely used in ice machines, and this is the principal use for this substance, though recent researches indicate that other uses will soon be found for it in chemical manufacture and in other arts.

Sulphur Dioxide (sulphurous acid gas, SO_2).— This substance is produced by burning sulphur in air or oxygen, 1 pound of sulphur giving 2 pounds of sulphur dioxide. It was liquefied by Monge and Clouet about the beginning of the 19th century. The liquefied sulphur dioxide is now a regular article of commerce, and is sent into the trade in glass "siphons" and in iron flasks, as being a convenient means of transportation and storage of the substance for use in chemical laboratories and in manufacture. The liquid has found some use in ice machines. The substance is used as a reducing agent, as a bleaching agent, and as a disinfectant. Hardin states that at present (1899) "about 4,000,000 kilogrammes of this liquid are being prepared annually."

Nitrogen Monoxide (hyponitrous oxide, nitrous oxide, laughing gas, N_2O).— This body is prepared by heating ammonium nitrate to a temperature not exceeding 258° C., when the gas is evolved. It is carefully purified, well washed, and then compressed in steel cylinders. This gas was first liquefied by Faraday in 1823. The Lennox Chemical Company began the liquefaction of the gas for the trade at Cleveland, Ohio, in 1883. The exhilarating properties of the gas were discovered by Sir Humphry Davy, who was the first to inhale it, in 1809, and it then received the name of laughing gas. It is now used as an anæsthetic agent in minor surgical operations, especially in dentistry, its use for this purpose having been suggested by Dr. Horace Wells, and it was first applied by him in the extraction of a tooth at Hartford, Conn., 11 Dec. 1844.

Oxygen.— This gas, as commercially supplied in the compressed condition, is produced by heating potassium chlorate mixed with black oxide of manganese. It is sold in the market for use in medicine by inhalation, when it is usually mixed with nitrous oxide, essential oils, and other bodies which are believed to possess therapeutic qualities. Liquid oxygen is not known to be produced commercially except as referred to under liquid air, but it was the first of the so-called permanent gases to be liquefied, this having been independently effected by Pictet and Cailletet in 1877.

Liquid Air.— Atmospheric air is a mixture of approximately 21 per cent of oxygen and 78 per cent of nitrogen by volume, with ninety-four one-hundredths of 1 per cent of argon, about four one-hundredths of 1 per cent of carbon dioxide, and variable quantities of water vapor, ammonia, and other bodies, according to locality and conditions. After 1823, when Perkins erroneously believed that he had liquefied air, numerous unsuccessful attempts were made to accomplish this result, but in 1877 Raoul Pictet and Louis Cailletet, working independently in Switzerland and in France, achieved the result on a small laboratory scale, and it was later repeated by Wroblewski, Olszewski, and Dewar, who improved the methods so as to notably increase the yields, and in 1893 Dewar froze air into a clear, transparent solid. The liquefaction of air on an industrial scale began about this time with the invention of the machines of Linde, Hampson, and Tripler, and later those of Ostergren and Burger, Dewar, Kuhn, Chase, Code, O'Doherty, Johnson, and others.

The methods may be classified as the cascade method of Pictet, Cailletet, Wroblewski, and Onnes; the self-intensive motor method of Siemens, Kuhn, and Johnson; the countercurrent free-expansion system of Linde, Hampson, Tripler, Ostergren, and Burger; and the self-intensive work method of the American Liquid Air Company, known as the Ala system. Emmens states that the principal features of the method to effect the liquefaction of air on a commercial scale were clearly described in the specifications of British patent No. 2064, granted to Charles William Siemens in 1857.

Owing to the complex composition of air, several different products are obtained by its liquefaction, notably liquid oxygen and nitrogen and solid carbon dioxide. Pictet has invented a separator by which these bodies may be rapidly separated for use, and there is thus drawn off at —70° F., solid carbon dioxide; at —290° F., commercial oxygen gas of 50 per cent purity; at —296° F., oxygen gas of 99 per cent purity; at —300° F., liquid oxygen and nitrogen gas of 95 per cent purity; at —310° F., nitrogen gas of 99 per cent purity; at —312° F., liquid air; and at —316° F., liquid nitrogen.

While many commercial uses for liquid air have been proposed, it is not known to be so used at present. It may, however, be now looked upon as a source of oxygen which promotes combustion and enables man to obtain high temperatures and high illuminating power, but it is not yet proved that this method of heating and lighting can compete economically with electricity. Liquid air does enable man to readily obtain low temperatures, which can be usefully employed in chemical operations, and a continually extending use may be looked for in this direction. Elihu Thomson has pointed out that it may find a useful application in increasing the efficiency of conductors of electricity.

Chlorine.— This gas, which may be produced by the action of muriatic acid on black oxide of manganese or by the electrolysis of common salt, is produced commercially abroad in the liquid state, but no returns are made of it in this country. It is used in chemical manufactures and for bleaching and disinfection. It is sent out to the trade in iron cylinders.

Gas, Manufactured, in America. To relate the entire history of the industry of gas-lighting it is necessary to go back no further than the beginning of the 19th century. Moreover, this statement is just as true concerning other countries as it is in relation to the United States, for while William Murdock, of England, and Philippe Lebon, of France, began to investigate the possibilities of manufacturing and distributing illuminating gas distilled from bituminous coal late in the 18th century, it was practically the dawn of the 19th century before these experiments has resulted so successfully as to establish the practicability of the project. As the question as to whether the credit for the discovery of gas properly belongs to Murdock or to Lebon is still unsettled in the minds of scientists it is useless to attempt to discuss it in such a brief review of the gas industry as this must be.

So far as we have any record the first use of illuminating gas in the United States was in 1806, when David Melville, of Newport, R. I., lighted his house and the street in front of his residence with gas made by him upon his premises. This was fully one year before the first public gas-lighting experiments were given in England, although Murdock claimed to have lighted his place in Old Cumnock with gas manufactured by himself, a little less than nine years prior to the Newport experiment. In Melville's case, however, the question of prior invention was scarcely considered. Encouraged by his success in a project that was purely original with him, he continued to improve upon his process until, in 1813, when his apparatus was so nearly perfect that he decided to patent it. A year or two later he undertook his first big contract, which was to light the cotton mill at Watertown, Mass. This being successful he applied his gas invention to the lighting of another mill at Providence, R. I., and, in 1817, he introduced his system in the illumination of lighthouses.

It was from these small beginnings that the present great industry of gas manufacture in America has grown. It was a slow growth at first, but, gradually, as the apparatus for its manufacture improved, and man's knowledge of the physical laws involved became more accurate, it began to show a more rapid increase. The first company regularly established to manufacture gas was chartered in Baltimore, Md., in 1816. In 1822, Boston adopted the gas system of lighting. In 1823, a lighting company was organized in New York, and during the next three years gas was introduced in New York city, Brooklyn, and Bristol, R.I. In 1835, the New Orleans Gas-Light Company was chartered to manufacture the new illuminant, and these were the pioneer companies in the United States. From 1835, however, the organization of such corporations continued with great rapidity, until almost every progressive city in the country was provided with a gas-lighting plant. In 1859, according to the statistical tables prepared by the "American Gas-Light Journal," there were 297 companies in the United States, working with a capital of $42,861,174, supplying a population of 4,857,000, through 227,665 private meters, while the extent of the growth of the industry from

1860 to 1900, which, while they fall below those given in the "Directory of American Gas Companies," have been pretty generally accepted by persons looking for a conservative estimate. According to the census statistics, therefore, there were in the United States, in 1900, no less than 877 gas establishments; their capital invested was in excess of $567,000,000; the value of their products aggregated $75,716,693, of which amount $69,432,582 was received directly from the sale of gas. The figures of the 12th census show an increase of nearly 84 per cent. in the amount of gas sold during the last decade of the 19th century, and while it is impossible to give anything like an authoritative statement of the number of premises at present supplied in all parts of the United States, there is little reason to believe that the estimate which places the aggregate at more than 2,000,000 is an excessive one. Several years prior to the census year it was reported that there were 134,447 premises supplied with gas in the State of Massachusetts, and more than 153,500 premises in the city of Philadelphia alone.

As the Philadelphia gas-works is operated by the city it has records which are open to the inspection of the historian. Moreover, as its history is typical of that of other early plants established to supply gas to the consumer, its story is an excellent illustration of the development of the gas corporations of that day. The first attempt to manufacture gas in Philadelphia was made in 1815. At this time it was proposed to use wood, but the experiments failed. From that day, therefore, the matter was dropped until the winter of 1826-7, when several influential citizens appeared as advocates of a project to erect gas-works and light the city with gas made from coal. Although favorably regarded in many quarters the proposition was defeated owing to the strong opposition of other Philadelphians of high standing, all of whom claimed that the introduction of gas would be dangerous to the life, limb, and health of the people. Unable to overcome such a tide of popular disapproval of the scheme, the project was dropped until 1835, when an ordinance providing for the construction and maintenance of gas-works and the distribution of gas was finally passed. According to the provisions of this ordinance, stock was issued to the amount of $100,000, and it was estimated at the time that the lighting of the entire city would require the operation of some 20,000 burners, each capable of consuming an average of four feet per hour. The plant was so fully completed as to be put into operation in 1836, and, in 1837, 17,000,000 cubic feet of gas was distributed, 6,816 private burners, and 301 public lamps being supplied. Compare this record of the first year's operations with that of the census year, when the sales in Philadelphia aggregated 7,055,559,210 cubic feet, at an average of $.0761 per 1,000.

The story of the development of the New Orleans Gas Company shows a similar growth. In 1830, the company had an output of 7,300,000 cubic feet, at $7 per 1,000; in 1840, the product had increased to 20,075,000 cubic feet, but the price was unchanged; in 1850, the output was 53,562,000 cubic feet, at $5 per 1,000; in 1860, 132,418,000, at $4.50 per 1,000; in 1870, 236,468,000, at $4. The effect of the panic of 1873 was to cause such serious depression in every line of business in New Orleans that gas sales were naturally reduced, so that, in 1880, they amounted to only 230,296,000, at $2.70 per 1,000. The period between 1880 and 1890 saw a change in the candle-power, the gas which had previously been about 16.5 being raised to 33. Thus while the record of sales for 1890 shows a consumption of only 181,497,000 cubic feet, the increase in the candle-power made the total illuminating value of the gas sold in 1890 equal to fully 363,000,000 cubic feet of the gas sold in 1880.

It was in 1837 that seven of the prominent citizens of Cincinnati procured a charter for the purpose of making and selling gas in that city. In 1843, the capital of the company was nominally $100,000, although it is scarcely probable that even so much as half that sum had been expended in building the works and the six miles of mains through which they operated. In the beginning, $3.50 per 1,000 was the price charged for gas in Cincinnati; in 1846, it was reduced to $3; in 1854, to $2.50, and since that time it has enjoyed periodical reductions until the present day, when it is sold at the price of 75 cents per 1,000 cubic feet. On 1 Jan. 1847, the company had 546 meters and 192 public lamps in use, these being supplied through 32,487 feet of main pipe, ranging from two to eight inches in diameter. In New York, the story is a similar one, for while the first company was started with small facilities, to furnish a few thousand meters and a comparatively small number of public lamps, the system had been extended to meet new requirements, until, in 1900, the annual sale of gas in New York aggregated 18,180,821,125 cubic feet, or 27.1 per cent. of the total sale of the entire country. The rate in New York during this census year was $0.905.

In the early days in the history of gas manufacture in America, soft or bituminous coal was practically the only material used. In some sections of the South gas was manufactured from rosin and pine-wood, and, during the War times, when the existence of the blockade made it almost impossible to obtain coal, nearly all the towns were glad to employ these materials in the making of gas. Compared to the old-fashioned whale-oil lamps and the tallow dips, even the wood-made gas seemed like a brilliant illuminant, whereas the best gas of that day — that which was manufactured from the soft coal — bore only a remote comparison to that which is sold at the present time, the soft coal gas having an illuminating value which was approximately not more than from 15 to 17 candle-power.

It was about this time that M. Tessie du Motay, a Frenchman, and Professor T. S. C. Lowe, the famous American æronaut, began their independent experiments in the manufacture of gas by the dissociation of steam in contact with incandescent carbon. The result of these two series of experiments, both of which were conducted in the United States, was the discovery of Du Motay's cupola-retort system, and the development of the generator-superheater system of Prof. Lowe, the latter being the most important of all inventions that had yet affected the manufacturer of gas thus, as may be seen, it was to America that the world

owes the discovery and development of the water-gas system of lighting.

The introduction of the two new systems of gas manufacture was an event of vital importance to the industry. The Municipal Company of New York was the first to construct a large plant under the Du Motay system. By this process non-luminous water-gas was generated in cupolas, carburetted with oil vapor, and passed through retorts externally heated, the gas thereafter being condensed and purified by processes very similar to those of coal-gas and other water-gas systems. Important as this improvement was, it was the Lowe process — covered by patents dated 1872 and 1875 — that was accepted as the basis of the modern water-gas system. It covers, broadly, the use, in connection with a generator in which non-luminous gas is made, of a super-heater, or fixing-chamber, fired by internal combustion, the combustible being the gases which are formed during the process of "blowing up;" that is, during and from the passage of air through the fuel in the generator. The fuel used in this generator is hard coal, or coke. The air is blown through it at a high velocity, which raises the fuel to a condition of incandescence, which fits it to dissociate the steam that has been admitted during the gas-making period. Lowe's process also covered the introduction of oil, or other enriching substances, into the non-luminous gas, and the fixing of this oil by passage through the super-heater. The first attempt to introduce the Lowe system was made at Phenixville, Pa., in 1873. A few months later, the inventor himself erected his apparatus at Conshohocken, Pa., and at Columbia, Pa.

The method which is now used in the making of water-gas is the double superheater, or improved Lowe apparatus, which was developed by the United Gas Improvement Company, the owners of the now-lapsed Lowe patents for the greater part of the country. Of course, many modifications of the two water-gas systems have been made and patented during the past quarter of a century, but none of them have been of so much importance as to deserve special attention, and while the first years of the fight for the introduction of water-gas was waged against the most bitter antagonism on the part of the coal gas interests, the product of the later inventions was so much superior in every way to the old-time coal-gas, that its growth, after it had once obtained a foothold, was very rapid. In 1880 there were less than 90 water-gas plants in the United States — about 75 of the Lowe type and 12 of the Tessie du Motay type, to be as exact as possible — but in 1890 the number had extended to such an extent that there were no less than 260 of the Lowe plants and fully 30 of the Du Motay plants in operation. By that time every city in the United States that could boast of a population of more than 400,000 had introduced water-gas, wholly or in part, while all but six of the cities with more than 50,000 inhabitants had gas made by one of these processes. Since 1890 the ratio of water-gas as compared to coal-gas has further increased until the former now represents fully 75 per cent of the total product of the country. The largest water-gas plants in the United States are the Tessie du Motay plants in New York and Baltimore, and the Lowe plants in Chicago, Boston, Providence, and the 25th Ward Works, in Philadelphia.

The victory of the water-gas interests was due to perfectly logical causes for each of the many arguments which finally obtained for the system such widespread adoption was based upon a demonstrative point of advantage. Its influence upon the mind of the consumer, however, was largely due to its advantage in the matter of candle-power. Whereas the coal-gas averaged about 15 candle-power, the water-gas that is sold is of candle-power varying from 22, which is probably the minimum, to its 35 candles in Pensacola, 33 in New Orleans, and 30 in New York, and with a probable average throughout the country of from 25 to 27 candles. Compare this, from a luminating point of view, with the conditions existing in England, where here are some companies that are chartered to furnish gas of 14 candle-power, and where not over 5 per cent of all the gas manufactured is in excess of 17 candle-power. In its ratio of purity the American water-gas is equally fortunate. The English law, for example, permits 20 grains of sulphur in forms other than sulphuretted hydrogen, and three grains of ammonia for every hundred cubic feet of gas, whereas the average of sulphur per 100 cubic feet of gas sold in the United States is seldom as great as 12 grains, while of ammonia there is only the merest trace. In one long series of analyses, which extended over a period of fully 10 years, it has been shown that the gas manufactured by this particular city contained less than 10 grains of sulphur per 100 cubic feet, and practically no ammonia.

If it had not been for the development of the water-gas process the industry of gas manufacture in American would not improbably have been doomed. The invention of this new system came at a day when the gas manufacturers were already trying to devise means of competing against cheaper oil and the improved oil lamps. A few years later the electrician appeared, and his coming had a most disastrous effect upon gas-making companies and the value of their shares. The introduction of the water-gas system, however, and the development of the improvements which followed its introduction, have been the factors which have enabled the gasman to hold his own. Although in some respects electricity furnishes a more desirable light, the high candle-power of water-gas makes it a cheaper illuminant, unit for unit, than the cheapest incandescent electric lamp. Thus, while the introduction of electric lighting systems has made some inroads into the use of gas for street lighting, and, to some extent, has reduced the sale of gas to the private consumer, practically all of the losses that may be traced to such sources have been offset by the fact that so many other uses have been found for gas besides that of illumination. The gas stove for heating and cooking purposes, the gas-engine, and the many other mechanical devices for the utilization of gaseous fuel are developments of this idea, and this branch of the business has grown so rapidly that fully 60 per cent of all the gas produced in this country is now used for fuel purposes. Then came the Welsbach lamp, the invention of Auer von Welsbach of Vienna,

which made the illuminating power of the best burners from five to seven times greater than before, and this so cheapened gas that it once more placed the gasman in a position where he could compete with the purveyor of electric illumination.

As the American gas business stands to-day it is in every sense of the word a home industry, being one of the domestic industries which is entirely independent of foreign countries for the material which it uses. When the New York Gas Company was incorporated in 1823 it made its first gas from oil; later rosin was used, and, by 1860, it was distilling English coals. During that period most of the companies imported the material from which their gas was made. Most of it came from England. Finally, however, they began to use the product of the American mines and it was soon found that none of the soft coals that could be used for gas-making purposes was superior to the bituminous coals mined in this country. The making of water-gas called for no further importations. In view of the substances from which it is made — anthracite and petroleum — there is no country in the world that can produce better materials than the United States, and while, up to a few years ago, cannel-coal was imported from Scotland and Australia for the enrichment of coal gas, beds of such coal, equal to any in the world, have since been found in the United States. So, too, as to the meters and clay retorts, which were once imported from Europe. Years ago they were supplanted by American-made goods and the gas concerns never had any that gave better satisfaction. During the early years of the gas lighting business — in fact, up to 1870 — lime was the purifying agent used by American manufacturers to the almost complete exclusion of other materials. About 1880, however, the use of oxide of iron was introduced. To-day more than three-quarters of the gas made in the United States is purified by this agent.

To tell the story of the birth and development of the gas industry in America without reference to the municipal ownership and management of gas proprieties would be impossible. Because of the dissatisfaction which was certain to exist in view of the monopolistic privileges enjoyed by some of the companies under their old charters, such things as legislative investigations and judicial injunctions were inevitable. In some places relief has been sought in the adoption of municipal ownership. Of course, it may be admitted that the charters granted during the early days were extremely favorable to the companies. It must be remembered, however, that gas-making was then an untried field and that some inducements were necessary to tempt capital to enter such an uncertain industry. As the result important concessions were offered in the form of exclusive franchises, etc., but since it has been shown that the business is a safe and profitable one legislation has been far more exacting.

Gas, Natural. *Early History.*— Natural gas is chiefly a natural combination of carbon and hydrogen, which is only about 60 per cent as heavy as air, and is highly inflammable. Its existence has been known since the earliest records of the human race as a curiosity. Perhaps the earliest historical record of the use of natural gas is that of the Apollo Oracle at Delphi in Greece, about one thousand years before the Christian Era. The Chinese are credited with the practical application of this fuel to the evaporation of salt brine for centuries.

The fire worshippers on the shores and islands of the Caspian Sea, Russia, and those of Punjab, India, have preserved a continuous flame in their temples, caused by a steady flow of natural gas for centuries. In after years it caused the deadly explosions in the deep coal mines in Europe and America, being known to the miner as fire damp. Its existence in the United States has been known since the first white men crossed the divide and explored the Ohio River watershed, as the Indians invariably conducted them to these natural vents, and, setting fire to them, viewed the effect with a semi-religious veneration. The discovery of vast reservoirs, sealed up in the porous rocks of the United States and Canada, is of recent years. The artesian driller, searching for salt brine, knew of its presence since the first wells were drilled on the western flank of the Appalachian uplift; afterward the driller in search of petroleum encountered it, but by both of these early prospectors it was considered a source of danger and annoyance. It frequently caught fire, causing loss of life and destruction of the drilling outfit by a sudden outburst.

The earliest economic use of natural gas known in the United States occurred in 1821, when it was used for the illumination of the village of Fredonia, N. Y. A well one and one half inches in diameter was drilled to a depth of 27 feet near a noted gas spring and for many years supplied the village with 30 street lights.

In 1838 a water well dug at Findlay, Ohio, encountered such quantities of a foul smelling gas that it was abandoned for the original object. It was subsequently covered up and conveyed to a house near by and utilized for domestic fuel and lights for nearly 50 years.

About the year 1841, natural gas was found in a well near Charleston, W. Va., which also supplied salt brine, from which it was separated and for many years used as a fuel for making salt.

More or less natural gas was developed in the rush to find petroleum in the valley of Oil Creek in the winter of 1859 and the year following.

One of the first attempts to employ natural gas for fuel purposes was at a well drilled at Erie, Pa., in 1868, which was soon followed by many others; these wells were only 600 feet in depth and supplied from one to three families each. Titusville, Pa., enjoys the distinction of installing the first modern equipped natural gas plant, as well as the first well drilled for petroleum. This plant was constructed during 1872, 13 years after the first oil well was drilled by Col. Drake.

During 1873 natural gas was introduced into many of the villages of Butler and Venango counties for light and fuel, being supplied from wells drilled not far distant in prospecting for petroleum. In the year 1875 the first long line (17 miles in length) was built; the pipe used was 6¼ inches in diameter, supplying the natural gas produced from the Harvey well at Larden Mills, in Butler County, Pa., to a large

manufacturing plant known as the Etna Iron Company on the Allegheny River, a few miles above Pittsburg. In the 10 years that followed slow progress was made in the actual use of the known gas wells; many were utterly ruined by pulling the casing and allowing the inflow of water, which gradually sealed up the rock and prevented the flow; this was after a struggle for years. Others were allowed to escape into the air for years. There seemed to be an uncertainty in the minds of all, as to the lasting properties of this natural product.

In the year 1876 the large Haymaker well was drilled in at Murraysville, Pa., and was not utilized until the year 1883, when its product was piped to Pittsburg. By the close of 1883 a number of pipe lines were supplying Pittsburg and the Beaver Valley with natural gas from a number of good gas wells drilled in Washington, Beaver and Butler counties. During May 1885, the first natural gas well from the deep Speechly sand was drilled, seven miles south of Oil City, Pa. During the same year the remarkable deposit of natural gas in the Grapeville pool, near Greensburg, Pa., was also found.

These numerous natural reservoirs at this period with their initial pressure seemed to convey the impression that it could be found in almost any locality and that the supply was practically inexhaustible.

In 1885 the large natural gas fields near Findlay, Ohio, became prominent and the year following large wells were also found in Indiana. These latter developments seemed to give additional assurance of its unlimited supply.

In Pennsylvania, Ohio, and Indiana immense quantities of gas were consumed in the most wasteful manner and in the extravagant display, which in numerous instances turned night into day. The effect upon witnessing mile after square mile illuminated by the burning of escaping wells and torches produced an impression long to be remembered. This extravagance and waste were not realized until many of the then known fields began to show a serious decline in the rock pressure and, knowing the original pressure, it was a simple calculation to show that a large percentage of the quantity of natural gas originally contained in the natural reservoirs had been withdrawn and that something must be done to stop the waste. Even then the reforms were slow and gradual and many companies became bankrupt. It was not until the general introduction of the gas meter in 1890 and 1891 that economy in its use by the consumer was inaugurated. Formerly the natural gas was sold by the size of the orifice through which it was delivered without regard to the manner of its combustion and use. The metre made it to the interest of the consumer to use this convenient fuel in an economical manner. It is estimated that under the metre system a saving of fully one half the gas required to accomplish the same results was made. Another economical improvement introduced consists of shutting in the wells when their flow is not required; their closing or opening being regulated by telephone from a central office. The wells are also more carefully watched and the salt water removed by pumps, instead of by blowing out as formerly. The pipe lines were thoroughly overhauled for leaks and the new pipe afterward used was heavier and of larger diameter, being supplied with heavier thimbles or improved rubber-packed joints. In the cities and towns larger distributing mains are used and a greater number of regulators secured — thereby maintaining a more even pressure — throughout all the changes in consumption, due to changes in temperature.

Production of Natural Gas in the United States.— No other country enjoys the luxury of natural gas to the extent of the people of the United States. It is used in Canada and in a very limited way in England, Germany, Rumania, Galicia, Russia, Persia, India, China, and Japan, but all these countries combined use only 2 per cent of the known world's production of this efficient and convenient fuel, leaving 98 per cent to be consumed by the people of the United States. The total value of the natural gas produced and sold since its introduction, commercially, in the United States, in 1872, up to the close of 1904, was $395,298,090. The following table is compiled from the reports of the United States Geological Survey and shows the value of the production of natural gas in the United States from 1872 to the close of 1904:

Year	Value	Year	Value
1872 to 1884.	$ 9,100,000	1895.........	$ 13,006,650
1885.........	4,857,200	1896.........	13,002,512
1886.........	10,012,000	1897.........	13,826,422
1887.........	15,817,500	1898.........	15,296,813
1888.........	22,629,875	1899.........	20,074,873

1894.........	13,954,400		
		Total......	$395,298,090

*Estimated

Assuming that 8 cents per 1,000 cubic feet was the average price for this period, this value should represent 4,941,226,100,000 cubic feet in amount. If it were possible to confine this immense quantity in a tank whose end was one square mile in area it would require to be 336 miles in length. Its heating value would equal 247,561,000 tons of coal. Large as this quantity seems, it is quite probable that it does not represent one half of the actual quantity taken from the earth's rocky reservoirs since the discovery of petroleum. The early (and in some cases the more recent practice) in developing petroleum fields, was to allow large quantities of natural gas to escape unconsumed. It is often found in the strata above that containing the petroleum and at thousands of oil wells it has been permitted to exhaust itself into the air.

Value of Natural Gas and Petroleum and Their Combined Value, by States, in 1903.— The combined value of natural gas and petroleum produced by 20 States and Territories amounted, in 1903, to $130,509,410, which is greater by $28,462,637 than $102,046,773, the combined value in 1902. Of the combined value for 1903, 27.4 per cent is the proportion furnished by sales of natural gas and 72.6 per cent is the proportion furnished by the sales of petroleum. The value of all the coal produced in the United States in 1903 was $503,724,381. In

1902 the proportion of the value of the natural gas to the petroleum produced was as 30.2 per cent to 69.8 per cent, a comparative decrease in 1903 of 2.8 per cent. These two products are so intimately connected in the strata and methods of development, that their separate and combined value by States for 1903 is appropriate and interesting.

State	Value of Natural Gas	Value of Crude Petroleum	Value of Natural Gas and Crude Petroleum
Pennsylvania	$16,182,834	$18,170,881	$34,353,715
Ohio	4,479,040	26,234,521	30,713,561
West Virginia	6,882,359	20,516,532	27,398,891
Indiana	6,098,364	10,474,127	16,572,491
Texas	21,351	7,517,479	7,538,830
California	104,521	7,399,349	7,503,870
New York	493,686	1,849,135	2,342,821
Kansas	1,123,849	988,220	2,112,069
Kentucky and Tennessee	390,601	486,083	876,684
Colorado	14,140	431,723	445,863

Indian and Oklahoma Territories	1,000	142,402	143,402
Arkansas and Wyoming	2,460	62,720	65,180
Missouri and Michigan	7,070	4,650	11,720
South Dakota	10,775	....	10,775
Illinois	3,310	....	3,310
Total	$35,815,360	$94,694,050	$130,509,410

The States that produce large quantities of natural gas, as Pennsylvania and West Virginia, distribute it to the adjoining States by a system of pipe lines, so that in some instances the natural gas consumed in a town or city is produced over 200 miles from where it is consumed. Ohio is conspicuous in the table because it consumed much more than it produced, while West Virginia produced much more than it consumed.

Natural Gas Wells and Structural Conditions of Strata.— There is a great variation in the depth of natural gas wells, owing to the diversity of the strata in which the product exists and the changing position of the underlying rocks with reference to the general surface. Some natural vents have produced natural gas in considerable quantities and have proved the incentive for drilling down to the original reservoirs, from which the gaseous fluid was escaping. Other gas wells have been discovered in drilling wells for oil or salt brine. Some of the most important gas fields have been located by expert geologists, who have traced out the summits of the anticlinals, or rock waves, for many miles from surface exposures of the strata.

The depth of wells varies from 250 to 3,000 feet, while their diameter varies from 2 inches up to 8 inches; their output, or open flow, varies from 500 cubic feet per day to 35,000,000 cubic feet per day; their shut in, or rock pressure, varies from 1 to 1,500 pounds to the square inch in extreme cases, while 300 to 400 pounds to the square inch and a volume of 1,000,000 cubic feet per day is considered a very fair well. In many of the deeper wells, two or more reservoirs of natural gas are often found. The cost varies from a few hundred dollars in the shallow shale districts to $10,000 in the deep wells in West Virginia. All large wells are usually tubed and a packer set just above the gas sand; the top of the tubing is held by clamps attached to bolts that are anchored and a heavy gate valve attached, so that the well can be shut in and the gas held in the rock when not in use.

The reservoirs in which natural gas is usually found stored when pierced by the drill, are composed of porous sandstone or limestone. In some cases a limited quantity of the gas has been found in shales, but this gas may be regarded as having gradually accumulated from the underlying rock formation. Almost invariably the large reservoirs have been developed in the strata on or near the crests of the anticlinal or rock waves, while petroleum has been generally collected on the lower horizon; and frequently salt water is found at a still lower level. Sometimes, however, the gas fields are entirely isolated from the petroleum producing areas. There are three leading requisites necessary for the accumulation of natural gas in merchantable quantity. These are as follows:

1. An open or porous strata capable of storing the gas under pressure, generally sandstone or limestone.

2. A slate or shale covering of this porous strata to seal in the upper surface and the fractures of the strata saturated with natural gas.

3. A sufficient flexure or relief of the strata to enable the separation of the salt water and the petroleum from the natural gas, which is almost invariably found in the higher portion of the strata.

These gas reservoirs have been accumulating for ages the gas they contain, gradually reaching the maximum pressure.

Original Pressure.— The original pressure of natural gas reservoirs has been found in many cases equal to the hydrostatic balance, or, in other words, to the weight of a column of water equal to the vertical distance between the reservoir and the surface of the ground. Allowing 2.3 feet for each pound, or about 43 pounds to the hundred feet, a reservoir at a depth of 1,000 feet should show 430 pounds rock pressure per square inch. This hydrostatic pressure has been equalized to a certain extent by a large number of minute vents that have permitted the escape of the lighter hydrocarbons to the surface. These vents are of common occurrence throughout the Appalachian gas field from northwestern central New York to central Tennessee and along the great Cincinnati uplift from central Kentucky to northern Ontario.

These vents have during past ages allowed

the gas to escape in immense quantities, amounting to unnumbered millions of cubic feet, so that the supplies from which we are now drawing are presumably but a small fraction of what has been produced in the earth.

Record of Natural Gas Wells.— There were 15,689 wells producing gas at the beginning of 1904. The total number of wells drilled for natural gas in 1904 was 3,095 and of this number 566 were unproductive, amounting to 18.3 per cent.

In the following table will be found the number of wells producing natural gas at the close of 1903, together with the number of unproductive or dry holes completed in the latter year, by States. The number of feet and miles of pipe lines from 2 inches up to 36 inches diameter in use at the close of 1903 is also given by States, as reported by the United States Geological Survey.

out increasing the size of the main lines, many of the large companies have erected powerful compressing plants in convenient localities. Many of these plants are models of mechanical engineering skill. The compressors are, in many cases, operated by large internal combustion engines of from 500 to 1,500 horse-power each. About 9 cubic feet only of natural gas is required to develop one horse-power and 1,000 cubic feet of natural gas at a pressure of 0 compressed to 270 pounds, by consuming 33⅓ cubic feet, or 3⅓ per cent, where very close to double this quantity is required if the natural gas be consumed under boilers and the steam used in condensing engines. There are very few known fields outside of Kansas, Indian and Oklahoma Territories, that have not been more or less depleted. The deep sand reservoirs in southwestern and central Pennsylvania and those of West Virginia should keep up a fair

State	Wells		Total Pipe Laid to Dec. 31, 1903

Exhaustion of Natural Gas Reservoirs.— Many of the original natural gas fields have been practically exhausted and a large number of the producing companies have had to seek new localities, where a fresh supply could be secured. This has been often accomplished by drilling deeper wells in more remote regions. The original gas fields adjacent to Pittsburg have been practically exhausted; most of the supply now comes from the deep natural gas sands of southwestern Pennsylvania and West Virginia, distant from 80 to 100 miles. The gas pressure in the original pool in northwestern Ohio is practically exhausted. That of central Indiana has only about 15 per cent of the original pressure and volume remaining. The newly developed field in eastern central Ohio has recently supplied a large and increasing quantity to the inhabitants of that State. West Virginia has, for the past ten and more, especially in the last four years, supplied a yearly increasing quantity of natural gas to Ohio and Pennsylvania. New York and Ohio have also been supplied by Pennsylvania. In all the natural gas fields it requires a constant drilling of new wells and connecting them to the main lines to keep up the supply, which is constantly being depleted. Owing to the decrease in pressure at the wells and the desire to deliver large quantities of natural gas to distant consumers, without increasing the size of the main lines, many

supply for many years to come. As there are no virgin fields now known to exist it will be impossible to continue the present enormous supply for a long period of years in the future. What may result from the deeper drilling of wells in localities where structural conditions are favorable, is a problem for future determination.

Occurrence, Geological Horizons, etc.— In the United States the principal sources of natural gas are located on the west slope of the great Appalachian uplift, extending from New York through Pennsylvania and West Virginia to southern central Kentucky, with a considerable portion of southeastern Ohio, also along the northern portion of the great Cincinnati uplift in northwestern Ohio and central Indiana and southeastern Kansas. There has been recently developed an important natural gas field in eastern central Ohio. These areas, briefly described, produced in 1903 99.5 per cent of the value of the entire output of the United States.

In California, Texas, Louisiana, Colorado, South Dakota, and Alaska gas is found in geologically more recent rocks, but no attempt is here made to correlate the rocks of one field with those of another. In the Mississippi valley to the eastward natural gas occurs almost universally in rocks of Palæozoic age, extending

from the highest Carboniferous down at least as far as the Trenton limestone, a distance of over 9,000 feet. The rocks vary greatly in thickness from place to place, so that no one section can be regarded as typical of all parts of the region. The 50 gas-bearing horizons known are composed of very different material, ranging from the coarser sandstones of the Upper Carboniferous and Catskill period to the finer sands of the Middle and Lower Devonian, the limy sands of the Silurian period, the crystalline limestones of the Ordovician, and the crystalline sands of the Cambrian period.

Uses.—Natural gas is used principally as a source of heat and light in the domestic service. It is employed extensively in industrial establishments for many purposes, notably in the generation of steam, in the manufacture of glass, puddling of iron, in roasting ores, in heating furnaces, in the manufacture of steel and pottery; it is also utilized as a source of power in the gas engine, used in drilling and operating oil and gas wells, and in pumping oil, and as a general source of power for all purposes. The heat value stored in natural gas is greater than that caused by any artificial combination of carbon and hydrogen, and is a perfect fuel as it issues from its original rock-sealed reservoirs. No preparation is necessary for its combustion and no residue is left. It is not affected by ordinary temperature and it is easily distributed by pipes to points of consumption. It is a most economical source of light and power, and an ideal household fuel. Lampblack is the only commercial article that is made directly from natural gas.

Illuminating Properties.—The illuminating properties of natural gas vary in different localities, because of the difference in the percentage of the heavier hydrocarbon, ethane (C_2H_6). All the natural gas found adjacent to petroleum fields has a larger proportion of ethane than the gas farther removed, and therefore the candlepower is considerably greater. Ordinary natural gas, if consumed with a common tip at the rate of 7 or 8 cubic feet per hour, will yield about 6 or 7 candlepower. In an ordinary Argand burner with chimney, it will give about 12 candlepower in consuming 5 to 6 cubic feet per hour. When natural gas is consumed in contact with a mantle of alkaline earth (thoria, etc.), the result is the cheapest and best illuminant known. When the price of natural gas is 25 cents per 1,000 cubic feet, and 50 candlepower is obtained from a consumption of 2½ cubic feet per hour, the cost per candlepower per hour is only 0.00125 of a cent.

Domestic Consumption.—There were 630,000 domestic consumers of natural gas during 1903; and it is estimated that in the western portions of New York and Pennsylvania, in central and western West Virginia, and in Ohio, Indiana, and Kansas, not less than 4,500,000 persons received the benefit of natural gas used as a fuel and an illuminant. Over 8,000 manufacturing establishments were also supplied.

The introduction of natural gas into the household, for which it is eminently fitted, has been accomplished without personal inconvenience or loss of life, except in very rare cases. The risk from fire is less than when wood and coal are used. There have been some cases of asphyxiation when a stove has been burned in a room without a flue connection, as it has been found by experiment that combustion under these conditions is imperfect, especially so as the air in the room becomes more and more saturated with carbonic acid and the vapors of water, the result being the formation of poisonous carbonic oxide.

Calorific Value.—The calorific or heat value of natural gas varies slightly in different localities, as the amounts of carbon and hydrogen vary. Those natural gases which contain the highest percentage of carbon give the best results in evaporating water. The standard used in measuring the evaporation of water is called the British thermal unit, written B. T. U., and is the amount of heat necessary to raise 1 pound of pure water 1° F. at or near 39° F., which is the temperature of the maximum density of water. The quantity of air necessary for the perfect combustion of natural gas varies from 10.4 to 10.8 parts of air to 1 part of natural gas. A number of tests have fully demonstrated that when ordinary care is taken in burning natural gas under boilers in actual service, 1 cubic foot of natural gas will do the work equivalent to the evaporation of 1 pound of water from and at 212° F. Since 20 cubic feet of ordinary natural gas weigh 1 pound, 1 pound of natural gas will evaporate 20 pounds of water, while, under similar conditions, 1 pound of petroleum will evaporate only 16 pounds of water, and 1 pound of good coal will evaporate but 10 pounds of water; therefore 10 cubic feet of natural gas or one half a pound is equal to one pound of good coal. In fact in a number of tests with a Klein or a Kirkwood burner, .87 cubic foot of natural gas has evaporated 1 pound of water from and at 212° F., which will make 17,400 cubic feet equal to one ton of good coal. The actual heating effect of natural gas as a fuel approaches much nearer the theoretical result than when coal is used. The price paid by the domestic consumer for natural gas varies in localities, ranging from 13 to 27 cents per 1,000 cubic feet. The consumers near the supply pay less than those farther off. Manufacturers pay less, ranging from 6 to 18 cents per 1,000 cubic feet. About 20,000 cubic feet of natural gas will equal one ton of good bituminous or anthracite coal. If we assume the average price to be 22 cents per 1,000, then $4.40 worth of gas will produce the same heating effect of one ton of good coal delivered in the bins — to which must be added the expense of shoveling it into the furnace and the removal of the ashes, as well as the inconvenience of the necessary dust and dirt which invariably accompanies a coal fire.

The Natural Gas Engine.—Natural gas, as applied to the internal combustion engine, has caused a complete revolution in the methods of securing power throughout the gas belt. It has in nearly all instances superseded any other source of power in pumping petroleum wells. In some instances this has been done by substituting a gas cylinder for the steam cylinder, using the same engine bed. The economy in the use of natural gas and the dispensing with the costly and troublesome boiler, with its constant attendant, has brought it into great favor for all sources of power, from a 1 horse-power up to 1,500 horse-power engine.

The following table gives the equivalents of

natural gas and coal for both the gas and steam engine per indicated horse-power per hour:

Type of Engine	Equivalent of gas and coal — Gas (*Cubic feet*)	Coal (*Pounds*)
Large natural-gas engine, highest type....	9	0.9
Ordinary natural-gas engine............	13	1.3
Triple expansion condensing steam engine.	16	1.6
Double expansion condensing steam engine.	20	2.0
Single cylinder and cut-off steam engine...	40	4.0
Ordinary high pressure, without cut-off, steam engine	80	8.0
Ordinary oil well pumping steam engine...	130	13.0

Products of Combustion.— The products of combustion are water and carbonic acid, slightly over two cubic feet of the former in the form of water vapor and about one foot of carbonic acid gas for each cubic foot of natural gas consumed; both are invisible and nearly odorless. Somewhat more than 2 cubic feet of oxygen are necessary, but, owing to the air being composed of a larger percentage of nitrogen, a little over 10 cubic feet of air is required for thorough combustion.

It has been found that in a stove without a flue connection the combustion is imperfect, especially so if the air in the room becomes more or less saturated with carbonic acid and the vapor of water from lack of fresh air. Under these conditions there is a small percentage of carbonic monoxide (CO) produced, which is a deadly and insidious poison, and if breathed by a man or an animal will soon cause death, even when a comparatively small percentage is present.

When but a small stovepipe connecting with a flue is used, recent tests have demonstrated that no carbon monoxide (CO) is formed in the room thus provided, the greater portion of the products of combustion being carried outside as the fresh air is drawn in to supply their place. On the other hand, where there is no flue or other large opening a number of fatal results and narrow escapes from asphyxiation have occurred.

Carbon monoxide (CO) does not usually exist to such an extent in the natural gas produced in West Virginia or Pennsylvania as is found elsewhere. On the other hand, analysis shows its presence in the natural gas produced in the Lima-Indiana field to the average extent of about one half of 1 per cent, and to the average extent of 1 per cent in the natural gas produced in Kansas. Formaldehyde is in some cases formed upon putting the cold surface of a teapot in contact with the gas jet of a stove, or when the gas flame impinges on the cold sheets of a steam boiler. Its presence in small quantities is made known by its pungent and irritating effect upon the nostrils and throat. The effect is dangerous, yet there are no cases known in which death has resulted from this gas thus generated.

Composition.—Analysis of natural gases and manufactured gases, their weight and heating quality per 1,000 cubic feet; also their specific gravity compared:

Constituents	Average for Penna. and W. Virginia	Average for Ohio and Indiana	Average for Kansas	Average of Coal Gas	Average of Water Gas	Average of Producer Gas from Bit. Coal
	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent

(a) 1,000 cubic feet of dry air at an atmospheric pressure of 14.7 pounds and at a temperature of 60° F. weighs 76.12 pounds and is a mechanical mixture of 23 parts of oxygen and 77 parts of nitrogen by weight.

(b) B. T. U.= British Thermal Units, which indicate the heat necessary to raise 1 pound of pure water at 39° F. one degree.

F. H. Oliphant,
Of U. S. Geological Survey, Oil City, Pa.

Gas Poisoning, poisoning by the vapor of some substance taken into the body through the air-passages. Theoretically, a large number of substances used in the arts may cause gas poisoning; practically, there are only a few that need special attention.

In general, gaseous substances reach a certain grade of concentration before they become poisonous. This varies with each gas. Forms

of gas poisoning comparatively common are numerous, particularly in Europe, where many dangerous industries are established that are here unknown. A partial list of these includes poisoning from muriatic acid gas (HCl), occurring in factories in which soda, glass, and colored wools are made or handled; from saltpetre gas (NO_3H, NO_2H), which is found in fireworks factories, and from sulphurous acid gas (SO_2), which causes trouble in wool-dyeing factories, in paper manufactories, in making sulphuric acid, in sugar-making and in disinfection. Ammonia gas (NH_3) also frequently causes poisoning; and chlorine (Cl), bromine ($Br.$), iodine (I), in gaseous form, may all cause fatal poisoning. Formaldehyde gas (CH_2O), which is being widely employed as a disinfectant, is a violent poison. Sulphuretted hydrogen (H_2S) is a severe poison, 6 per cent in the air constituting a menace to health. Practically all of these gases possess distinctive odors sufficient to give warning of their presence. Conditions in many of the industries are such, however, that they are endured at the risk of life. Even the mining of gold may be considered a hazardous trade, by reason of cyanide poisoning. It is, however, a matter of immense moment to realize that there are gaseous poisons that are destitute of any odor whatever, and hence are especially to be guarded against. The most important of these are carbon dioxide (CO_2) and carbon monoxide (CO), both of which are odorless gases in the degree of concentration sufficient to cause serious poisoning. Carbon-dioxide poisoning occurs in crowded halls, in theatres, in closed cars, in tunnels, etc., when the normal proportion of this gas is disturbed by oxygen consumption and carbon-dioxide production, the resulting poisoning being from a combination due to these two factors. Carbon-dioxide poisoning is the cause of death in drowning and hanging. (See CARBON DIOXIDE.)

Poisoning from carbon monoxide (CO) is not frequent in this country, except by the medium of illuminating gas, of which it is an important constituent, but where old-fashioned stoves without vents are used, and where there is insufficient air to convert the CO to CO_2, this form of poisoning is not uncommon. Thus the French novelist Zola is supposed to have been a victim of it.

Poisoning by illuminating gas is extremely common, occurring both by intent and accidentally. The character of the poisoning and its mode of treatment will vary with the composition of the particular variety of illuminating gas that may be inhaled. The so-called «water-gas» is particularly rich in CO. The leading symptoms of this form of poisoning are, in the beginning, headache, with sense of pressure in the temples, ringing in the ears, flashes before the eyes, beating of the temporal arteries, dizziness, and perhaps unconsciousness. At times the patient feels as though under the influence of liquor. If the breathing of the gas continues, dangerous symptoms develop. There is marked redness of the skin, with unconsciousness; the blood is bright-red — a marked contrast to the dark blood with blueness of the skin seen in carbon-dioxide poisoning. Occasionally there are cramp-like convulsions. The pulse is at first full and strong; later it is thin and small. The breathing is slowed, and becomes a kind of snoring. Vomiting is common, and occasionally the vomit is drawn into the lungs and causes the additional symptoms of suffocation. The patient may die in deep slumber. If the patient recovers, the headache and dizziness may persist for days or weeks, and changes in the pulse may be noted, with signs of sugar and albumen in the urine. From the poisoning there may occur a number of after effects. Blisters on the skin, shingles (q.v.) along the nerve-trunks, bleeding from the nose, the lungs, the liver, the kidneys, and paralysis of the extremities, may each or all develop. The diagnosis is not simple, but the chief signs are the reddish face, the snoring breathing, the absence of alcoholic breath, and perhaps the slight odor of gas in the room. The treatment should be energetic. The patient should be brought into fresh air at once, the clothing loosened, and hot bottles applied to the extremities. If the air-passages are blocked by vomited matter these should be cleared. Active rubbing of the skin with coarse towels, mustard-water applications to the extremities, and artificial respiration should be instituted. The breathing of camphor vapor, or well-diluted ammonia gas may stimulate the breathing. So long as the heart beats there are hopes of reviving the patient. The injection into the rectum of large quantities (2 quarts) of hot salt solution (110°–118° F.), a teaspoonful of salt to a pint of water, is of great service. Small quantities of whiskey (½ ounce) may be added to this. The transfusion of salt solution into the veins is sometimes necessary, but this is an operation to be performed only by the medical practitioner.

Gas Tar. See COAL TAR.

Gascoigne, găs-koin′, **William**, English astronomer: b. England about 1612; killed at Marston Moor 2 July 1644. He invented the micrometer which, as constructed by him, consisted principally of two parallel wires or metallic plates, capable of being moved, which were placed in the focus of the eye-glass of the telescope. The image was comprehended between these, and by means of a scale for the measure of angles its diameter was determined. Gascoigne used his instrument in various astronomical observations, and in determining the magnitude or distance of terrestrial objects.

Gasconade (găs-kō-nād′) **River**, southeast Missouri, an affluent of the Missouri River, fed by two head-streams rising in Webster and Wright counties. After a winding northeastward course of about 200 miles it flows into the Missouri River, 35 miles below Jefferson City. Its course is through an undulating and picturesque country, and it is navigable for nearly half its length to Arlington.

Gases, General Properties of. The word «gas» was coined by the Belgian chemist Van Helmont, in the first half of the 17th century. It was possibly suggested to him by the Dutch word «geest,» signifying a ghost or spirit, the allusion being to the apparently imponderable nature of gaseous bodies. It is known, however, that all gases possess both weight and inertia, and that they differ from other kinds of matter, in these respects, solely by reason of their lesser densities. Any object that is submersed in a gas is buoyed up by an amount equal to the weight of the gas that it displaces,

in accordance with the same principle that holds true of solids that are submersed in liquids; and in making refined determinations of the weight of an object proper allowance must be made for the difference in the buoyant effect of the air upon the object weighed, and upon the weights against which it is balanced. It will be seen that it follows, by reason of the principle of buoyancy, that no gas has any apparent weight, when it is weighed in an atmosphere identical with itself in density. If a sphere or other vessel of convenient form is weighed, both when filled with a given gas and when completely exhausted by means of an efficient air-pump, the difference in the two observations gives the weight of the gas, because the buoyant effect of the air upon the containing vessel is the same, whether it is full or empty. In this way the weights of many of the better known gases have been determined with considerable precision. Following are the densities of some of the more familiar gases, as expressed in grams per cubic centimetre at the freezing point of water, and under a barometric pressure of 76 centimetres of mercury at Paris:

Gas	Density
Dry air	0.001293
Oxygen	0.001430
Nitrogen	0.001256
Hydrogen	0.0000896
Carbon dioxid	0.001978
Carbon monoxid	0.001234
Chlorine	0.003133
Ammonia gas (NH_3)	0.000770

The fact that gases have weight and inertia, and that they are also compressible, renders the mathematical study of their internal motions especially difficult. Aerostatics and aerodynamics, which treat, respectively, of the conditions of mechanical stability of gaseous masses, and of the motions of which such masses are capable, are therefore more intricate and difficult than hydrostatics and hydrodynamics, which treat, respectively, of the equilibrium and of the motions of incompressible fluids.

A gas which is mechanically at rest exerts, against the vessel that contains it, a pressure that is everywhere perpendicular to the surface upon which it acts, and which has everywhere the same intensity, save for the slight variation due to the action of gravity,— a variation which is so slight that it can be neglected in all but the most refined physical investigations. When the gas is in motion, the case is different, and the pressure phenomena are complicated, hard to compute, and quite difficult to measure with any considerable approach to precision. In general, the internal pressure of a gas is least in those regions in which the gas is moving fastest. In a mixture of gases, each constituent contributes to the total pressure by an amount equal to the pressure that it would exert if it occupied the given space alone. Like the other gaseous laws, this one (which is known as "Dalton's law") is a close approximation to the actual fact when the density of the gas to which it is applied is not too great. At high pressures, or exceedingly low temperatures, it gives results that are measurably different from the actual facts of observation.

When a gas is subjected to a continuously increasing pressure, its behavior depends upon its temperature. If the temperature is greater than a certain critical value peculiar to each gas, it will never liquefy, no matter how great the pressure to which it is subjected; but if the temperature is lower than this critical value, the gas will ultimately condense into a liquid. (See CRITICAL POINT; GASES, LIQUEFACTION OF.) There is no essential distinction between a gas and a vapor, a "vapor" being merely a gas that is in such a condition that it may be condensed into the liquid form by a comparatively small change of temperature or pressure. The so-called "permanent gases," such as hydrogen and nitrogen, were formerly thought to be incapable of liquefaction; but it is now known that all gases can be liquefied, provided their temperatures are sufficiently reduced, and the phrase "permanent gas" is rarely used at the present day.

When the pressure of a given mass of gas is varied while the temperature remains constant, it is found that the volume is very nearly inversely proportional to the pressure. Thus if a mass of air is enclosed in a cylinder that is provided with a tightly-fitting piston, and the pressure upon it is increased so as to be five times as great as at first, the volume of the air becomes reduced to one fifth of the initial value, provided the compression is performed so slowly that the heat that is set free by it can escape by conduction and radiation. This principle, which was first discovered by the English physicist Robert Boyle, is known as "Boyle's law" in England and the United States. In continental Europe, however, it is known by the name of Mariotte, a French physicist, who discovered it independently of Boyle, but subsequently to him.

When a gas is heated under a constant pressure, its volume increases in a marked manner. All substances exhibit a change of volume under these circumstances, but in gases the change is far greater than for any other bodies, with the exception of certain liquids that are very near to their critical points. The increase in volume of a gas per degree of rise of temperature, when expressed as a fraction of the volume that the gas occupies when it is exposed (at the same constant pressure) to a temperature of 32° F., is called its "coefficient of expansion." The coefficients of expansion of the more familiar gases, such as oxygen, hydrogen, nitrogen, and carbon dioxid, are all very nearly equal; and they have, moreover, substantially the same value, whatever the constant pressure may be at which the experiment is performed. These two facts were discovered independently by Dalton, and by Gay-Lussac, and the first of the two was also discovered, previously, by the French physicist Charles, by whose name it is commonly known. Neither of these is exact, for delicate measurements have shown that the coefficient of expansion of a gas at constant pressure depends to a slight extent both upon the nature of the gas, and upon the intensity of the constant pressure at which the experiment is made. The coefficient of expansion (at constant pressure) of air, oxygen, hydrogen, nitrogen, and carbon monoxid may be taken as 0.00204 on the Fahrenheit scale, or 0.00367 on the Centigrade scale, for ordinary purposes, when the constant pressure at which the expansion takes place is not far from the ordinary atmospheric pressure. The corresponding coefficient for carbon dioxid is slightly larger than this, and may be taken as 0.00206 for the Fahrenheit scale, and 0.00371 for the Centigrade,

The increase in the pressure of a gas, when the gas is heated while its volume is kept rigorously constant, and the increase expressed as a fraction of the pressure that the same gas has when it is exposed (at the same constant volume) to a temperature of 32° F., is known as the gas's «coefficient of expansion at constant volume,» although, as a matter of fact, there is really no «expansion» at all in such a case. The coefficients of expansion of gases are very nearly identical, whether the expansion takes place at constant pressure, or at constant volume. For more precise data with respect to the expansion-coefficients of gases, see THERMOMETER; THERMOMETRY.

When a gas is allowed to expand so as to do work (by pushing a piston before it, or in any other way), the temperature of the gas falls, unless it is maintained by the addition of heat from without; the fall of temperature being due to the fact that a portion of the energy that the gas contains is used up in performing the external work. See ENERGY.

When there is absolutely no addition of energy from without, and the gas performs all the work that it is capable of performing in expanding from one of the two given pressures down to the other one, the expansion is said to be «adiabatic.» If, on the other hand, a mass of gas that is confined at a definite pressure and temperature is allowed to expand into a vacuum, it does no external work, since the vacuum opposes no resistance to it. In this case the gas is said to undergo «free expansion.» The earlier experiments of Joule upon the free expansion of air indicated that it is not attended by any change of temperature whatever. Subsequent more refined experiments executed by Joule and Kelvin, and by Natanson, upon various gases, show that in all cases free expansion is attended by a slight change of temperature. Our experimental knowledge of these slight changes is still exceedingly imperfect, which is greatly to be regretted, since a thorough understanding of the phenomena of free expansion is essential to the numerical evaluation of the absolute thermodynamical scale of temperature. See TEMPERATURE; THERMODYNAMICS.

If P_0 represents the ordinary atmospheric pressure, and V is the volume, at T° and under a pressure of P atmospheres, of a definite mass of gas whose volume is known to be V_0 at the pressure P_0 and at the freezing point of water (T being the temperature as reckoned from this freezing point), then by combining the laws of Boyle, and of Charles and Gay-Lussac, we may easily show that the pressure, temperature and volume of a gas must fulfil the simple relation $PV = P_0V_0(1 + kT)$, where k is the coefficient of expansion of the gas. Since the laws which are thus combined into one expression are only approximately true, the mathematical expression just given is also only approximate. It is very convenient for purposes of calculation, however, when it is not essential that the results which are sought should be known with the utmost accuracy. A mathematical relation of this sort, expressing the relation that must subsist between the pressure, volume and temperature of a gas, is called the «elastic equation,» or the «characteristic equation,» of the gas.

A rigorously exact equation of this sort undoubtedly exists for every gas; but its precise form is not known in any case. The equation here given is a good first approximation to it, when the gas is sufficiently removed from its critical state; but in the immediate vicinity of the critical state the foregoing equation fails utterly. A better form of characteristic equation was proposed by the Dutch physicist, Van der Waals, as follows: $P = \frac{R(1+kT)}{V-a} - \frac{b}{V^2}$ where P, V, T and k have the same significance as before, and the remaining letters represent constants peculiar to the gas considered. Van der Waals' form of the characteristic equation includes the preceding simpler one as a special case, and it represents the general nature of the phenomena in the vicinity of the critical point quite faithfully.

It has already been said that no actual gas conforms rigorously to the laws of Boyle and Charles and Gay-Lussac, and also that the change of temperature is never rigorously zero, when a gas undergoes free expansion. It is often convenient, however, especially in illustrating the principles that underlie the action of heat engines, to conceive of an ideal gas which would fulfil all these conditions absolutely. An imaginary gas of this kind is commonly called a «perfect gas.» This name is unfortunate in some respects, however. A departure from the approximate laws mentioned does not imply any actual imperfection in the gas, and it would be better to follow the lead of those writers who call the imaginary gas an «ideal gas.»

Although the coefficient of expansion of a gas is very nearly the same, whether the pressure is kept constant, or the volume, the case is very different with respect to the specific heat; for the specific heat of any gas (that is, the quantity of heat required to raise the temperature of a unit mass of the gas by one degree), is always greater when the pressure of the gas is constant, than when its volume is constant. The heat absorbed by a gas when its temperature rises is expended partly in increasing the internal energy of the gas, and partly in performing the external work that the gas does when it expands. When the volume of the gas is kept constant, no external work is done by the gas; and hence the heat absorbed is less in this case than it is when the gas is allowed to expand while being heated, so as to keep its pressure constant. The quantity of heat required to raise the temperature of a pound of water by one degree being taken as the unit, the quantity required to raise the temperature of a pound of gas by the same amount, while its pressure is kept constant, is given, for several of the more familiar gases, in the accompanying table:

GAS	Specific Heat (Constant Pressure)
Air	0.238
Oxygen	0.217
Nitrogen	0.244
Hydrogen	3.409
Chlorine	0.121
Carbon monoxid	0.244
Carbon dioxid	0.20

The specific heat of carbon dioxid has been given to only two places of decimals, because it varies considerably with the temperature.

The specific heat of a gas at constant volume is hard to measure, and hence it is usually inferred from the observed specific heat at constant pressure, together with the ratio of the two specific heats, as obtained by experiments of a different kind. In the mathematical theory of sound, for example, it is shown that the velocity with which sound will travel through a gas depends upon the ratio of the two specific heats of the gas. It is therefore possible to determine, by calculation, the ratio in question, when the actual speed of sound through a given gas has been found by experiment. The values obtained for the several gases in this way, by different observers, are not as accordant as might be desired. The ratio of the specific heat at constant pressure to that at constant volume appears to have approximately the following values: Oxygen, 1.40; hydrogen, 1.41; nitrogen, 1.41; carbon monoxid, 1.42; carbon dioxid, 1.26.

One of the best-known phenomena of gases is diffusion. Thus when two bottles containing different gases are brought together, mouth to mouth, with the lighter gas in the upper bottle, it is found that the two become perfectly mixed after a time, the lighter gas traveling downward, and the heavier one upward. This phenomenon is believed to be due to the fact that gases consist of a multitude of little particles, or molecules, which are flying about among one another with considerable speed. Many of the molecules in each bottle will in time wander into the other one, so that a sensibly homogeneous mixture eventually results.

Liquids absorb gases, or dissolve them, and sometimes in considerable amounts. Carbon dioxid, for example, is quite soluble in cold water, especially under pressure; and it is upon this fact that the possibility of preparing effervescent mineral waters and wines depends. Porous solids, like freshly prepared charcoal, will also absorb gases in considerable quantity, the gases being retained, apparently, in the form of very thin films, covering the walls of pores of the absorbent substance. (See ABSORPTION.)

When two gases combine with each other chemically, simple volumetric laws are observed, which indicate («Avogadro's law») that the number of molecules per unit of volume is the same in any two gases that have the same temperature and pressure. Two volumes of hydrogen, for example, combine with one volume of oxygen, to produce water; one volume of hydrogen combines with one volume of chlorine, to produce hydrochloric acid gas; one volume of nitrogen combines with three volumes of hydrogen, to produce ammonia gas; and so on.

(See GASES, KINETIC THEORY OF; HEAT; THERMODYNAMICS.) Consult, also: Kimball, 'Physical Properties of Gases'; 'The Laws of Gases' (miscellaneous memoirs, edited by Carl Barus); 'The Expansion of Gases by Heat' (miscellaneous memoirs, edited by W. W. Randall); Preston, 'The Theory of Heat.'

Gases, Kinetic Theory of, the theory which regards gases as aggregates of discrete particles (or «molecules») of matter that are incessantly flying about and colliding with one another, the space in which they are moving being presumably absolutely vacuous, save for the omnipresent luminiferous ether. (See ETHER.) According to this theory, the molecules which are in the outer parts of a given mass of gas must beat incessantly upon the walls of the containing vessel, flying back again from these walls in the same way that they fly away from one another after collisions among themselves. This being the case, it is plain that the walls of the containing vessel are in the same condition as a target against which a furious storm of bullets is striking perpetually. Such a storm of bullets would tend to force the target in the direction in which the bullets were moving before collision; and if the impacts were frequent enough, they would have an effect upon the target which could not be distinguished from a continuous pressure. And if we pass, in thought, from target to retaining vessel, and from bullets to molecules, we shall have a good conception of the kinetic theory of gaseous pressure. Before the behavior of molecular aggregates can be studied by mathematical methods, it is necessary to make certain assumptions with regard to the nature of the molecules. Some of the received assumptions have been made on account of their apparent necessity, and others have been made for no reason whatever, except that they simplify the mathematical treatment of the problems that arise. Thus molecules are assumed to be perfectly elastic, because it has been held to be evident that if they were not so, their incessant collisions must result in a gradual loss of velocity, which would not cease until they were all at rest. The assumption of perfect elasticity is therefore commonly regarded as a logical necessity, since we do not observe any tendency toward rest among the molecules of gases; that is, we do not perceive any tendency toward a fall of pressure, in a gas that is isolated, thermally and otherwise, from its environment. In the earlier mathematical investigations of the properties of gases, from the standpoint of the kinetic theory, the molecules were assumed, furthermore, to be exceedingly small (practically mere physical points), and they were considered to be hard, smooth, and spherical, and to exert no influence upon one another when not in actual contact; these assumptions being made, not because it was considered to be in the least degree likely that molecules have such properties, but merely in order to lessen the mathematical difficulties involved in the subsequent analysis,— difficulties that are serious enough, even when the problem is made as simple as possible. For example, they were assumed to be hard, in order that collisions might be considered as having no sensible duration. They were assumed to be exceedingly small, in proportion to the space in which they move, in order that the probability of a collision in which three or more molecules should come together at once might become vanishingly small in comparison with the probability of a collision in which the molecules come together in pairs, the discussion of the more complex collisions being thereby avoided. They were assumed to be spherical, because spheres can collide with each other in only one way; whereas other bodies (cubes, for example) can come together in the greatest variety of ways, according to their relative orientation at the moment of collision. They were assumed to be smooth, in order to avoid the necessity of taking account of the rotations that are produced when rough spheres

glance against one another obliquely. The assumptions stated above were adopted in what may be called the Maxwellian period of the development of the kinetic theory, and Maxwell and other mathematicians made elaborate investigations of the behavior of a practically infinite number of molecules having these properties, when once set in motion in a finite space.

Following are a few of the results obtained by the mathematical study of such molecules as are defined above. It is evident, in the first place, that the velocities of the various molecules are not all equal; for even if such equality existed at any given instant, it would be quickly destroyed by the inter-molecular collisions. Maxwell investigated the distribution of velocities that must subsist in a gas composed of such molecules, and gave a formula by which it is possible to calculate, at any given instant, the number of molecules that have velocities equal to, or less than, any assigned velocity. Thus if the total number of molecules present be taken as unity, the number having a velocity less than the average velocity is 0.533; the number having a velocity less than one half the average velocity is 0.112; the number having a velocity less than twice the average velocity is 0.9829; and the number having a velocity greater than four times the average velocity is 0.0000000074. It appears, therefore, that although any velocity whatever is theoretically possible (so far as Maxwell's formula is concerned), the incessant collisions bring about a sort of averaging which is effective enough to ensure that an almost vanishingly small proportion of the whole number will be actually moving with a speed as great as four times the average. The number having higher velocities falls off with still more remarkable rapidity; for example, the formula shows that less than one molecule in 10^{63} will be moving with a speed as great as 10 times the average. When two or more different kinds of molecules are simultaneously present, the molecules in each set being exactly alike and very numerous, and every molecule being hard, smooth, small, spherical, and perfectly elastic, Maxwell found that the different sets will mix with one another uniformly, and that the velocities in each set will be distributed precisely as though the other sets were not present. The average velocity in each set will be different, however, from the average velocity in every other set, the set in which the molecules are heaviest having the smallest average velocity. In fact, the velocities, in such a case, will be such that the average kinetic energy of a molecule of one set will be precisely equal to the average kinetic energy of a molecule of any other set.

Some of the mathematical difficulties that appeared almost insuperable to Maxwell have been partially overcome by other mathematicians, and, largely owing to the labors of Boltzmann, we now have a far more general form of the kinetic theory of gases. Before stating the nature of the generalizations that Boltzmann effected, it is necessary to offer a short explanation of the expression "degrees of freedom." A mathematical point is completely defined when its three co-ordinates are given; it can move by the variation of any one of these three co-ordinates, while the other two remain constant. Such a point is therefore said to possess three "degrees of freedom." A rigid body in space similarly has six degrees of freedom. Three co-ordinates must be given in order to fix the position of some one of its points,— say its centre of gravity; and it may also have three independent rotations about three independent axes passing through the point so fixed. If the rigid body is not free to rotate, or if (as in the case of the smooth spherical molecules imagined by Maxwell) there is no force acting which tends to produce rotation, the number of degrees of freedom may be considered as reduced to three, the three co-ordinates of the centre of gravity being then sufficient to define the state of the body completely. In particular, a molecule shaped like a dumb-bell may be considered to have but five degrees of freedom, if it is so smooth that collisions cannot set it in rotation about its axis of symmetry. The number of degrees of freedom of a rigid body is six, in the most general case; but if two or more rigid bodies be joined together by hinges, or any other analogous mode of connection that will allow of relative motion between the components, the number of degrees of freedom of the system so formed becomes greater than six. Thus a sytem composed of N straight rods, connected together by flexible joints at their ends, has $(2N+3)$ degrees of freedom.

Boltzmann's form of the kinetic theory may now be stated as follows: Let there be a gas composed of any number of sets of molecules, such that the molecules belonging to each set are exactly like one another, though a molecule belonging to one set may be totally unlike a molecule belonging to another set. Let these molecules have any number of degrees of freedom (which number of degrees may be different in the different sets), and let them be acted upon by parallel forces (such as gravity), or by forces tending toward fixed centres, or by internal forces (that is, forces acting within the individual molecules, between their parts). Let all the bodies be very small in comparison with the total space they occupy, so that the chance of their colliding three or more at a time is practically nothing. Moreover, let them be very numerous, and let them be perfectly elastic, and let them be smooth, so that when they collide the only force tending to make them rotate is that due to normal impact. Let them be set in motion among one another with any distribution of velocities; and let them be hard, but not infinitely so, the force called into play during collision being very great, but not necessarily infinite (as it would be if the hardness were infinite); and let the duration of a collision be exceedingly short, yet not necessarily zero. Then Boltzmann reaches the following conclusions: (1) After a short time, the law of distribution of positions and velocities in each set of the molecules will be precisely the same as it would be if all the other sets were absent; so that each set behaves as a vacuum to all the rest, so far as the distribution of velocities, and the density of aggregation of the molecules in any given region, are concerned. (2) The law of distribution of the velocities in each set is the same as that deduced by Maxwell for spherical molecules. (3) The average kinetic energy *of translation* of the molecules of any one set is equal to the average kinetic energy *of translation* of any other set. (4) The

total kinetic energy of each set of molecules (including that due to translation, rotation, etc.,) is divided up equally among the different degrees of freedom of that set. This last proposition is undoubtedly one of the most remarkable ever enunciated with regard to molecules, and it appears not to have met with unqualified acceptance among mathematicians, though there are many experimental facts which tend to show that it is at all events a good approximation to the truth.

Although Maxwell and Boltzmann agree that the percentage of molecules that have velocities much larger than the average velocity is very small, it must be remembered that according to either form of the kinetic theory there is always a certain number of molecules that have velocities of any assigned magnitude whatever; and Stoney has pointed out that if this conclusion is really sound, one consequence of it is, that the earth must be continually losing molecules of its atmosphere by their flight from the upper layers of the atmosphere, into space. A molecule of air escaping into space with a vertical velocity greater than about seven miles per second would possess sufficient momentum to carry it beyond the range of the earth's attraction forever. The loss of air that takes place in this manner is probably very gradual, but it is doubtless real, and in the course of ages it may result in the entire dissipation of the earth's atmosphere into the depths of space. It has been suggested that the absence of an atmosphere about the moon, and the apparent rarity of the atmosphere of Mars, may be due to this cause; the action having been more rapid in the cases of these two bodies, because their attractive power is smaller, and hence a larger proportion of atmospheric molecules would have the critical speed necessary to enable them to pass off into space.

It has been stated, above, that Boltzmann found that in a gaseous mixture each set of molecules would assume the same distribution that it would have if it existed in the given space alone. This corresponds to the known experimental fact that gases of different kinds will diffuse into one another, so as to eventually form a homogeneous mixture. When a bottle of some strong-smelling gas, like ammonia, is opened in a room containing still air, we cannot perceive the odor at any considerable distance until quite a time has elapsed. The molecules of the ammonia vapor are indeed moving with high velocities, but they continually strike against air molecules, rebounding from them in such a manner that in any given region there are almost as many of them returning toward the bottle as there are going away from it. They are forced to describe zigzag lines which are so very crooked that by the time an ammonia molecule has reached a point actually 10 feet distant from the bottle, it has in all probability traveled many miles. But eventually the ammonia molecules and the air molecules become thoroughly mixed, just as the kinetic theory predicts. Boltzmann's theory also teaches that in a gaseous mixture the distribution of velocities is the same in each set of molecules as it would be if that set existed in the same space alone. If the explanation of gaseous pressure suggested at the beginning of this article is correct, it follows that each constituent of the gaseous mixture will contribute to the total pressure that the gas exerts against the vessel containing it, by an amount equal to the pressure that this constituent would exert if it existed in the same space by itself. This corresponds to the known law of Dalton with regard to gaseous mixtures,— the law which states that in a gaseous mixture the total pressure is equal to the sum of the partial pressures due to the several constituents separately.

It may be shown that the average kinetic energy of translation of the molecules of a given mass of gas is sensibly proportional to the absolute temperature of the gas. This being admitted, it is easy to understand the reason for Boyle's law. (See GASES, GENERAL PROPERTIES OF.) For so long as the temperature of the gas remains constant, the average velocity of translation of the molecules also remains constant, and therefore the average effect of the blow that a molecule strikes against the walls of the containing vessel is also constant. But the pressure, in this case, will vary in direct proportion to the number of blows that the molecules strike against a unit area of the walls in a given time, and this will also vary in direct proportion to the number of molecules that a cubic inch of the gas contains. We see, therefore, that if the temperature of a gas remains constant, the pressure that the gas exerts will vary directly with the density of the gas; or, to state the same fact in another way, the pressure will be inversely proportional to the volume of the gas, which is Boyle's law.

Avogadro's law may be derived in a somewhat similar manner. Thus let P be the pressure that a gas exerts against a unit area of the containing vessel, let N be the number of molecules that it contains, per unit of volume, and let K be the average kinetic energy of translation of its molecules. Then the kinetic theory shows that the pressure of the gas can be expressed in the following manner: $P = \frac{2}{3} NK$. If two different kinds of gas are to be compared, we may conveniently distinguish the values of P, N and K that relate to the separate gases by using the subscripts 1 and 2. Then for one gas we shall have $P_1 = \frac{2}{3} N_1K_1$, and for the other $P_2 = \frac{2}{3} N_2K_2$. If the pressure is the same in both gases, we have $P_1 = P_2$, and it is easily seen that this involves the equation $N_1K_1 = N_2K_2$. Now, if the temperatures of the two gases are also equal, the average kinetic energy of translation is likewise the same in both gases; that is, $K_1 = K_2$. Taking this into account, we see that it follows that $N_1 = N_2$; or, in other words, when two gases have the same temperature and the same pressure, they also contain the same number of molecules per unit of volume; and this is Avogadro's law.

Knowing the mass of a given volume of a gas, and the pressure that the gas exerts against the boundaries that confine it, we may calculate the average speed that the constituent molecules of the gas must have, in order to produce the observed pressure. The formula by which the calculation is effected need not be given here, but some of the results are of interest. Thus it is found that at 32° F. the molecules of the more familiar gases have the following average velocities, in feet per second: Hydrogen, 5,571; oxygen, 1,394; nitrogen, 1,488; carbon dioxid,

1,491; carbon monoxid, 1,189. At higher temperatures, the velocities are greater, being proportional, for any one gas, to the square root of the absolute temperature.

A very important application of the kinetic theory of gases, which has recently been especially emphasized in connection with the determination of the atomic weight of argon (q.v.), relates to the ratio of the specific heats of a gas. Boltzmann's theory shows that if the specific heat of a gas at constant pressure be divided by its specific heat at constant volume, then the quotient can be expressed in the form $1 + \frac{2}{n}$, provided the effects of such forces as may exist between the different molecules of the gas are negligible, n being the number of degrees of freedom of the molecules of gas under consideration. This equation, it will be seen, affords a means of ascertaining the number of degrees of freedom of the molecule of a gas, by setting the foregoing expression equal to the observed value of the ratio of the specific heats, and then solving the equation for n. By this method, it has been inferred that the molecules of hydrogen, nitrogen, oxygen, and carbon monoxid have each five degree of freedom; for the ratio of the specific heats of these gases approximates closely to 1.4, which is the value of the foregoing expression for $n = 5$. If the molecules of a gas were really smooth spheres,— so smooth that they could not be set in rotation by their collisions,— then we should have $n = 3$, and hence the ratio of the specific heats would be 1.667, a value which is actually observed in the cases of argon, helium, mercury vapor, cadmium vapor, and perhaps a few other substances. Hence it is inferred that argon and helium really are elementary bodies; because it is difficult to conceive of a compound body behaving, so far as collisions are concerned, as though its molecules were smooth spheres; and if they had any other shape, it would be necessary to admit that they have at least five degrees of freedom (since it is impossible for any body in free space to have four degrees of freedom), and this would reduce the calculated value of the ratio of the specific heats to 1.400, a value which it is apparently impossible to reconcile with the results of direct observation.

Most of the results of the kinetic theory, as given above, involve the assumption that the effects of the mutual attractions that may exist between the individual molecules of a gas are small, on the whole. The forces, when they exist, may be great; but we assume that under ordinary circumstances the radius of sensible action of these forces is small in comparison with the length of the average distance that the molecules travel, between successive collisions. When, by reason of the gas being greatly compressed, this assumption becomes of doubtful validity, the foregoing conclusions become correspondingly weakened. The average distance that a molecule travels, between successive collisions, is known as its "free path"; and numerical estimates of the length of the free path have been obtained, by methods which cannot be given in the present article. Thus the free paths of some of the more familiar gases are as follows (expressed in ten millionths of an inch), the gases being supposed to be at 32° F., and under ordinary atmospheric pressure: Oxygen, 38; nitrogen, 36; hydrogen, 67; carbon monoxid, 36; carbon dioxid, 25. When the density of a gas is diminished, the average free path of the molecules increases in direct proportion to the decrease in density. Thus in the high vacua that prevail in Crooke's tubes, the mean free path may be measured in inches; the free path for hydrogen, for example, being about 6.7 inches, when the density of the gas has been reduced to the millionth of the normal density at 32° F. and atmospheric pressure.

The whole kinetic theory of gases is likely to be profoundly modified in the near future, when physicists have learned more about the "electron" (q.v.), which is now commonly regarded as the foundation unit in molecular architecture. For further details concerning the subjects touched in this article, consult Meyer, 'Kinetic Theory of Gases'; Risteen, 'Molecules and the Molecular Theory of Matter.' See also CRITICAL POINT; GASES, GENERAL PROPERTIES OF; MATTER, PROPERTIES OF; MOLECULAR THEORY; THERMODYNAMICS. A. D. RISTEEN.

Gases, Liquefaction of. It has been known for ages that matter is capable of existing in three different physical states,— the solid state, the liquid state, and the gaseous state. It has also been long known that most solids can be transformed into liquids by the application of heat, and that many liquids (water, for example,) can also be transformed into vapor by a further addition of heat. Conversely, it was known that certain aëriform substances, such as steam, can be converted into liquids by the mere abstraction of heat. It was believed, however, that an essential difference exists between gases and vapors, vapors being condensible to the liquid form, while gases were believed to be permanently aëriform, and not condensible by any experimental means at our disposal. In the early part of the 19th century the validity of this distinction came to be doubted, and Faraday, at the suggestion of Davy, undertook the systematic study of the question. He succeeded in reducing to the liquid form quite a number of gases that had previously resisted liquefaction. His general method consisted in generating the gas in large quantities in a limited space, so as to produce a very high pressure, under the influence of which (when the experiment was successful) the gas passed into the liquid state. The most convenient way of carrying out this experiment is to make use of an inverted U-shaped glass tube, one of whose legs contains a chemical preparation suitable for the generation of the gas in question, while the other end dips into a freezing mixture; the tube being hermetically sealed. If cyanide of mercury be heated in one of the legs of a tube of this kind, for example, cyanogen gas is generated in such quantities that the pressure causes a large part of it to condense in the chilled end of the tube. Chlorine was liquefied by Faraday in this manner in 1823. Shortly afterward Thilorier succeeded in solidifying carbon dioxid by the combined application of intense cold and great pressure, and Cagniard de la Tour, Regnault, Natterer, and many other experimenters, improved the methods in use with the result that many of the gases that had been previously regarded as non-condensible were reduced to

the liquid form. Oxygen, hydrogen, nitrogen, and some few other gases still resisted all attempts at liquefaction, however, and these were still called "permanent gases," although the conviction had forced itself upon physicists that all gases could be conquered, if the necessary conditions of success could be discovered. The subject was in this state when Andrews undertook his classical study of the phenomena of liquefaction of carbon dioxid. In 1863 he made the following announcement: "On partially liquefying carbonic acid by pressure alone, and gradually raising at the same time the temperature to 88° F (31° C.), the surface of demarcation between the liquid and gas became fainter, lost its curvature, and at last disappeared. The space was then occupied by a homogeneous fluid, which exhibited, when the pressure was suddenly diminished or the temperature slightly lowered, a peculiar appearance of moving or flickering striæ throughout its entire mass. At temperatures above 88° F. no apparent liquefaction of carbonic acid, or separation into two distinct forms of matter, could be effected, even when a pressure of 300 or 400 atmospheres was applied." It appeared, therefore, that a certain temperature exists, above which carbon dioxid cannot be liquefied by any pressure whatever; and this discovery was soon verified in the case of other gases. The temperature in question is known as the "critical temperature" of the gas under experiment. (For its numerical values in the cases of the more important gases, see Critical Point.) The reason that oxygen, nitrogen and hydrogen resisted previous attempts at liquefaction, even when the pressure was pushed to 3,000 atmospheres, was that the critical points of these gases are very low indeed,— far below any temperature at which the attempt at liquefaction had been made. The problem of liquefying the so-called "permanent gases" was, therefore, resolved into the production of exceedingly low temperatures. One means for the production of such temperatures was given by Thilorier, who showed that by mixing solid carbon dioxid with ordinary ether, a temperature as low as 165° F. below zero may be attained. The cold produced by the expansion of the gases themselves has also been utilized for the production of the necessary degree of cold, and in the best modern forms of apparatus the gas, after being cooled by its own expansion, is furthermore caused to circulate about the pipes that are conducting fresh supplies of gas to the point at which the expansion takes place. In all cases, every care is taken to make use of any process or device which will lower the temperature of the gas; and by the strictest attention to this general principle, it has been found possible to liquefy every known gas except helium and possibly one or two of the other rare gaseous elements recently discovered in the atmosphere. It is highly probable that these will also succumb, when they can be obtained in sufficient quantity to be treated by the same methods that have yielded success in the case of so obdurate a gas as hydrogen. Hydrogen was first liquefied, in quantity, by Dewar, in 1898. Consult: Hardin, 'Rise and Development of the Liquefaction of Gases.'

Gas'kell, Elizabeth Cleghorn Stevenson, English novelist: b. Chelsea 29 Sept. 1810; d. Alton, Hampshire, 12 Nov. 1865. She was brought up by an aunt at Knutsford in Cheshire, where she spent the greater part of her early life. This town is said to be the original of the village in her story of 'Cranford,' described as inhabited exclusively by maiden ladies and widows of limited means. She married in 1832 the Rev. William Gaskell (q.v.), a Unitarian clergyman then recently appointed minister of Cross Street Chapel, Manchester. Her first work, 'Mary Barton,' appeared in 1848. The 'Athenæum' says it raised the Lancashire dialect almost to the level of the broad Doric used by Scott in his northern novels. In this, as in most of her works, Mrs. Gaskell appears as a social reformer. Her moral and economical theories may be questioned, but as a writer of fiction she wields artistic and dramatic powers of a high order. 'Mary Barton' represents the struggles formerly so rife in Lancashire, and which have since passed in new phases and into other quarters, between workmen and employers. 'The Moorland Cottage' appeared in 1850; and in 1853, her next novel, 'Ruth,' which aims a distinct blow at the common moral judgments of society. The tale is powerfully told, but will hardly satisfy a dispassionate reader of the soundness of Mrs. Gaskell's moral theories. Her later works include: 'Cranford' (1853), an English classic, the popularity of which is constantly increasing; 'North and South' (1855); 'Sylvia's Lovers' (1860); 'Cousin Phillis' (1865); 'Wives and Daughters' (1866). In 1857 appeared a 'Life of Charlotte Bronte,' of which the 'Athenæum' observed "As a work of art we do not recollect a life of a woman by a woman so well executed."

Gaskell, William, English Unitarian clergyman: b. Latchford, near Warrington, Lancaster, 24 July 1805; d. Manchester 11 June 1884. He was graduated from the University of Glasgow in 1824; studied theology at Manchester College, York, in 1825–8; was junior minister of Cross Street Chapel, Manchester, from 1828, and senior minister from 1854. In 1840–6 he was secretary to Manchester New College, and in 1846–53 professor there of English history and literature. He also taught logic and English literature in Owens College. He was an editor of the 'Unitarian Herald' 1861–75; made a favorite rendering of Luther's 'Ein feste Burg'; wrote many original hymns, of which some appear in James Martineau's 'Hymns of Praise and Prayer' (1874); and published numerous tracts and sermons, besides 'Two Lectures on the Lancashire Dialect' (1844), appended to the 5th edition (1854) of the 'Mary Barton' of his wife, Elizabeth Cleghorn Gaskell (q.v.).

Gasoline. A colorless, inflammable fluid, the first and highest distillant of crude petroleum; an arbitrary name first given to certain gravities of naphtha used for making illuminating gas in house-plants. Specifically all gasoline is naphtha in the manufacturing laboratory. The specific gravity ranges from .58 to .90, compared with the unit 1 assumed for water, at 60° F. For every 20° F. the specific varies .01. Measured on the Baumé scale, higher specific gravities are denoted by lower numbers, and lower specific gravities by higher numbers without definite graduations. For example, a change of 6° on the Baumé scale, from 74° to 68°, means

a difference in specific gravity of .017, the increase being from .690 to .707; in the other direction a change from 74° to 80° Baumé shows a difference of .022, or a change in specific gravity from .690 to .668. Gravities from .50 to .65 are used in varnishes, paints, oilcloth manufacture, etc., as driers; gravities .65 to .68 are generally known as "stove" gasoline; .68 to .76 are used in burners for steam automobiles and in carburetters of gasoline (hydrocarbon) automobiles; higher gravities are used in cleansing establishments, and to raise the specific gravities of lower grades which contain more or less grease from lower distillation. Crude petroleum yields about 15 per cent gasoline (naphtha) for all gravities and about 4 per cent only for gravities above .76. Gasoline, like all other products of crude petroleum, was for a long time disposed of as waste in the effort to make kerosene; it was there and had to come out. In the latter sixties it was exported to Europe in small quantities. Representing the lightest portion of crude oil, gasoline is extracted by distillation, just as whiskey is produced, and in much the same sort of apparatus. The stills or retorts may be of any shape and size; both are immaterial, and practice has differed. They may be cylinders placed horizontally and in banks, or cylindrical or conical, standing perpendicular and having curved domes. Rectification is effected by a copper coil, many feet in length inside the retort and passing through the crude petroleum, carrying steam at a high pressure, assisted by a gentle direct fire varying from 122° to 257° F. Each retort has an inlet pipe for the crude petroleum and an outlet pipe for the distillant. The outlet pipe passes over the side and down to a cooling coil or worm immersed in cold running water. This worm acts as a condenser that changes back to liquid form the vapors driven off the petroleum by the heat. A smaller pipe leads from the condenser to a receiver having glass sides through which the "still-man" can watch the flow of distilled oil. From the bottom of the receiver a number of pipes lead to different storage tanks, each pipe having a cut-off valve to regulate the flow of the varying gravities to their proper tanks, each cut-off being known as a "sweeping." The first product from the retort is a gas formed by the mingling of the fumes of the petroleum with the small volume of air left in the reservoir; this is sometimes conveyed to the fire-box and used as fuel. When the first flow of the distillant reaches the receiver, the still-man tests it with a Baumé hydrometer for its specific gravity. Usually this first flow is found to be about .90 specific gravity. It is of a highly volatile nature, so nearly a gas that when exposed to air it rises in an invisible vapor and will quickly evaporate. It cannot be confined for any length of time in barrels, even if they have been successively coated inside with wax and repeatedly painted outside to make them air-tight. Even in the coldest weather it will pass through the wood. For these reasons this gravity is not put out commercially, but is used to bring up the gravity of a mass made up of lower gravities; that is to say, if .88 is being tanked the still-man lets all the .90, .89, .88 and enough of the .87 gravity oil flow into the receiver to make an average mixture of the density wanted. The oil is repeatedly tested with the hydrometer until the right gravity has been produced in the receiver, when it is let off to the proper storage tank. If .82 is the next grade wanted, all the gravities from .86 down to perhaps .78 are commingled in the receiver until a uniform fluid of the required gravity is obtained to let off into its tank. This process is called "fractioning," and is continued through gasoline into kerosene, the next distillant, down about .42 specific gravity. Gasoline is known in England as "petrol," in France as "essence." The English term is a copyrighted name first given some years ago by a refining firm called upon for high gravity naphtha by an experimenter in hydrocarbon mixtures. See PETROLEUM.

ERNEST L. FERGUSON,
Writer on Gasoline Engines and Components.

Gasom'eter, or **Gas Holder,** an inverted cylindrical vessel of sheet iron, placed in a tank of cast iron, stone, or brick containing water. A pipe ascends from the bottom of the tank through the water, to admit the gas to the space between the surface of the water and the crown of the gas holder. Sometimes a second pipe descends through the water and the bottom of the tank, for the issue of the gas to the main pipe. Frequently only one pipe is used for the inlet and outlet alternately. The water is for the purpose of retaining the gas within the vessel. The pressure of the gas raises the gas holder; and the weight of the gas holder, or such part of it as is not taken off by balance weights, impels the gas through the pipes. When balance weights are necessary, they are attached to the edge of the crown of the gas holder by long chains, which pass over pulleys on the top of columns which serve also to guide the motion of the vessel in rising and falling. Gas holders are constructed of various sizes, some exceeding 200 feet in diameter and having nearly 6,000,000 cubic feet capacity.

Gasometric Analysis. In chemistry, the art of separating, and of estimating, quantitatively, the several constituents of a gaseous mixture. The methods employed may be divided into three general classes: (1) Those based on diffusion; (2) those based upon the absorption of certain constituents by substances over or through which the mixed gases are passed; and (3) those in which the given mixture is oxidized, and its original composition inferred from an examination of the products of the oxidation. In the application of diffusion methods, the mixture is caused to pass through a porous septum of graphite, gypsum, or baked clay. The lighter constituents pass through faster than the heavier ones, so that a partial separation is effected. By causing the mixture to pass through a succession of such porous partitions, the concentration effects may be correspondingly increased. This method has been employed in many chemical researches, especially for effecting the concentration of gaseous substances that are present in a mixture in very small quantity. Its value as an experimental method was well demonstrated in connection with the study of the rare gases of the atmosphere, in effecting the separation of helium from argon. In general, the rates of diffusion of two gases are proportional to the square roots of their densities; and the density of argon being 10 times that of

helium, it follows that helium will diffuse through a porous septum about 3.2 times as fast as argon.

In the analysis of gases by the absorption of certain of their constituents by means of chemical substances, use is made of the following facts (among others): Water absorbs HCl, HBr, and HI, very readily; solid caustic potash, when moist, absorbs all acid gases, such as CO_2, SO_2, H_2S, HCl, etc.; dilute sulphuric acid absorbs all alkaline gases, such as ammonia; concentrated sulphuric acid also absorbs water, alcohol, ether, methyl oxid, and (more slowly) propylene and its homologues; alkaline solutions of pyrogallic acid absorb oxygen very readily; cuprous chlorid in solution in hydrochloric acid absorbs oxygen and carbon monoxid; and solutions of CrO_3 and of $KMnO_4$ absorb H_2S and SO_2. In the study of special problems, certain unusual absorbents also suggest themselves. Thus in the isolation of the rare gases of the atmosphere, great use was made of the fact that red-hot metallic magnesium absorbs nitrogen gas, while it is without effect upon argon, helium, and the other gases of that group.

The combustion methods are particularly applicable to those cases in which the mixture to be analyzed is capable of being burned so that the final products are water, carbon dioxid, and free nitrogen, together with excess of such gas as may have been added in order to effect the combustion. The combustion is effected in an instrument called a "eudiometer," which commonly consists of a graduated glass tube that is closed at the upper end, and which is provided with a pair of platinum electrodes fused through the glass near the closed end. A sample of the gas to be analyzed is introduced into the tube (the lower end of which dips into a mercury bath), and its volume is determined by reference to the graduation marks; readings being simultaneously taken of the thermometer and barometer, so that the observed volume of the gas can be reduced, in the subsequent calculations, to standard conditions of temperature and pressure. A known quantity of such gas as may be required to effect the combustion is next added; pure oxygen being used if the gas under examination is rich in carbon and hydrogen, and pure hydrogen being used if it is highly oxygenated or chlorinated. It is usual, also, to add a known quantity of "fulminating gas," which is prepared by the electrolysis of water, and consists of pure oxygen and hydrogen, in the proportion in which they combine to form water. The mixture is then exploded by passing an electric spark between the electrodes that are sealed into the eudiometer near its closed end, and after the heat developed by the explosive combustion has been lost by radiation, the volume of the mixture is again determined. The several constituents that remain in the eudiometer tube are then removed, one by one, by the temporary introduction, into the tube, of suitable absorbent substances. The volume of the gaseous contents of the eudiometer tube are observed after each partial absorption, and from the data so obtained the quantities of carbon, oxygen, hydrogen and nitrogen that were present in the original sample may be calculated. Consult: Hempel, 'Methods of Gas Analysis'; Sutton, 'A Systematic Handbook of Volumetric Analysis.' See also, in this encyclopedia, CHEMICAL ANALYSIS; SPECTROSCOPE.

Gasparin, Agénor Etienne, ä-zhā-nôr ā-tē-ĕn gäs-pä-răn, COMTE DE, French author: b. Orange, France, 12 July 1810; d. near Geneva, Switzerland, 4 May 1871. Elected to the Chamber in 1846, he attracted attention by his advocacy of religious liberty, prison reform, abolition of slavery, and social purity. At the outbreak of the American Civil War he published two books maintaining the justice of the Federal cause entitled, 'The Uprising of a Great People' (1861), and 'America Before Europe' (1862). Other important works were: 'Slavery' (1838); 'Christianity and Paganism' (1850); 'Liberal Christianity' (1869); 'Innocent III.,' published posthumously.

Gasparin, Valérie Boissier, vä-lā-rē bwä-sē-ā, COMTESSE DE, French author: wife of A. E. de Gasparin (q.v.): b. Geneva, Switzerland, 13 Sept. 1813; d. near Geneva 1894. Two of her works obtained the Montyon prize at the Academie Française: 'Marriage from the Christian Point of View,' and 'There are Poor in Paris and Elsewhere.' Among her other publications are: 'Journey in the South by an Ignoramus'; 'Let's Go Make a Fortune in Paris'; 'A Book for Wives'; 'Read and Judge' (strictures on the Salvation Army), and 'The Near and the Heavenly Horizons.' Several of her books were translated into English, the last named being read very widely in America in its English form.

Gaspé, gäs-pā, **Philip Aubert de,** Canadian author: b. Quebec 30 Oct. 1786; d. there 29 Jan. 1871. A lawyer, afterward sheriff, he became involved in debt for which he was imprisoned four years; and when released, secluded himself on his estate of St. Jean Port-Joli. His 'Old-Time Canadians' (1862), and his 'Memoirs' (1866), treat of Canadian traditions and folklore, and were written in French. The former was perhaps the most popular book ever published in Canada. An English translation was made by Mrs. Pennie.

Gaspé, Canada, a district in the province of Quebec, forming the northern part of the peninsula that lies between the Bay of Chaleur and the Gulf of St. Lawrence. Area, 7,500 square miles. Pop. (1901) 52,200. The name is sometimes extended to the whole peninsula. Cape Gaspé is a bold headland of the Schikshock or Notre Dame mountains, terminating the peninsula and forming the north shore of Gaspé Bay. The inhabitants are chiefly engaged in important fisheries, which with the export of lumber, form the staple industries. Gaspé, a village and port of entry in Gaspé Bay where Cartier landed in 1534, is the capital and commercial centre of the district. Pop. (1901) 454.

Gaspee, The, British revenue vessel, burned 1772. She was an armed schooner of eight guns, stationed at the entrance of Narragansett Bay to prevent that evasion of the British navigation laws which had largely built up the prosperity of the Atlantic coast and was almost the entire subsistence of Rhode Island. Its authorities connived at the traffic, and at a regular price furnished false flags, which for years passed muster, but Lieut. Dudingston of the Gaspee adopted the method of searching thoroughly every trading vessel which entered or left the bay, without regard to her flag or papers, and sending the contraband goods to

Boston for adjudication. This meant ruin to Rhode Island; the executive wrote demanding Dudingston's authority, and the chief justice sent a sheriff on board; both held that his proceedings were illegal, as he should have a commission from the governor and be sworn in. They were referred to the admiral, and then to the British secretary of state. On 9 June 1772, the regular packet left Newport for Providence without notifying Dudingston, who gave chase but ran the Gaspee aground at Namquit Point, seven miles below Providence, at low tide. That night the leading men of that city, with a company of assistants, set out in eight large boats, boarded and captured the vessel, badly wounding the commander, set the crew on shore, and burnt the schooner. The Rhode Island authorities opened an investigation with great zeal, and offered rewards for the apprehension of the guilty parties, but could discover none. The home government was greatly incensed, and appointed colonial commissioners, who sat at Newport 4–22 Jan. 1773, to make inquiry, and ordered Gov. Wanton to arrest the offenders and send them to England for trial. The governor and the chief justice applied to the assembly for instructions, which body referred it to the discretion of the chief justice, who refused to allow any arrests for transportation to be made.

Gasquet, găs'kĕt, **Francis Aidan**, English Roman Catholic ecclesiastic: b. London 5 Oct. 1846. He was educated at Downside College, Bath, and was superior of the Benedictine Monastery, and college of Saint Gregory, Downside 1878–84. He is the presiding abbot of the English Benedictines and has published: 'Henry VIII. and the English Monasteries' (1888–9); 'Edward VI. and the Book of Common Prayer' (1890); 'The Great Pestilence' (1893); 'The Last Abbot of Glastonbury' (1895); 'A Sketch of Monastic Constitutional History' (1896); 'The Old English Bible, and Other Essays' (1897); 'The Eve of the Reformation' (1900).

Gassendi (properly **Gassend**), **Pierre**, pē-ār gä-sāṅ-dē, French philosopher and mathematician: b. Champtercier, near Digne, Provence, 22 Jan. 1592; d. Paris 24 Oct. 1655. At 19 he was appointed to fill the chair of philosophy at Aix, and although the authority of Aristotle was still warmly maintained, he ventured publicly to expose the defects of his system. His lectures on this subject, 'Exercitationes Paradoxicæ adversus Aristotelem' (1624), gave great offense to the votaries of the Aristotelian philosophy, but obtained him no small reputation with others, through whose interest, after taking orders, he was made doctor of divinity. A second book of 'Exercitationes' excited so much enmity that he ceased all direct attacks on Aristotle, although he still maintained his preference for the doctrines of Epicurus, which he defended with great learning and ability. He strenuously maintained the atomic theory, in opposition to the views of the Cartesians, and, in particular, asserted the doctrine of a vacuum. On the subject of morals he explained the doctrines of Epicurus in a sense the most favorable to morality. He was appointed lecturer on mathematics in the Collége-Royal at Paris in 1645. He is ranked by Barrow among the most eminent mathematicians of the age, and mentioned with Galileo, Gilbert, and Descartes. Gassendi was the first person who observed the transit of Mercury over the sun. His chief works are: 'De Vita Moribus et Doctrina Epicuri' (1647); 'Institutio Astronomica,' 'Syntagma Philosophiæ Epicuri' (1649); 'Tychonis Brahæi Copernici, Peurbachii et Regiomontani Vitæ' (1654).

Gasterop'oda, the largest and most typical and familiar of the four classes of mollusks (phylum *Mollusca*). The name refers to the most prominent tribal characteristics, namely, that the inferior surface of the body forms a flattened sole or disk, by the contractions of which the animal advances. In all these animals the primitive symmetry of the body is obscured by the unequal development of parts, whence results the spiral disposition of the majority. The simplest gasteropods, however, such as the chiton, are symmetrical, not lop-sided like the higher forms. They have the mouth at one end of the long axis of the body, the anus at the other; the gills, kidneys, genital ducts, and circulatory organs are paired; there are two pairs (pedal and visceral) of nerve cords running parallel to one another along the body, and the ganglia are slightly developed. Of all mollusks these simplest gasteropods are probably nearest the hypothetical worm-like ancestor. When a shell is present it consists of only one piece, whence the name «univalve,» formerly applied to the class; or if of more than one piece the separate portions are placed one behind the other in the axis of the body (*Amphineura*, chitons). The gasteropods agree with the cephalopods in possessing a distinct head, containing a feeding instrument or «tongue» in the form of a lingual ribbon, but are separated from that class by the mode of formation of the shell, and by the absence of arms around the head. The lingual strap or odontophore consists of a central portion (*rachis*) and lateral pieces (*pleuræ*). On all three of these, on the central, or only on the lateral regions, are placed silicious denticles, whose number, form, and arrangement have been made the basis of classification of genera.

Mode of Life.— Though the number of terrestrial gasteropods, breathing the air directly by means of a pulmonary chamber, is very large — over 6,000 living species — those living in water are greatly in the majority, including over 10,000 forms, mostly marine. Of these, some 9,000 or so belong to the prosobranchs or *Streptoneura*, a relatively small minority being opisthobranchs and nudibranchs. The heteropods and some opisthobranchs enjoy a free-swimming pelagic life, but most marine forms frequent the coasts either on the shores or along the bottom. Deep-sea gasteropods are comparatively few. The locomotion effected by the contractions of the muscular «foot» is in almost all cases very leisurely, and the average tendency is toward sluggishness. As to diet, the greatest variety obtains; most prosobranchs with a respiratory siphon and a corresponding notch in the shell are carnivorous, and so are the active heteropods; most of the rest are vegetarian in diet. Numerous genera, both marine and terrestrial, are very indiscriminate in their feeding; others, are as markedly specialists, keeping almost exclusively to some one vegetable or animal diet. Some marine snails partial to echinoderms have got over the digestive difficulty presented by the calcareous character of the skins of their vic-

tims by a secretion of free sulphuric acid from the mouth. This acid changes the carbonate of lime into sulphate, which is brittle and readily pulverized by the rasping tongue. A few are parasitic — for example, eulima, stylifer, and the very degenerate *Entoconcha mirabilis*, all occurring in or on holothurians.

Life-history.— The eggs of gasteropods are usually small, and are surrounded with albumen, the surface of which becomes firm, while in the common snail (*Helix*) and some others there is an egg-shell of lime. The eggs not unfrequently develop into embryos within the parent, but in most cases they are laid, either singly or in masses, and often with cocoons. Few objects are more familiar on the seashore than the clustered egg-cases of the whelk, which together form a ball often about the size of an orange. Inside each of the numerous egg-cases are many embryos, but only a few reach maturity, the others serving as food material, an infantile cannibalism or struggle for existence not uncommon in the class. As to development it may be noted that the ovum divides more or less unequally, according to the amount of yolk, that a gastrula-stage occurs as usual, and that this is succeeded in typical cases, first by a «trochophore» and afterward by a «veliger» larva (see MOLLUSCA).

General Interest.— As voracious animals, furnished with powerful rasping organs, many gasteropods play an important part in the struggle for existence among marine organisms, while other terrestrial forms are most destructive devastators of vegetable and flowering plants. The manner in which numerous plants are saved from the ravages of snails, by their chemical and physical characters, is an interesting subject of investigation recently worked out by Prof. E. Stahl. From very early times, various gasteropods, such as whelks, have been utilized for human consumption and also as bait, while yet more frequently the shells, often so beautiful in form and color, have been used for the decoration of the person and the dwelling, for the basis of cameos, as domestic utensils, or even as weapons, and in many other ways. From the mucous glands of the roof of the gill-cavity in the genera *Purpura* and *Murex*, there exudes the famous secretion, at first colorless, but afterward becoming purple or violet, which furnished the ancient Tyrian dye.

Geological History.— A few gasteropods occur in strata as far back as the Cambrian, from which remote period they have continued with a steady increase. Almost all the Palæozoic genera are now extinct, and during these ages the siphon-possessing forms seem to have been almost, if not altogether, unrepresented. A host of new gasteropods appeared in the Jurassic period, and many of the modern families have their origin in Cretaceous times. Numerous as the fossil forms are, the number of types wholly extinct is comparatively small; both as regards persistence of types and increase of numbers, the gasteropods are a peculiarly successful class.

Classification.— The grouping of forms within the class is as follows, according to the latest conclusions of naturalists, as summarized by Cooke in the third volume of the Cambridge Natural History' (1894):

Class GASTEROPODA; order *Amphineura;* sub-orders, *Polyplacophora, Aplacophora;* order, *Prosobranchiata;* sub-orders, *Diotocardia, Monotocardia;* order, *Opisthobranchiata;* sub-orders, *Tectibranchiata, Ascoglossa, Nudibranchiata, Pteropoda;* order, *Pulmonata;* sub-orders, *Basommatophora, Stylommatophora.*

(For the characters of the orders see *Classification* in the article ANATOMY.) The sub-divisions are based upon different anatomical categories in each order. Thus the first sub-order of *Amphineura* embraces all the ordinary chitons having a foot and plated shell, both of which are absent in the degraded *Aplacophora*. Among the *Prosobranchiata* (which embrace the ordinary marine shells) two auricles in the heart characterize the *Diotocardia*, a single auricle the *Monotocardia*, of which the strange pelagic *Heteropoda* are now regarded as only a subordinate group. The *Opisthobranchs* are classified according to gill-features; and the *Pulmonata*, according to relative position of the eyes.

See MOLLUSCA, and consult the works cited thereunder, especially Cooke, 'Shells' (New York 1896), in which will be found many instructive references to other authorities.

Gaston, William, American jurist: b. Newbern, N. C., 19 Sept. 1778; d. Raleigh, N. C., 23 Jan. 1844. He was graduated at Princeton 1796; was admitted to the bar 1798; elected to the State Senate 1799; and congressman 1813–17, voting with the Federalists and opposing the «Loan Bill.» Returning to the practice of the law he obtained great reputation as an orator, and was frequently a member of the State legislature. He drew up the act creating the supreme court of North Carolina and served as judge of that court 1834–44. During his later years he was a Whig, opposing nullification.

Gastor'nis, a genus of fossil birds of the epyornis family, whose remains, indicating several species, have been found in the Eocene rocks of both England and France. They were birds of the size of an ostrich, with long legs, weak wings, and little if any power of flight.

Gastræa, găs-trē'a, a hypothetical primitive animal consisting simply of a sac or stomach, with an ectodermal and endodermal layer of cells. This simple organism, to which the embryonic gastrula-stage (see EMBRYOLOGY) is the nearest modern approach, and was regarded by Hæckel as recapitulative of the primitive gastræa, Hæckel assumes to have been the first animal generated on the earth, and the germ from which the whole animal kingdom with its infinite diversities was gradually evolved. His hypothesis, called the Gastræa theory, asserted that there must have been many species, families, etc., of these primitive organisms, whence all the *Metazoa* have been evolved. These generalizations were announced by Hæckel in 'Die Gastræatheorie, die Phylogenetische Classification des Thierreichs und die Homologie der Keimblätter,' published at Jena in 1874, and have since been extensively considered in all works on embryology.

Gastrec'tomy, the removal of a part or the whole of the stomach-wall. It is performed for the cure or relief of deep ulcerations, cancerous growths, or contractions of the wall that cause serious obstruction.

Gastric Juice, the secretion of the stomach, is in man a clear almost colorless fluid of acid reaction, containing one half of 1 per cent

solids. The amount secreted varies with the demand, but approximates 1,600 cubic centimetres in 24 hours. In health secretion takes place only under the stimulus of food. Hydrochloric acid, the chief constituent, is present in one or two parts per thousand. During the first stage of digestion it is all combined with the food, but later it is found free. The other important ingredients of this secretion are pepsin, a ferment that has the power of converting albuminous foods into forms that can be absorbed and assimilated; and rennin, a ferment that causes coagulation of milk by converting the casein, one of the milk proteids. Inorganic salts, the alkaline chlorides and phosphates, and phosphates of calcium, magnesium, and iron constitute most of the solids.

Gastritis, găs-trī′tĭs, a general term that includes all strictly inflammatory diseases of the stomach. Phlegmonous gastritis is a very acute, fatal, but rare disease that starts in the deeper layers of the stomach-wall and results in an abscess. Acute gastritis or acute gastric catarrh is an acute inflammation of the lining mucous membrane. The membrane becomes swollen, is covered by a coating of tenacious mucus, and tends to bleed at minute points. Errors in diet, either by over-indulgence or the ingestion of improper food, is the most frequent cause of the malady. Certain chemicals and drugs, very hot food or liquid, foreign bodies, and unripe fruits may cause the irritation. The symptoms depend on the severity of the inflammation, the milder forms being spoken of as sub-acute. Frequently premonitory symptoms, such as a feeling of fulness or tenderness, or the eructation of gases, may be noticed, and may be soon followed, in the more severe cases, by nausea, vomiting, and a rise of temperature, accompanied by painful thirst. If the retching or vomiting of mucus continues, there is apt to be great weakness and prostration. The duration of the disease under proper treatment is seldom over three or four days. The stomach should be given absolute rest for 24 hours, or even longer if nausea or retching continue. The intense thirst may be relieved by small pieces of ice, but not even the drinking of water is permitted. Rest in bed may be indicated in the more severe cases and, if so, hot poultices applied to the stomach region relieve some of the distressing symptoms. Drugs are of little value except to quiet excessive vomiting. Toxic gastritis is that form caused by the ingestion of corrosive and irritating drugs and chemicals. It is a severe form of acute catarrh, with the added effect of the particular poison taken. Strong acids and corrosives cause death of the deeper tissues, with ulceration and even perforation of the wall. The treatment depends upon the poison taken, but dilution by the imbibing of demulcent drinks is usually of value if sufficiently early. Chronic gastritis or chronic gastric catarrh is a chronic inflammatory change in the mucous membrane of the stomach. It is the most wide-spread of maladies, affecting all classes and ages. Not uncommonly successive attacks of acute gastritis, even in early life, start those progressive changes that sooner or later make themselves known as chronic catarrh. The most common cause is the repetition of insult to the stomach in food, both as to quantity and quality, and in drink irritating from high temperature or presence of alcohol. Other causes may operate, such as venous congestion from disease of the heart, liver, and spleen, changes in the blood-elements, and the constant poisoning of infectious diseases.

For an understanding of the symptoms of this affection it must be appreciated that three mechanisms make up gastric digestion — the nervous, the muscular, and the secretory. Deviation from the normal in any one of these is almost certain to act on the others, and when, in addition to these mechanisms, the close relation of the stomach and other digestive organs is considered, a marvelous complex is apparent. The symptoms of a chronic catarrh may be unnoticed, may be merely evidenced by changes due to poor gastric digestion, or interwoven with resulting derangement of all the digestive apparatus. In the early stages the mucous membrane is swelled, the gastric juice still has its normal ingredients and, in addition, the membrane secretes a mucus owing to degeneration of the cells. From this stage to a complete absence of acid, and then of ferments, the change is gradual, the final stage being known as atrophic gastritis. No symptom or group of symptoms is characteristic of the disease, the diagnosis being made with accuracy only by examination of the gastric contents. At one time or another one or more of the following symptoms are noticed. Absence of appetite, bad taste in the mouth, coated tongue, nausea and, occasionally, vomiting, eructation of gases and some liquid, heartburn, and a feeling of fulness or bloating after meals. The presence of inflammation, and the stage, are determined by chemical and microscopical analysis of the contents of the stomach after a test-meal has been eaten. In all except the atrophic stage there is always more or less mucus found mixed with the food. This is the distinguishing feature.

Of itself the disease is not fatal, but severe disorders of nutrition may result that render the sufferer more liable to other diseases.

The treatment consists in correction of the causes as much as possible, particularly in a dietetic regimen free of irritation and of ready digestibility. Lavage or washing of the stomach is of supreme importance where it can be borne. Drugs are of little use except for the relief of distressing symptoms. Where great diminution or absence of acid is found, it may be supplied, but the large amount necessary usually makes the procedure impracticable. Electricity, massage, and hydrotherapy may be beneficial.

Gastros′tomy, the operation of making a more or less permanent opening between the interior of the stomach and the overlying surface, the lining membrane of the stomach being joined to the skin entirely around the margin of the opening. This procedure is undertaken when for any reason the entrance of food into the stomach by natural passage is prevented.

Gastrot′omy, a simple incision of the wall of the stomach, usually undertaken for the exploration of the interior or for the removal of foreign bodies.

Gas′trula. See EMBRYOLOGY; GASTRÆA.

Gatacre, SIR **William Forbes,** English soldier: b. 1843; d. 6 March 1906. He joined the English army in 1862; was instructor of surveying in the Royal Military College in 1875–9;

deputy-adjutant and quartermaster-general in the Hazara Expedition in 1888, and in the Burma, Tonhon Expedition in 1889. He led the British forces in the Sudan in 1898, during the first advance against Atbara, and later commanded a British division in that region during the movement against Khartum and Omdurman. When the war in South Africa broke out he was ordered there and given an important command. He was repulsed at Stormberg with heavy loss. In April 1900 he was recalled to England.

Gatchina, gä'chē-nä. See GATSCHINA.

Gate City, The, a name given to Keokuk, Iowa (q.v.), and to Atlanta, Ga. (q.v.).

Gate of Tears, or **Gate of Mourning,** the Straits of Bab-el-Mandeb, Arabia; the term is an exact translation of the words Bab-el-Mandeb, which have reference to the many shipwrecks which anciently occurred thereabouts.

Gates, Elmer, American psychologist and inventor: b. Dayton, Ohio, 1859. He has done much original work in electric meteorology and has made several electrical mining inventions. He is the author of a system of mind-building and experimental psychology, having four laboratories for experimental research in these fields. Among his works are: 'Psychurgy or the Art of Using the Mind'; 'Art of Mind-Building.'

Gates, Horatio, American military officer: b. Maldon, Essex, England, 1728; d. New York 10 April 1806. He joined the British army early in life; in 1755 was assigned to duty at Halifax, N. S., and later served with Braddock's expedition. In July 1775 Congress appointed him adjutant-general; in 1776 he was given a command in the Northern army, and 2 Aug. 1777 assumed command of the Northern department. He defeated Burgoyne at Saratoga, 7 Oct. 1777, the British general surrounding his army on the 17th. (See SARATOGA, BATTLE OF.) In November of the same year he was appointed president of the new board of war and ordnance; and in 1778, while holding that post, sought with the aid of his friends in Congress to supersede Washington as commander-in-chief. This action soon brought him into discredit, and he resigned from active service. In June 1780 he again entered the army, becoming commander of the troops in North Carolina. On 16 August of that year, his army was defeated near Camden, S. C. He was soon afterward suspended from duty, but reinstated in his command in 1782 after the capture of Cornwallis.

Gates, Lewis Edwards, American educator and critic: b. Warsaw, N. Y., 23 March 1860. He is a brother of M. E. Gates (q.v.). He was graduated at Harvard 1884, instructor in forensics there 1884–7, instructor in English 1890–6, then becoming assistant professor of English. He is a frequent contributor of critical articles to the magazines. He has published: 'Selections from Jeffrey' (1894); 'Selections from Newman' (1895); 'Selections from Matthew Arnold' (1898); 'Three Studies in Literature' (1899); 'Studies and Appreciations' (1900).

Gates, Merrill Edward, American educator: b. Warsaw, N. Y., 6 April 1848. He was graduated at the University of Rochester 1870, was principal of the Albany Academy 1870–82, president of Rutgers College 1882–90, and president of Amherst College 1890–9. He has been very active in promoting Civil Service measures, and ballot reform. He was made chairman of the United States Board of Indian Commissioners 1884, and was president of the American Missionary Association 1893–8. He has published: 'Athens and the Greeks of To-day'; 'Sidney Lanier, Poet and Artist'; 'The Debt the School Owes the State'; 'Land and Law as Agents in Educating the Indians'; 'International Arbitration'; etc.

Gates, SIR Thomas, English colonial governor of Virginia: d. after 1621. He sailed from England in May 1609, in charge of a colony of 500 emigrants to the New World, but his vessel, the Sea Venture, was stranded on the rocks of Bermuda. Here the passengers built two new ships and finally reached Virginia in May 1610. Gates went to England in the meantime and returned in 1611 with 300 more emigrants. He was made governor the same year and held that office till 1614, when he returned to England.

Gatesville, Texas, city and county-seat of Coryell County, on the St. Louis S. R.R., 80 miles north of Austin. It is situated in the fertile valley of the Leon River, and has considerable agricultural, stock-raising, and produce-shipping interests. Pop. (1900) 1,865.

Gath. See TOWNSEND, GEORGE ALFRED.

Gath (Heb. «wine-press»), one of the five cities of the Philistines which were presided over by so many princes or lords from the time of Joshua to a comparatively late period. It was situated on the borders of Judah, and was in consequence a place of much importance in the wars of the Jews and the Philistines. It is stated in Joshua that Gath was one of the cities in which, at the time of the conquest, there still remained some of the ancient Anakims or giants, and they appear to have perpetuated the race here till much later times, for it was from Gath that the renowned Goliath issued. The exact site of the ancient city cannot be determined with any degree of certainty, but some identify it with the eminence Tell-es-Sâfieh, about midway between Ekron and Ashdod.

Gath'mann Gun. See ORDNANCE.

Gatineau, gä-tē-nō, a river of Canada, in the province of Quebec, rising in a large lake of the same name, from which it flows south, and falls into the Ottawa opposite the town of Ottawa. Its total length is 450 miles.

Gatling, Richard Jordan, American inventor: b. Hertford County, N. C., 12 Sept. 1818; d. New York 1903. While a boy he assisted his father in perfecting a machine for sowing cotton seed, and another for thinning out cotton plants. Subsequently he invented a machine for sowing rice. Removing to St. Louis in 1844, he adapted this invention to sowing wheat in drills. For several winters he attended medical lectures in Cincinnati, and in 1849 removed to Indianapolis, where he engaged in railroad enterprises and real estate speculations. In 1850 he invented a double-acting hemp brake, and in 1857 a steam plow, which, however, he did not bring to any practical result. In 1861 he conceived the idea of the revolving battery gun which bears his name. Of these he constructed six at Cincinnati, which were destroyed by the burning of his factory. Afterward he had 12 manufactured elsewhere, which were

used by Gen. Butler on the James River. In 1865 he improved his invention, and in the year following, after satisfactory trial, it was adopted into the United States service. It has also been adopted by several European governments. At the time of his death he was perfecting a few business formalities prior to placing his new motor plow on the market. Although best known as the inventor of a terrible death-dealing weapon, he was the gentlest and kindliest of men. The sight of returning wounded soldiers early in the Civil War led him to consider how war's horrors might be alleviated. By making war more terrible, it seemed to him nations would be less willing to resort to arms, and he accordingly devoted himself to the study of ordnance and ballistics, with this end in view.

Gatling Gun. See ORDNANCE.

Gatschet, Albert Samuel, American linguist: b. Berne, Switzerland, 3 Oct. 1832. He was educated at the universities of Berne and Berlin, and removing to New York in 1868 made a special study of the languages of the American Indians. In 1879 he became connected with the Bureau of American Ethnology. He is the author of: 'The Klamath Indians of Southwestern Oregon'; 'A Greek Migration Legend'; etc.

Gatty, Margaret Scott, English writer for young people: b. Burnham, Essex, England, 3 June 1809; d. Ecclesfield, Yorkshire, 3 Oct. 1873. She was married to Rev. Alfred Gatty in 1839. Her career in letters was begun with 'The Fairy Godmother and Other Tales' (1851); but 'Parables from Nature' (1855–71) was the most popular and still holds its place in public favor. She edited 'Aunt Judy's Magazine' (1866–73).

Gauchos, gow'chōz, hybrid inhabitants of South America, mostly cattle-raisers of nomadic habits. They are natives of the pampas, and descendants of Spaniards and Indians. The white strain has largely faded out from them, and a modified Indian type has been developed which has an ethnological interest. As a distinct people, however, they may be said to be disappearing. They are now mainly confined to the Chaco region. Many of them possess figures and bearing which show a proud descent. They wear a costume picturesque in fashion and color, and their skill as horsemen and in using the lasso and bolas is remarkable. They subsist almost wholly on meat, and are noted for their hardiness, bravery, and free mode of existence.

Gauden, gâ'dĕn, **John,** English bishop: b. Mayland, Essex, 1605; d. 20 Sept. 1664. In the early part of his life he belonged to the popular party. After the outbreak of the civil war, he hesitatingly submitted to the Presbyterian discipline, omitted the liturgy from the Church service, and even subscribed to the covenant, although he secretly wrote a treatise against it. After the Restoration he was appointed chaplain to Charles II., and successively created bishop of Exeter and of Worcester. He claimed the authorship of the 'Eikon Basilike,' or the 'Portraiture of his Sacred Majesty in his Solitudes and Sufferings,' a work which was once almost universally attributed to Charles himself, and which in one year went through 50 editions. Hallam and Sir James Mackintosh pronounce his claim valid. Other works of his are: 'Cromwell's Bloody Slaughter House' (1660); 'Tears of the Church' (1659). See EIKON BASILIKE.

Gauge, gāj, the name of many different instruments and appliances used for measuring various dimensions, forces, etc. The various kinds of gauge are distinguished by means of special names indicating the use to which they are applied. Among the most important contrivances of this nature are the instruments fixed to engine boilers for registering the force of the steam and the level of the water. In one of its simplest forms the pressure or steam gauge consists of a bent siphon-tube, with two unequal legs, partly filled with mercury. The top of the shorter limb is connected to a short pipe, which enters that part of the boiler which contains the steam; the other end is open to the atmosphere. A stop-cock is generally placed between the gauge and the boiler, so that it may be put in communication with the boiler at pleasure. When the stop-cock is open, the steam, acting on the mercury in one leg of the gauge, presses it down, and the mercury in the other leg rises. The difference between the two columns is the height of mercury which corresponds to the excess of the pressure of the steam in the boiler above the pressure of the atmosphere. For high-pressure engines, however, the steam-gauge usually works in the manner of an aneroid barometer, a pointer moving on a circular scale under the influence of the motion of a corrugated diaphragm; or, as in the Bourdon gauge, the tendency of a bent tube to straighten itself under the influence of the steam pressure communicates movement in a similar manner to a pointer or index hand. The water-gauge is a vertical glass tube called a gauge-glass, communicating above and below with the boiler. The gauge-glass is not fixed directly to the boiler, but to a brass column known as the gauge-column, communicating with the boiler by two copper tubes of considerable length, the upper leading to the steam space and the lower to the water space. These tubes are fitted with cocks or valves. Two gauge-glasses of different lengths are sometimes fitted to the one column. Gauge-cocks are used as checks on the water-gauges. There are usually three of them on the front of the boiler, one at the normal level of the water, one above, and one below. As applied to railroads (q.v.) gauge signifies the distance between the centres of each pair of rails, which in the ordinary or narrow gauge is 4 feet 8½ inches. The broad gauge of the Great Western Railway of England was formerly 7 feet; the Irish, Indian, and Spanish gauge is 5 feet 6 inches. Special narrow gauges have been adopted for certain lines, especially for mountain and mineral lines, such as the 3 feet 6 inch Norwegian gauge. Gauge is also the name applied to various contrivances for measuring any special dimension, such as the wire-gauge, an oblong plate of steel, with notches of different widths cut on the edge, and numbered, the size of the wire being determined by trying it in the different notches till one is found which it exactly fits. The thickness of sheet-metal is tried by a similar gauge.

Gau'gengigl, Ignaz Marcel, American painter: b. Passau, Bavaria, 1856. He was a pupil of Diez and Raab at Munich, and set up a

studio in Boston, Mass., in 1879. He paints preferably interiors, introducing numerous small figures. Among his picture titles are: 'My Studio,' 'The Duel,' and 'The First Hearing.'

Gaul, gâl, **Alfred Robert,** English composer and organist: b. Norwich, England, 1837. He was chorister and assistant organist of Norwich Cathedral 1846–59 and subsequently organist of St. Augustine's Church, Edgbaston, Birmingham. He has composed an oratorio, 'Hezekiah'; the cantatas 'Ruth' (1881), 'First Psalm,' 'Ninety-sixth Psalm,' 'Holy City' (1882), a widely popular work; 'Passion Music'; 'The Ten Virgins' (1890), dedicated to the choirs of America; 'Song of Life'; 'Una'; etc.

Gaul, Gilbert William, American artist: b. Jersey City, N. J., 31 March 1855. He was a pupil of J. G. Brown, and studied at the National Academy of Design, exhibiting first there in 1872. He was elected associate in 1880 and National Academician 1882. He is a scene painter often choosing battle subjects, and has won several medals, including two at the World's Columbian Exposition 1893. Among his works are: 'Indian Girl'; 'Coquette' (1880); 'Old Beau' (1881); 'Charging the Battery'; 'News from Home' (1882); 'On the Outpost' (1883); 'On the Lookout'; 'Guerrillas' (1885).

Gaul, Gallia, the country of the Gauls which extended in the times of the Romans, from the Pyrenees to the Rhine, and on the side of Italy, beyond the Alps to the Adriatic. It was divided into Gaul on this side (the Italian side) of the Alps (Gallia Cisalpina), and Gaul beyond the Alps (Gallia Transalpina).

Gallia Cisalpina extended from the Alps to the Adriatic Sea, and consequently comprised all Upper Italy as far as the Rubicon and Macra, on account of its adoption of the Roman toga was called *Gallia Togata.* It was divided into Liguria; Gallia Transpadana; Gallia Cispadana. Liguria was inhabited by the Ligurians, Gallia Transpadana principally by the Taurinians, Insubrians, and Cenomani; Gallia Cispadana by the Boii, Senones, and Lingones, all of them nations of Gallic descent.

Transalpine Gaul was also called *Gallia Comata* in distinction from *Gallia Togata,* because the inhabitants wore their hair (*coma*) long, or *Gallia Braccata*, because, particularly in the southern parts, they wore a peculiar kind of breeches (*braccoe*). Caesar, who conquered Transalpine Gaul at a later period, found it divided into three parts: Aquitania, extending from the Pyrenees to the Garonne, chiefly occupied by Iberian tribes; Gallia Celtica, from the Garonne to the Seine and Marne; Gallia Belgica, in the north, extending to the Rhine.

The Gauls were the chief branch of the great original stock of Celts. On the whole, a great resemblance appears to have existed among all the Celts; and although they were divided into numerous tribes, there were but few branches that were perceptibly different from each other. It is probable that coming from the east, they took their way along the south side of the Danube, having the numerous nation of the Thracians in their rear and the Germans on their side; but the period of this event is so remote that we cannot even venture a conjecture in regard to it.

A too great population (which is not uncommon in half savage and partly nomadic nations whose means of supplying their wants are very imperfect, and who require a great extent of country), and the pressure of German and Thracian tribes, caused general migrations among the Gauls about 397 B.C. Colonies from many tribes took their course over the Alps into Italy, and eastwards along the Danube. This passage of the Celtic Gauls over the Alps first brings that nation into the region of history.

Our accounts of the course of the eastern Gauls along the banks of the Danube are very imperfect; this, however, is evident, that their movements occasioned the migrations of the whole nations. One hundred years after the burning of Rome, the eastern Gauls, from 280–278 B.C., made three destructive irruptions into Macedonia and Greece, which had already been depopulated by former wars. Ptolemy Ceraunus, king of Macedonia, and Sosthenes, the commander of the army, fell in battle, and Greece trembled. But in an attack on the temple of Apollo at Delphi (which contained immense treasures, but was protected by its situation) the terrors of religion and the assaults of the elements (tempest and hail-storms) came over them; they were defeated, and hunger, cold, and the sword of the Greeks completed their destruction. Several tribes pursued their course into Asia Minor, where, under the name of Galatians, they long retained their national peculiarities, and preserved their language even to the latest period of the empire. The reaction of these migrations upon Gaul itself appears to have been considerable. The Gauls along the banks of the Danube and in the south of Germany disappear from that time. Tribes of German origin occupy the whole country as far as the Rhine, and even beyond that river. The Belgæ, who were partly German, occupied the northern part of Gaul, from the Seine and Marne to the British Channel and the Rhine, from whence colonists passed over into Britain, and settled on the coast districts. The Celtæ in Gaul, attained a higher degree of cultivation, to which probably their intercourse with the Greeks in Massilia (Marseilles), whose letters they used in writing their own language, and with the Carthaginians, in whose armies they frequently served as mercenaries, contributed in a great measure. But they were then hardly able to resist the Germans who lived on the other bank of the Rhine. Their kinsmen, the Britons, who painted their bodies, fought from chariots, and practised polygamy, were more fierce than the Gauls.

Meanwhile the Gauls of Cisalpine Gaul had taken up their residence in the fertile plains of Upper Italy. Rome trembled at the irruption of these barbarians into Italy; but Caius Marius saved the republic. In two bloody battles, at Aix (Aquæ Sextiæ) in 102, and at Vercelli in 101 B.C., he destroyed these nations. Only that portion of them which had remained in Gaul to await the issue of the expedition escaped the general ruin. Forty-three years after this event Caius Julius Cæsar received the proconsulship over the countries bordering on Gaul.

He resolved to subject all Gaul, and executed his purpose in less than nine years (58-50 B.C.), in eight bloody campaigns.

The religion of the Druids, being suppressed in Gaul by Tiberius and Claudius, gradually retreated into Britain, where, particularly on the small islands near the British coasts, the priests established their mysterious rites, of which in ancient times strange and dreadful accounts were current. The Britons also were soon conquered by the Romans. After the extinction of the family of the Cæsars, the Gauls once more made an attempt to recover their liberty by the aid of the Germans, but in vain. After this last effort they gradually became Roman citizens, and so entirely Romanized that even their ancient language, the Celtic, was supplanted by a corrupt Latin dialect, retaining, however, a considerable number of Celtic words, especially as roots, which, intermingled with Franco-Germanic words, formed the modern language. About the year 486 the Franks subdued the greater part of Gaul, and put a period to the dominion of the Romans in that country.

Gauley Bridge, W. Va., an important strategical point at the head of Kanawha Valley, and one of the three passes of the Alleghanies. It was the objective point of Gen. Cox in his campaign from the Ohio in July 1861, and was occupied by him and strongly fortified after he had driven Gen. Wise from the valley and eastward to Lewisburg. After the battle of Carnifax Ferry (q.v.) Rosecrans advanced to Sewell Mountain, confronted Gen. Lee, who had assumed command of the Confederate forces, for several days, and then fell back to Gauley Bridge disposing the greater part of his army from 5 to 12 miles in front of it, along the Lewisburg road. With Lee's assent Gen. Floyd, with about 5,000 men, crossed New River and moved down its south side to Cotton Hill, a bold height in the angle formed by the junction of the New and Gauley rivers. He got artillery in position commanding Gauley Bridge, the ferry across the Gauley, and the road leading to Rosecrans' camps. On the morning of 1 November the artillery opened fire, sunk the ferryboat and, with sharpshooters beyond New River, stopped the passage of Rosecrans' supply-trains. The contest on both sides, with artillery and musketry, across the narrow river was severe, and ended only by darkness. The next day it was resumed and continued for ten days, the trains moving only by night. Meanwhile Rosecrans was preparing to capture Floyd by moving a force on his left and rear, a movement in which Cox, who was in command at Gauley Bridge, was to co-operate. On the 10th Cox crossed his brigade in boats over New River, at and near its mouth, and drove Floyd from Cotton Hill, after a sharp fight of two days. The co-operative movement on Floyd's left and rear failed. Floyd became aware of it, and on the 12th retreated as rapidly as possible, abandoning wagons and supplies, and pursued as far as Fayetteville. He continued his retreat to Dublin, on the Virginia and Tennessee Railroad.

E. A. Carman.

Gauley Mountains, W. Va., a range in Kanawha and Fayette counties, extending eastward for about thirty miles, from the Kanawha River near Charleston, and divided near the middle into two ridges between which flows the Gauley River.

Gauley River, W. Va., an affluent of the Great Kanawha River. It rises in the Black Mountains in Pocahontas County, and after a course of 75 miles, first westward between the Gauley Mountains (q.v.), then southward, joins New River which, from the point of junction at Gauley Bridge, is called the Great Kanawha.

Gault, gâlt (originally a local name in Cambridgeshire, England, for clay), one of the subdivisions of the Cretaceous system (q.v.). The gault is a stiff, bluish-gray clay, which here and there contains indurated nodules and septaria. Now and again it becomes somewhat calcareous, or sandy and micaceous. In some parts of Sussex a band of phosphatic nodules occurs at its base. The deposit is of variable thickness — reaching in some places over 300 feet, while occasionally it hardly attains a greater thickness than 50 feet, and forms a well-marked geological horizon — forming the bottom member of the Upper Cretaceous rocks. It is abundantly fossiliferous, the remains being almost exclusively marine, only a few drifted land-plants having been met with. The gault is extensively employed in the manufacture of bricks and tiles; it forms a retentive and rather unproductive soil.

Gaulthe'ria. (named for Dr. Gaultier of Quebec), a large genus of evergreen shrubs, or under-shrubs, with small, axillary, nodding flowers, white, pink or red, having a corolla and calyx with five divisions, the former urn-shaped or companulate; and a berry-like fruit, red or blackish, consisting of a fleshy calyx enclosing a capsule. There are about 100 species, found mostly in the Andes, a few being Asiatic and North American. Of the latter, the best known is *G. procumbens,* the familiar aromatic or creeping wintergreen, known in different localities as checkerberry (a name sometimes applied to *Mitchella repens*), boxberry, spice-berry, ground-berry, mountain tea, and partridge-berry (q.v.). This plant is found in cool, damp woods, chiefly under the shade of evergreens, in Canada and the United States, extending southward along the Alleghanies. The leaves are mostly clustered at the top of branches rising from creeping stems; the flowers are white, the berries red and spicy, with a flavor (also characterizing the leaves) resembling sweet birch. The leaves of *G. procumbens* and *G. hispidula* contain an aromatic oil which has a greater density than any other essential oil. It contains about 10 per cent of a terpene called gaultherilene and about 90 per cent of methyl salicylate. Oil of wintergreen is colorless when fresh, but later becomes yellowish, and is used for flavoring candy and for disguising the taste of unpleasant medicines. This oil may be extracted from a few other plants, particularly sweet birch (*Betula lenta*). See Wintergreen.

Gaur, gowr, a very large, fierce, and untamable ox (*Bos gaurus*) found in the forests of India and Burma, called «bison» by Anglo-Indian sportsmen, and distinguished by the Malays into two varieties called «sladang» and «sapio.» Old bulls are sometimes six feet high at the shoulders, making them the largest of wild oxen. The horns spread laterally and curve

upward to the length ordinarily of 20 to 30 inches, and are large and flattened, while the ridge of the forehead between them leans forward decidedly and is covered with a mop of gray hair. The general color is smooth, shining, blackish brown, with the feet white. This magnificent animal, which is semi-domesticated to some extent in northern India and never in the south, wanders about the jungles in small shy herds under the leadership of a powerful bull, as is the habit of forest oxen generally. It is one of the foremost objects of rifle sport in India, and the best accounts of its habits are to be found in the books of sportsmen-writers, such as Baker, Kinloch, Shakspear, Hornaday, etc. The animal must be followed on foot, in which the aid of good trackers is essential; and when it has been overtaken it is usually hidden in some dense cover, whence it is likely to charge without warning. Its flesh is excellent. See GAYAL.

Gauss, Karl Friedrich, kärl frēd'rĭн gows, German mathematician: b. Brunswick 30 April, 1777; d. Göttingen 23 Feb. 1855. At 18, while a student at Göttingen, he solved a problem (that of the division of the circle into 17 equal parts) which had occupied geometers from the time of Euclid. In 1801 was published his 'Disquisitiones Arithmeticæ,' treating of indeterminate analysis or transcendental arithmetic, and containing, in addition to many new and curious theorems, a demonstration of the famous theorem of Fermat, concerning triangular numbers. He calculated, by a new method, the orbit of the newly discovered planet Ceres, and afterward that of Pallas, for which he received from the French Institute in 1810 the medal founded by Lalande. In 1807 he became professor of mathematics and director of the observatory at Göttingen, a position which he held till his death. In 1821, being charged by the government of Hanover with the triangulation of that country and the measurement of an arc of the meridian, he rendered the most distant stations visible by means of the heliotrope, an instrument of his invention for reflecting solar light; and in connection with Weber made valuable investigations concerning terrestrial magnetism. He was pronounced by Laplace to be the greatest mathematician in Europe. Among the more celebrated of his works are 'Theoria Motus Corporum Cœlestium' (1809); 'Intensitas Vis Magneticæ Terrestris' (1833); 'Dioptrische Untersuchungen' (1841); and 'Untersuchungen über Gegenstände der höheren Geodesie' (1844).

Gautama, gow'ta-ma, or **Gotama,** the patronymic of several celebrities connected with Hindu Vedaism, and of Siddartha Gautama, the founder of Buddhism. See BUDDHA.

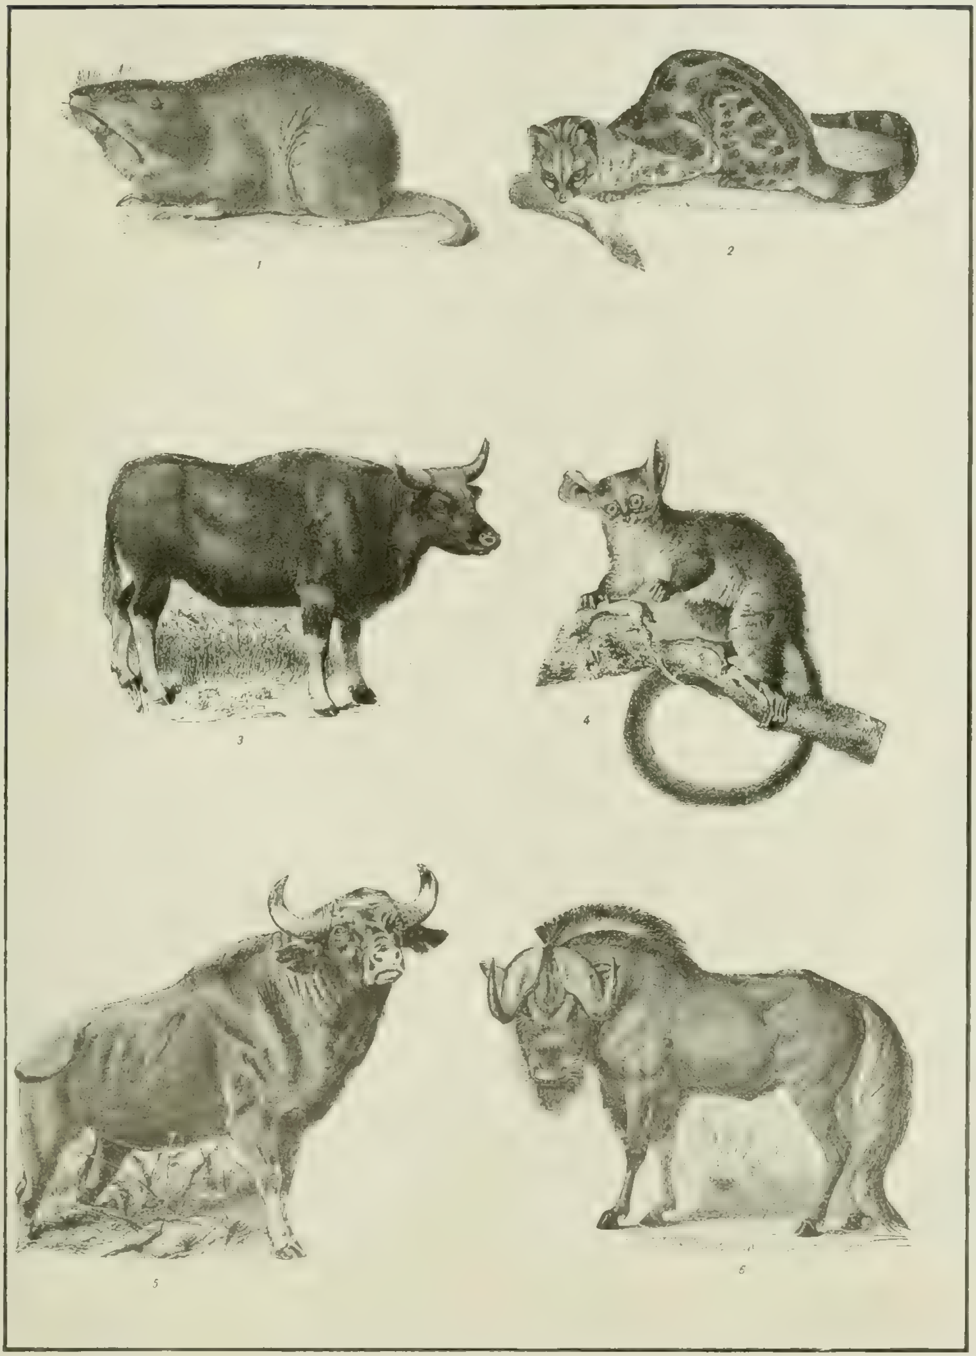
Gautier, Emile Théodore Léon, ā-mēl tā-ō-dōr lā-ôn gō-tē-ā, French scholar and critic: b. Havre 8 Aug. 1832. He held official positions connected with the schools and libraries of his native place till his growing eminence as a writer brought him to Paris. His works, which place him among the very foremost authorities on mediæval European literature, include: 'Definition Catholique de l'Histoire' (1860); 'Benoit II.' (1863); 'Etudes litteraires pour la defense de l'Eglise' (1864); 'Epopées françaises' (1866–7); 'Vingt nouveaux portraits' (1878); 'La Chevalerie' (1884); 'Histoire de la poésie religieuse dans les cloîtres des IXe et XIe siècles' (1888); 'Etudes et tableaux historiques' (1890).

Gautier, Judith, zhü-dēth, **French novelist,** daughter of Théophile Gautier (q.v.) and Carlotta Grisi, the famous Italian singer: b. Paris, France, 1850. She married Catulle Mendès, but was divorced. Her first work, under the name "JUDITH WALTHER," was 'The Book of Jade' (1867), a collection of prose and verse translated from the Chinese; it was followed by 'The Imperial Dragon' (1869), a Chinese romance, signed "JUDITH MENDÈS"; 'The Usurper,' a Japanese romance, crowned by the French Academy in 1875; 'Lucienne' (1877); 'The Cruelties of Love' (1878); 'Isoline' (1881); 'Poems of the Dragon Fly' (1884), adapted from the Japanese; 'Potiphar's Wife' (1884), a Persian romance; 'The Merchant of Smiles' (1888), a drama adapted from the Chinese; 'The Marriage of Fingal' (1888), a lyric poem.

Gautier, Théophile, tā-ō-fēl, French poet and prose writer: b. Tarbes, France, 31 Aug. 1811; d. Paris, 23 Oct. 1872. He was educated at the grammar school of his native town, and afterward at the College Charlemagne in Paris. He applied himself at first, but without much success, to painting; and then turned to literature. In verse he published: 'Albertus' (1830); 'Comedy of Death' (1832); 'Enamels and Cameos' (1856); his best poetry; etc. His novels and short stories include: 'Young France' (1833); 'Mademoiselle de Maupin' (1835); 'Fortunio' (1838); 'A Tear of the Devil' (1839); 'Militona' (1847); 'The Tiger's Skin' (1852); 'Jettatura' (1857); 'Captain Fracasse' (1863); 'Handsome Jenny' (1865); 'Spirite' (1866); etc. He was drawn early to feuilleton writing, and for more than 30 years contributed to the Paris newspapers criticisms on the theatre and the salon. He also wrote: 'Journey in Spain' (1843); 'Zigzags' (1845); 'Constantinople' (1854); 'Journey in Russia' (1866); etc., which rank among the most delightful books of modern travel. Still other works were an enlarged edition of 'Enamels and Cameos' (1872); 'The Grotesques' (1844); 'History of Dramatic Art in France' (1859); 'Balzac' (1858); 'Private Menagerie' (1869), biographical: 'History of Romanticism' (1872); 'Literary Portraits and Souvenirs' (1875); 'The East' (1877), the last two being posthumous. Gautier's whole philosophy is a philosophy of paradox, his ideal of life hardly more than a picturesque viciousness. His besetting sin was a desire to say something clever and wicked to shock the Philistines. See lives by Feydeu (1874); Bergerat (1878); Richet (1893); Brunetière, 'Evolution de la poésie lyrique' (1894).

Gauze, a light, transparent silk stuff, or sometimes a fabric of silk and cotton or silk and hemp, or of other material. In weaving gauze, at every third cast of the shuttle the warp-threads are turned or twisted after receiving the woof from right to left, and the reverse, alternately, between each throw of the shuttle, so that the weft-threads are separated from each other, the slight texture being thus produced. Gauzes are either plain or figured. The latter are worked with flowers of silver or gold, on a silk ground, and are chiefly made in China. For antiseptic purposes, etc., cotton

GAUR, GENET, ETC.



1. Gopher (Geomys bursarius).
2. Genet (Viverra genetta).
3. Gayal (Bos frontalis).
4. Galago (Otolicnus galago).
5. Gaur (Bos gaurus).
6. White-tailed Gnu (Connochætes gnu).

gauze is specially made for the use of surgeons. Special fabrics to which the name is given are also manufactured to be made into light underwear. The term has further been extended to any slight open material, as bolting-cloth and wire-cloth for various purposes. A wide-meshed, unsized cheese-cloth, which is called gauze, is considered by surgeons to be the cheapest and most convenient material for dressing wounds, being comfortable and absorbing fluid without disagreeable matting.

Gavarnie, Cascade de, France, a waterfall in the Cirque de Gavarnie, Pyrenees. It is the second highest in Europe, being 1,385 feet in height.

Gavarnie, Cirque de, France, a natural amphitheatre in the Pyrenees. It is 2¼ miles in width and 5,380 feet in height.

Gavazzi, gä-vät'sē, **Alessandro,** Italian reformer: b. Bologna, Italy, 21 March 1809; d. Rome, 9 Jan. 1889. At 16 he became a monk of the Barnabite order, and subsequently was appointed professor of rhetoric at Naples, where he speedily acquired a reputation as an orator. On the ascension of Pius IX. to the papal chair, he devoted himself to the diffusion of political enlightenment and patriotic aspirations among the masses of the Roman population. Later he forsook the papal ranks and to Gavazzi's fervid and patriotic oratory may be attributed, in no slight degree, the universal spirit of self-sacrifice evoked throughout Italy during this period of her history. He was called Peter the Hermit of the national crusade. On the establishment of the republic at Rome he was appointed almoner-in-chief to the national army. Rome having fallen, Gavazzi went to England, where he delivered numerous addresses and lectures illustrative of the political and religious aims of his country. He twice visited the United States. He was the founder of the Free Christian Church of Italy in 1870, and author of 'Recollections of the Last Four Popes' (1859); 'No Union with Rome' (1871), etc.

Gaveston, găv'ĕs tŏn (Fr. gä-vĕs-tôṅ), **Piers,** favorite of Edward II., king of England: d. 19 June 1312. He was a Gascon by birth, and on account of his father's services to Edward I. was chosen companion to the Prince of Wales, over whom he acquired a complete and very mischievous ascendency, wasting his resources, and breeding dissension between him and his father. Edward I. banished him in 1307, but died the same year, and Edward II. at once recalled him, made him Earl of Cornwall, and gave him in marriage his niece, Margaret de Clare. Intoxicated with his elevation and honors Gaveston became intolerably insolent and exasperated the nobles. He was again banished, again recalled, and, the barons having declared war, was captured, and executed near Warwick.

Gavial, gā'vĭ-al, or **Ghavial,** the common crocodile of northern India (*Gavialis gangeticus*), characterized by its greatly prolonged and slender snout, a peculiarity which increases with age and varies according to sex. In the male the nose is very much swollen, and can be inflated like a bag when the nostrils (at the extremity) are closed. The teeth are very numerous,— usually more than 100. The cranial structures accompanying these peculiarities indicate a separate family (*Gavialidæ*), which first appears in the Upper Cretaceous, and has had many fossil genera and species, among them an Asiatic monster (*Rhamphosuchus crassidens*) of the Pliocene which was 50 feet in length. The gavial inhabits chiefly the basins of the Ganges, Indus and Brahmaputra, and reaches a length of 20 to 25 feet. In the Ganges it is of a deep sea-green color above, with numerous irregular brown spots, smallest and thickest about the jaws, and below pale yellowish white. It feeds on fish and is harmless, in spite of its huge size. Its habits are little known; and still less is known of a closely related but smaller gavial (*Tomistoma schlegeli*) of Borneo, and Sumatra.

Gavotte, ga-vŏt, or **Gavot,** originally a dance of the Gavots or people of the Gap, department of the Upper Alps in France. It was a peasant dance, not unlike a minuet, and happily uniting liveliness with dignity. It was popular from the 16th to the 18th century, and at one period was in favor at court. After undergoing modifications it fell into disuse. The name is also given to a kind of music at first intended for such a dance. It came into great favor and was a frequent movement in suites, sonatas, etc., having been used by Bach and other great composers. In our time it has again become popular.

Gay, Delphine. See GIRARDIN, MADAME DE.

Gay, Edward, American painter: b. Dublin, Ireland, 1838. He came to the United States in 1838, studied art in Albany, N. Y., and as a pupil of Schirmer and Lessing at Carlsruhe; established a studio in New York; and was elected an associate of the National Academy of Design in 1868. In 1887 he obtained the Metropolitan prize for his picture 'Broad Acres,' now in the Metropolitan Museum, New York. His works have been prominent in exhibitions of the Water Color Society and the National Academy, and include: 'Washed by the Sea'; 'The Suburbs'; 'Where Sea and Meadow Meet' (Executive Mansion, Albany); 'The Waving Grain,' etc.

Gay, John, English poet: b. Barnstaple, Devonshire, England, baptized 16 Sept. 1685; d. London 4 Dec. 1732. In 1713 he published his 'Rural Sports,' which he dedicated to Pope. This compliment introduced them to each other, and proved the foundation of a friendship which lasted for life. In 1714 his caricature of Ambrose Philips' pastoral poetry was published under the title of 'The Shepherd's Week.' His pleasant mock-heroic poem, entitled 'Trivia, or the Art of Walking the Streets of London,' was published in 1715, and in that year also was acted his burlesque drama of 'What d'ye Call It?' followed by a farce, in conjunction with Pope and Arbuthnot, called 'Three Hours after Marriage.' The production of this play altogether failed. In 1720 he published his poems by subscription, in 1723 his tragedy, 'The Captives,' and in 1726 his well-known 'Fables.' His 'Beggar's Opera' was first acted in 1727 at Lincoln's Inn Fields, where it ran for 63 nights, but the lord-chamberlain refused to license for performance a second part entitled 'Polly.' The latter part of his life was spent in the house of the Duke of Queensberry, where he wrote his sonata 'Acis and Galatea' and the opera 'Achilles.' He was interred in Westminster

Abbey, where his monument bears a flippant epitaph taken from one of his letters to Pope. Among his smaller pieces, his two ballads of 'Black-eyed Susan' and ''Twas when the Seas were Roaring,' are much admired.

Gay, Sidney Howard, American journalist and author: b. Hingham, Mass., 22 May 1814; d. New Brighton, Staten Island, N. Y., 25 June 1888. Unwilling to take the oath to support the Constitution of the United States, which fostered and protected slavery, he gave up a legal career and devoted himself to anti-slavery journalism and lecturing. He became, in 1842, editor of 'The Antislavery Standard,' a position he retained till he joined, in 1857, the editorial staff of the New York *Tribune*, of which he was managing editor 1862–6. From 1867 to 1871 he occupied the same position on the Chicago *Tribune*, and for another two years was managing editor of the *Evening Post*. He was the author of Bryant & Gay's 'Popular History of the United States,' and in 1884 wrote the life of James Madison in the 'American Statesmen' series.

Gay, Walter, American artist: b. Hingham, Mass., 22 Jan. 1856. He is a nephew of S. H. Gay (q.v.), and W. A. Gay (q.v.). At 20 he went to Paris, where he studied art under Bonnat, and he has been a frequent exhibitor at the salon. Among his paintings, which have won many medals, are 'Benedicite,' now in the Museum of Amiens, France, 'Las Cigarreras' ('The Cigarette Sellers') in the Luxembourg, Paris; and canvases in the Metropolitan of Fine Arts, New York, the Museum of Fine Arts, Boston, and several noted collections in Europe.

Gay, Winckworth Allan, American artist: b. Hingham, Mass., 18 Aug. 1821. At an early age he became a pupil of Weir, professor of drawing at West Point, subsequently went to Europe, and passed five years there in study, a part of the time under Troyon in Paris. He paints exclusively in landscape. 'A Scene in the White Mountains,' a picture painted for the Boston Athenæum, is a good specimen of his method of treatment of mountain scenery. Some of his best works depict that region. But he has also painted views of Nantasket beach and rocks, which have attracted much attention, and some critics have pronounced coast scenery to be his proper specialty.

Gay-Lussac, Joseph Louis, zho-zĕf loo-ē gā-lü-säk, French physicist: b. St. Leonard, Haute-Vienne, France, 6 Dec. 1778; d. Paris 9 May 1850. In 1804 he was the first to make balloon ascensions for purposes of scientific investigation; became a member of the society of Arcueil, and was introduced to Humboldt, with whom he prosecuted an investigation of the polarization of light and other subjects. He also devoted much of his time to the study of chemistry, and to him we are indebted for the discovery of the hydro-sulphuric and oxy-chloride acids. In 1830 he became a member of the Chamber of Deputies, and in 1839 was created a peer of France. He enjoyed several official appointments, and was professor of chemistry at the Jardin du Roi.

Gay Head, a promontory and lighthouse on the western extremity of Martha's Vineyard, Mass. Lat. 41° 21′, lon. 70° 50′ W.

Gay-Lussite, gā'lŭ-sīt, a native hydrous carbonate of calcium and sodium, Ca CO_3. $Na_2CO_3 + 5H_2O$. It was described by Boussingault from crystals found in a bed of clay in the bottom of a lake near Maracaibo, Venezuela. These are vitreous, white, monoclinic prisms, having a hardness of 2 to 3 and a specific gravity of about 1.94. It also occurs in the waters of a lake near Ragtown, Nevada. It was named after the French chemist, Gay-Lussac. The name «natrocalcite» has been applied to pseudomorphs of calcite, which were supposed to be after gaylussite, but which now seem proven to be after celestite.

Gaya, gī'ä, India, chief town of a district of the same name in Bengal. It is a place of the greatest sanctity, from its associations with the founder of Buddhism, and is annually visited by about 100,000 Hindu pilgrims, who pray for the souls of their ancestors at the 45 sacred shrines within and without the walls. In Gaya proper the Brahmans reside; adjoining is Sahibganj, the trading and official quarter. Six miles south is the village of Buddha-Gaya, the home of Buddha. (See BUDDHISM.) Pop. (1901) 80,383 for the district; city 15,000.

Gayal, gī'al, or **Mithan,** a tame ox (*Bos frontalis*) of northwestern India and the hilly regions of Indo-China, known principally in the herds of the semi-civilized hill-tribes, but which also exists wild in Tenasserim. These cattle are kept for the sake of their beef, gayals never being put to any sort of work, as are humped cattle. This ox is somewhat smaller than the gaur (q.v.), has proportionately shorter legs, rounder and shorter horns, a flatter forehead and greater dewlap. It will interbreed with the gaur and various other bovine species.

Gayarré, gā-ä-rā', **Charles Etienne Arthur,** American lawyer and historian: b. New Orleans, La., 9 Jan. 1805; d. 11 Feb. 1895. He was admitted to the bar in 1829; was several times a member of the Louisiana legislature; deputy State attorney-general (1831); secretary of state of Louisiana (1846–53). Among his works, which deal largely with the history of his native State, are: 'History of Louisiana,' in French (1830); 'Louisiana, its History as a French Colony' (1851); 'Philip II. of Spain' (1866); 'Fernando de Lemos,' a novel (1872).

Gay'ler, Charles, American playwright: b. New York 1 April 1820; d. Brooklyn 28 May 1892. He removed to the West, was a law pupil of Abraham Lincoln, was admitted to practice, in 1848 edited the Cincinnati *Evening Dispatch*, and in 1850 became connected with the New York press, to which he contributed for many years. He wrote for English and American production a large number of plays, according to some statements nearly 400. These include: 'The Heir of Glen Avon,' his earliest attempt, produced in 1839; 'Taking the Chances'; 'Olympiana'; 'The American Cousin at Home' (for E. A. Sothern); 'Night and Morning'; 'With the Tide'; 'Brom Bones'; 'The Connie Soogah'; 'Bull Run'; 'Inflation'; 'Lord Tatters, Irish'; and 'Fritz, our Cousin German,' his most successful work, written for J. K. Emmet and first produced at Buffalo, N. Y., in 1869

Gayley, Charles Mills, American educator: b. Shanghai, China, 22 Feb. 1858. He was

graduated at the University of Michigan in 1878, and became professor of the English language and literature in the University of California in 1889. His publications include: 'Songs of Yellow and Blue'; 'Guide to Literature of Æsthetics'; 'English in Secondary Schools'; 'Classic Myths in English Literature'; etc.

Gaynor, William Jay, American jurist: b. Whitestown, Oneida County, N. Y., 1851. He was for a time a journalist, studied law and in 1875 was admitted to the bar, wrote on legal subjects, and was identified with many cases of importance. In 1893 he was elected a judge of the State supreme court. He became best known through securing the conviction of John Y. McKane of Gravesend for election frauds.

Gayoso, José Brunetti, hō-sā' broo-nĕt'tē gī-yō'sō, DUKE OF ARCOS, Spanish diplomat: b. Madrid, 6 Feb. 1839. He was educated at the University of Madrid, was admitted to the bar, entered the diplomatic service in 1864, and was secretary of legation at various capitals. He became minister plenipotentiary to Bolivia in 1881, to Uruguay in 1889, Chile in 1893, and Mexico in 1898. In 1899 he was appointed Spanish envoy extraordinary and minister plenipotentiary to the United States.

Gaza, gä'zä, **Theodorus,** Greek scholar: b. Thessalonica, Macedonia, about 1400; d. Italy 1478. He fled about 1444 before the Turks to Italy, where he became teacher of Greek at Ferrara, next of philosophy at Rome. Gaza has been warmly praised by subsequent scholars, such as Politian, Erasmus, Scaliger, and Melanchthon. His principal work was a Greek grammar in four books, first published by Aldus Manutius at Venice in 1495. He translated into Latin portions of Aristotle, Theophrastus, St. Chrysostom, Hippocrates, and other Greek writers.

Gaza, gā'za, Syria, an ancient town, capital of the district of the same name, about 3 miles from the mouth of the river Gaza, 50 miles from Jerusalem, on the high road between Egypt and Damascus. The bazaar and markets are of considerable importance. Gaza is a depot for barley, and has many potteries. The district of Gaza occupies the southwest corner of Syria, having the Mediterranean on the west, the valley of the Jordan and of the Dead Sea on the east, and Arabia Petræa on the south. Pop. (1900) 34,500.

Gazelle, a small antelope of the genus *Gazella,* or some related genus, exemplified by the «ariel» or «dorcas» of the Saharan and Syrian deserts, famous in poetic literature. The group contains some 25 species scattered throughout all Africa and southern Asia; and as a whole is characterized by small or moderate size, a sheep-like dentition, sandy coloration with white belly, and the usual presence of dark and light stripes on the face and flanks. The horns are of fair length, ringed, lyrate and usually present in both sexes. The gazelle (*G. dorcas*), stands about 24 inches tall at the shoulders, and has horns about 13 inches long. It is of delicate build, and extreme swiftness, leaping high as it runs, so that at full speed it seems to skim the ground like a flying bird. Its color is a light fawn upon the back, deepening into dark-brown in a wide band which edges the flanks and separates the yellow-brown of the upper portions of the body from the pure white of the abdomen. The face is marked with two stripes of contrasting colors, and the hindquarters are white. The eye of any gazelle is large, soft, and lustrous, and has been long employed by eastern poets as the most flattering comparison to that of a woman. Gazelles feed generally at dawn and at evening, and approach water only once in 24 hours. They are hunted in various ways, and their flesh is excellent. This species is becoming rare, but may still be found throughout the Sahara, and in the stony deserts of Syria. Many local names have been applied to it in books of travel and reference, most of which belong elsewhere. Such are the «korin» or «corinne» of Senegal (*G. rufifrons*); the West African «mohr» (*G. mohr*), the largest (32 inches high) and tallest of the race; the «aoul» (*G. sœmmerringi*) of Abyssinia and Somaliland, the «dama» (*G. dama*) of the Sudan, and others formerly confused with *G. dorcas.* Still other species range the plains of Central and South Africa, where some, as the springbok (q.v.), formerly assembled in vast herds, as described under ANTELOPE. Another group is formed by three similar Asiatic gazelles, — one common in Persia (*G. gutturosa*), and the others eastward, where the «goa» dwells on the high Tibetan plateau. Lastly in the Indian gazelle (*G. bennetti*), the «ravine-deer» of Indian sportsmen, we have a species with almost straight horns, which is about 26 inches tall, light chestnut in color with a blackish tail, and dwells in small bands in the dry plains along both sides of the Indus.

Gazette. *Gazzetta* was the name of a small coin once in use at Venice, and also of a kind of primitive newspaper, published there and sold for that sum. *Gazzetta,* Spanish *Gazeta,* French *Gazette,* are still used for a newspaper, but the term in England is confined to that paper of news published by authority of the government. The first 'Gazette' in England was published at Oxford 7 Nov. 1665. From that period the 'Gazette' has appeared regularly twice a week, and besides the notifications published by court and government, contains those required by law in private transactions. See NEWSPAPERS.

Gazetteer, a geographical dictionary. The first work of this kind with which we are acquainted is that of Stephen of Byzantium, who lived in the beginning of the 6th century. We have only an abridgment of it. The first modern work of the kind is the 'Dictionarium Historico-Geographicum' (Geneva 1565), by Charles Stephens, with additions by N. Lloyd (Oxford 1670, and London 1686). The works of Ferrari ('Lexicon Geographicum,' 1627) and Baudrand ('Geographia Ordine Literarum Disposita,' 1682) are full of the strangest errors. Those of Maty (1701), Thomas Corneille (1708), and Savonarola (1713) were based on the former, with additions and corrections. The 'Dictionnaire Géographique, Historique et Critique,' of La Martinière (1726), superseded all that had gone before it, though it retained many errors. The 'Geographisch-Statistisches Handwörterbuch' of the eminent German geographer Hassel (1817) was the result of laborious and judicious investigations. The 'Universal Gazetteer,' by Cruttwell (London 1808) and the 'Edinburgh Gazetteer'

(1817-22), once the principal works of the kind in English, were in course of years superseded by several others, among them Macculloch's 'Geographical Dictionary,' Blackie's 'Imperial Gazetteer' (Glasgow 1850), Lippincott's 'Pronouncing Gazetteer of the World' (Philadelphia 1855, with new editions and revisions), and Longmans' 'Gazetteer of the World.' The most valuable among European gazetteers further include the French 'Dictionnaire Géographique Universel,' Saint-Martin's 'Nouveau Dictionnaire de Géographie Universelle,' and Ritter's 'Geographisch-Statistisches Lexikon.' There are also gazetteers confined to individual States of the Union, and others to particular countries of the world.

Gears. See WHEEL GEARING.

Geary, John White, American military officer and politician: b. Mount Pleasant, Westmoreland County, Pa., 30 Dec. 1819; d. Harrisburg, Pa., 8 Feb. 1873. He was a lieutenant-colonel in the Mexican war; went to California and was appointed postmaster at San Francisco in 1849, being the first to hold that position in the city. In 1850 he was elected the first mayor of San Francisco, and in 1856 was made territorial governor of Kansas. When the Civil War broke out he enlisted in the Union army and became brigadier-general of volunteers 25 April 1862. He was in the battle of Cedar Mountain 9 Aug. 1862, and commanded a division at Chancellorsville, Gettysburg and Lookout Mountain. He also participated in Sherman's march to the sea. He was governor of Pennsylvania from 1867 till shortly before his death.

Gebhardt, Eduard von, ed'oo-ärd fōn gāb'-härt, German painter: b. St. Johannes, Esthonia, 13 June 1838. He studied at the St. Petersburg Academy in 1854–7, and later with Wilhelm Sohn at Düsseldorf, where he established his studio and attracted much attention by his religious works, in which he treated biblical scenes after the manner of the Dutch and Germans of the 15th and 16th centuries, imitating their introduction of costumes and other features contemporary to them. He also painted many scenes from the period of the Reformation. In 1873 he was appointed professor in the Düsseldorf Academy. His subjects include: 'Christ's Entry into Jerusalem'; 'The Rich Man and the Beggar Lazarus'; 'The Last Supper,' his chief work (National Gallery, Berlin); 'The Ascension,' one of his best canvases; 'Religious Conversation'; and 'The Reformer at Work.'

Geckos, gek'ōz, the small lizards of the family *Geckonidæ*, distinguished from other lizards by structural peculiarities which indicate that the group is a very ancient and distinct one. Externally their robust forms, short heads and thick, but fragile tails; the skin, in most soft and pebbled with minute bony concretions (osteoderms); the lack of eyelids, the ball of the eye being studded by a transparent watch-glass-like scale; and adhesive feet are so highly characteristic that a gecko is usually recognizable at a glance. The group consists of about 50 genera, comprising some 270 species, and they are scattered all over the warmer part of the globe, occurring even in New Zealand and many oceanic islands. Most of the species are small, the largest not much exceeding a foot. They dwell mainly in the woods, and among rocks, hiding by day, or basking quietly in the sun, and becoming active at night. They are carnivorous, the smaller eating insects, and the larger bigger insects and whatever else they can catch. They are well fitted for scrambling about tree-trunks and cliffs, as is seen in the agility of the common "tarentola," "osga" and other geckos of southern Europe, and the almost domestic "cheecha" (*Hemidactylus*) of Ceylon and India, which are numerous both outside and inside of farm and village houses, snapping up flies. They will climb a smooth wall or even a window pane without difficulty, and even run back downward along the smooth whitewashed ceiling. This is possible for them by the fact that the soles of the cushions of the toes are furnished with transverse lamellæ beset with tiny hair-like excrescences, between each two of which a vacuum is formed by the pressure of the foot on every step. Upon the differences in the arrangement of the pads and lamellæ are based generic distinctions. In addition to this facility of movement, one species (*Ptychozoön homalocephalum*), the flying or fringed gecko of the Malayan region, has a lateral parachute-like membrane assisting it to make long leaps from tree to tree.

Geckos are entirely harmless and could not inflict a painful bite if they tried; yet the peasants of Spain and Italy fear as poisonous even those which they see daily in their houses, and the Egyptians accuse them of leprosy. When encouraged they become tame and friendly and show considerable intelligence. Their voices produce a feeble clicking sound, often repeated, from which comes the term "Gecko" and such local names as "toco-toco" and the like. They reproduce by hiding among rotten wood two or three globular hard-shelled eggs, from which the young hatch, and are ready at once to begin to care for themselves. Consult Gadow, 'Amphibia and Reptiles' (1901); Gosse, 'A Naturalist's Sojourn in Jamaica' (London 1851).

Ged, William, Scottish goldsmith, inventor of stereotyping, b. Edinburgh 1690; d. there 19 Oct. 1749. In 1725 he took out a patent for his method of stereotyping, which was for long the only one in use. He met with such opposition in Edinburgh that he went to London, but there also failed to get his invention adopted. In 1731 he obtained a contract to print Bibles and prayer-books for the University of Cambridge, but only two prayer-books had been executed when the lease was surrendered. He stereotyped an edition of Sallust in 1744. Consult 'Memoir,' by Nichols (1781).

Geddes, gĕd'ĕs, **James,** American scholar: b. Boston, Mass., 29 July 1858. He was graduated from Harvard in 1880, was instructor in Romance languages at Boston University in 1887–90, assistant professor in 1890–92, and in 1892 was appointed professor. His writings include various monographs and articles for periodicals, and student's editions of Spanish and Italian classics.

Geddes, James Lorraine, American soldier: b. Edinburgh, Scotland, 1827; d. 1887. After residence in Canada, he studied in the British military academy of Calcutta, India, distinguished himself in the Punjab, and settled at Vinton, Iowa, in 1857. In the Civil War he served from 1861 to 1865, and attained the brevet rank of brigadier-general of volunteers. He

wrote: 'The Stars and Stripes,' 'The Soldier's Battle Prayer,' and other war verse.

Geefs, Gillaume, gē-yōm gāfs, Belgian sculptor: b. Antwerp 10 Sept. 1806; d. Brussels 24 Jan. 1883. He became professor at the Academy of Antwerp in 1834. Among his most important works are the monument to the victims of the Revolution of 1830 at Brussels; a statue of Rubens in front of Antwerp Cathedral; statues of King Leopold, etc.

Geefs, Joseph, Belgian sculptor: b. Anwerp 25 Dec. 1808; d. there 10 Oct. 1885. He was a brother of Gillaume Geefs (q.v.). In 1841 he was appointed professor of sculpture in the Antwerp Academy, and in 1846 became a member of the Belgian Academy. Among his principal works are: A statue of Vesalius, at Brussels; one of Martens, the first Belgian printer, at Aelst; an equestrian statue of Leopold I., at Antwerp; and 'The Fallen Angel,' in the Brussels Palace of Fine Arts.

Geelong, gē-lông', Australia, a city of Victoria, on Corio Bay, 45 miles south of Melbourne. The gold discoveries in 1851 added to its prosperity. Limestone and a kind of marble are found in the neighborhood. The industries are the manufacture of woolen cloths and paper, meat preserving, tanning, rope making, fishing, etc. The city is lighted with gas, and has two parks, botanical garden, government buildings, a town hall, hospital, chamber of commerce, mechanics' institute, etc. Corio Bay is a favorite bathing resort. Pop., including suburbs (1901), 23,440.

Geelvink (gāl'vĭnk) **Bay,** an arm of the Pacific in New Guinea. Its entrance, about 155 miles wide, is protected by several islands.

Geertz, gärts, **Julius,** German painter: b. Hamburg 21 April 1837. He was a pupil of Günther and Martin Gensler at Hamburg, of Descoudres at Carlsruhe, and of Jordan at Düsseldorf, located his studio at Düsseldorf, and established his reputation by his skilful genre scenes, of which the 'Criminal after Condemnation' was the first to win prominent notice. His works, characterized in general by excellence of design and color, fidelity of interpretation, and a capital sense of humor, include: 'The Fly-catcher'; 'Die Wacht am Rhein'; 'A Prisoner of War'; 'The Village Hero'; 'Alms.' During a visit to the United States he painted portraits of Oswald Ottendorfer, Carl Schurz, and other German-Americans.

Geese, a large group of water-birds allied to the ducks and swans, and forming with them the family *Anatidæ*. It is not possible to separate geese and ducks into two well-defined groups. Generally speaking, however, geese are distinguished by their larger size; short, heavy bill, with reduced lamellæ; longer legs, placed nearer the centre of the body; and the absence of enlargements of the bronchial tubes. Some thirty species of true geese exist, and about a dozen others are usually known by that name. Males are called "ganders," and young birds "goslings." The most typical geese are those of the genus *Anser*, represented in Europe by the gray lag (*A. cinereus*), bean-goose (*A. segetum*) and white-fronted goose (*A. albifrons*). A variety of the last occurs also in North America. The gray-lag goose is the original of the domestic races of geese. In its wild state it ranges over nearly the whole of Europe and northern Asia, and was formerly an abundant breeder on the British Isles.

The best known wild geese in America are the Canada goose (*Branta canadensis*), the brant (*B. bernicla*) and the snow-goose (*Chen hyperboreus*). The former presents several varieties differing mainly in size, the Hutchin's and cackling goose of the West being not larger than big ducks. One form or another occurs all across the continent, breeding mainly north of the United States, migrating southward in the autumn, and wintering on the coasts and inland waters, where they are regularly hunted by sportsmen. In early spring the northward flight of these geese in their customary V-shaped rank is heralded as an indication that winter is over. The brent goose or brant is a smaller darker bird, breeding far northward and occurring along our coasts often in immense numbers during the winter, and also on the coasts of Europe, being everywhere a salt-water bird. The black brant of our western coast, and the bernacle goose (q.v.) of the north of Europe, are allied species. Several species of snow-geese or laughing geese, are found in America, most plentifully in the interior. Most of them are pure white in the adult state, more or less gray during the first year; but the blue goose (*Chen cærulescens*) is always bluish gray, with the head white in the adult.

In Patagonia and the adjacent islands are several peculiar geese in which the sexes differ totally in coloration, the males being white and the females brown; some of them are strictly upland birds. The largest known goose is the Chinese swan-goose (*Cygnopsis cygnoides*), which is supposed to be the parent stock of the domestic geese of some eastern countries. The peculiar Cape Barren goose of Australia (*Cereopsis novæ-hollandiæ*), an upland goose which has lost the power of flight, has the webbing of the toes greatly reduced and the bill very short and rounded. Another curious species is the spur-winged goose of Africa (*Plectropterus rueppelli*) which possesses hornlike weapons on the bend of the wing. This is a beautiful bird bred in captivity by fanciers for ornamental service.

Domestic Geese.— The breeding of geese is followed on a large scale in some countries and was formerly extensively carried on in parts of England, where the flocks were regularly tended by a gooseherd and driven daily to pasture and water. Geese are valuable not only for their flesh and eggs, but for the plumage, and where kept for the latter purpose are plucked four or five times a year. The feathers are used chiefly for stuffing pillows, etc.; but as a result of public sentiment against the use of the plumage of wild birds in millinery, the manufacture of artificial plumes and feather-ornaments for hats is becoming an important industry, and goose-feathers form the basis of most of these fabrications. Geese are often specially fattened for the table. The liver of a fat goose is often larger than all the other viscera. The celebrated *pâtés de foie gras* of Strasburg are made of goose-livers, which are brought to a state of abnormal enlargement by keeping the birds in an apartment with a high temperature and cramming them with food. The oily fat and preserved breasts of geese are German delicacies. Six

standard varieties of domestic geese are kept in the United States, for practical purposes, as follows:

Gray Toulouse.— Derived from the neighborhood of Toulouse, France; compact in form; gray, with brown wing-quills, hazel eyes, and bills and feet deep orange; full weight, 20 pounds. They are late in maturing, and hence are often called Christmas geese; their flesh is not of the best, but they are good egg-layers. They are bred largely by farmers.

White Embden.— Large, tall, snow-white geese derived from Westphalia, weighing 18 to 20 pounds when adult; eyes blue, bills flesh-color; feet deep orange. They are highly regarded by farmers as practical birds.

Gray African.— Tall, with long necks and large heads, a large knob on the base of the bill and a heavy dewlap; general color gray, darkest on the back; eyes hazel; bill black; feet dark orange; weight, 18 to 20 pounds. These are by many raisers considered the most profitable of all geese to keep. They grow the heaviest in the shortest space of time, are ready for market in 10 weeks, and as compared with other geese give the most satisfactory returns for the least labor and time spent in growing them. They are first-class layers and their flesh is fine and nicely flavored.

Chinese Geese.— Small graceful geese in two varieties, brown and white, weighing as adults 12 to 14 pounds. In colors and the shape of the head and knobbed bill they resemble the African breed; the white variety is pure white throughout, with the bill orange instead of black. They are the most prolific layers of all the breeds, averaging 50 to 60 eggs a year; and are otherwise commendable, especially for the table.

Wild Geese.— Descendants of the American wild goose; weight 14 to 16 pounds. They are very generally bred throughout the country, and exhibit many good qualities.

Consult Weir, 'The Poultry Book' (New York, 1903).

Geezeh. See Gizeh.

Geffrard, zhĕ-frär, **Fabre,** Haitian president: b. L'Anse-à-Beau 19 Sept. 1806; d. Kingston, Jamaica 11 Feb. 1879. In 1843 he joined Gen. Hérard's insurrection against President Boyer, and as commander of Hérard's advance guard, annihilated Boyer's force at Numéro Deux. In the wars with Santo Domingo (1849, 1856) he fought with distinction, later led a successful insurrection against President Soulouque, and was president from 1859–67, when a conspiracy of Salnave, an army officer, obliged him to escape to Jamaica.

Gefle, yāf'lā, Sweden, a seaport town and capital of Gefleborg, and at the mouth of a river of same name in the Gulf of Bothnia. It stands on both sides of the river and two islands formed by it, consists of spacious and well-paved streets, and houses partly of wood and partly of stone; and has an old castle, ship-building yards, and an excellent harbor. Pop. (1900) 29,522.

The district of Gefleborg has an area of 7,614 square miles; a coast deeply indented by bays, and an interior partly mountainous and covered with pine forests, and containing a large number of lakes, which, with the streams between them, form a kind of continuous network. The rearing of cattle is the chief employment. The most valuable mineral is iron. Pop. (1900) 228,862.

Gefleborg. See Gefle.

Gehenna, gē-hĕn'ạ. See Hell.

Gehennam, gē-hĕn'ạm. See Tophet.

Gehlenite, gā'lĕn-īt (named by Fuchs after his colleague Gehlen), a grayish-green or brown tetragonal mineral; hardness 5.5 to 6; specific gravity 2.9 to 3.1; lustre resinous or vitreous; fracture uneven to splintery. It is composed of a silicate of calcium and aluminum, $Ca_3Al_2Si_4O_{10}$. This mineral has feeble double refraction. It is found in the Tyrol and in Banat, and occasionally occurs among the scoriæ of furnaces.

Geijer, gī'ĕr, **Eric Gustaf,** Swedish historian: b. Ransäter, Wermland, 12 Jan. 1783; d. Stockholm 23 April 1847. Beginning to lecture at Upsala in 1810, he was elected in 1815 assistant professor, and in 1817 professor of history at Upsala. Geijer exercised a marked influence on the poetic no less than on the historical literature of Sweden. Great as is the value of Geijer's historical works, he unfortunately did not complete any one of the vast undertakings which he planned. Thus, of the 'Svea Rikes Häfder,' or Records of Sweden (1825), which were to have embraced the history of his native country from mythical ages to the present time, he finished only the introductory volume. This, however, is a thoroughly good critical inquiry into the sources of legendary Swedish history. His next great work, 'Svenska Folkets Historia' (1832–6), was not carried beyond the death of Queen Christina. Of his other historical and political works may be mentioned 'The Condition of Sweden from the Death of Charles XII. to the Accession of Gustavus III.' (1838), and 'Feudalism and Republicanism' (1844). During the last 10 years of his life Geijer took an active part in politics; but, although his political writings possess great merit, the very versatility of his powers diverted him from applying them methodically to the complete elaboration of any one special subject. He was also known to his countrymen as a musician and composer of no mean order. His collected works were published by his son, with a biographical sketch (13 vols. 1849–56).

Geikie, gē'kĭ, Sir **Archibald,** Scottish geologist and scientific writer: b. Edinburgh 28 Dec. 1835. He entered the geological survey in 1855 and has since had a brilliant career of discovery and experiment, and held many important honorary positions. Among his publications are: 'The Story of a Boulder' (1858); 'Elementary Lessons in Physical Geography' (4th ed. 1884); 'Scenery of Scotland Viewed in Connection with its Physical Geology' (2d ed. 1887); 'Outlines of Field Geology' (4th ed. 1881); and 'Text-Book of Geology' (3d ed. 1893); 'The Ancient Volcanoes of Britain' (1897).

Geikie, James, Scottish geologist, brother of Archibald Geikie (q.v.): b. Edinburgh 23 Aug. 1839. He was educated at Edinburgh University in which he held the chair of geology in 1882. He is the author of: 'The Great Ice Age' (1874); 'Prehistoric Europe' (1882); 'Outlines of Geology' (1884); 'Fragments of Earth Lore' (1892); 'Earth Sculpture' (1898).

Geikie, John Cunningham, English Anglican clergyman: b. Edinburgh 26 Oct. 1824. He was educated at the University of Edinburgh, was pastor of Presbyterian churches in Halifax and Toronto, was ordained priest of the Established Church in 1876, and was successively curate of St. Peter's, Dulwich, 1876–9; rector of Christ's Church, Neuilly, Paris, 1879–81; vicar of St. Mary's, Barnstaple, 1883–5; and vicar of St. Martin-at-Palace, Norwich, in 1885–90. His publications include: 'The Life and Words of Christ' (1876); 'Old Testament Characters' (1880); 'The English Reformation' (1884); 'Landmarks of Old Testament History' (1895); 'A New Short Life of Christ' (1898); 'The Vicar and His Friends' (1901).

Geisha, gā'sha, a Chino-Japanese word, meaning "one with pleasing accomplishments," applied to Japanese singing and dancing girls who furnish entertainment in tea-houses and at social gatherings.

Geissler, Heinrich, hīn'rĭH gīs'lĕr, German mechanician: b. Igelshieb, Germany, 26 May 1814; d. Bonn, Prussia, 24 Jan. 1879. He became known as a maker of physical and chemical apparatus and principally as the inventor of Geissler's tubes (q.v.), an apparatus for producing light by an electric discharge in vacuo.

Geissler's Tubes, tubes made of very hard glass, and containing highly rarified gases. Each end of the tube has a platinum wire sealed into it to serve as electrodes. When a discharge of electricity is caused to take place in these tubes by connecting the electrodes to the terminals of a Ruhmkorff's coil or a Holtz's machine, very brilliant effects may be produced. The invention was named after Heinrich Geissler (q.v.).

Gela, jē'la, Sicily, a city of ancient Greece, situated on the island between Agrigentum and Camarina; founded in 690 B.C. by the Cretans and Rhodians. The colony was remarkably prosperous, and in 528 B.C. sent out a portion of its inhabitants, who founded Agrigentum. In 280 Phintias, the tyrant of Agrigentum, utterly destroyed Gela.

Gelada, gĕl'a̤-da̤, a kind of baboon (q.v.).

Gelasius (jē-lā'sĭ-ŭs) **I., Saint,** Pope: d. 19 Nov. 496. He succeeded Felix III. on 1 March 492. At the Council of Rome in 496 he distinguished the canonical books from the apocryphal of Scripture. He also regulated the canon of the Mass. He was succeeded by Anastasius II.

Gelasius II. (Giovanni di Gaeta, jō-vän'nē dē gä-ā'tä), Pope: d. Cluny, France, 29 Jan. 1119. He was cardinal and chancellor under Urban II. and Paschal II., and on the death of the latter was chosen pope by the party hostile to the Emperor Henry V. The imperial party at Rome under the Frangipani seized his person, but were forced to set him free by the menacing attitude of the mob. The new pope fled before the advancing imperial troops to Gaeta, where he first received his consecration, and whence he excommunicated Henry V. and Gregory VIII., the antipope Henry had set up. Soon after he was able to return to Rome, but ere long had to betake himself for protection to France, where he died in the monastery of Cluny.

Gelatine, jĕl'a̤-tĕn, or **Gelatin** (Latin, *gelatus*, "frozen," so named from the tendency which the substance has to congeal and become to a certain extent solid), in chemistry $C_{75}H_{124}N_{24}O_{29}$ (?). Animal glutin, obtained by treating bones with dilute hydrochloric acid, which dissolves the mineral constituents of the bone, consisting of phosphates and carbonates of calcium, magnesium, etc., and leaves the bone cartilage. This, when boiled for a long time with water, dissolves, and forms gelatine, which can be purified by dissolving in hot water and precipitating by alcohol. A pure variety is obtained from the swimming bladder of the sturgeon. Impure gelatine glue is prepared by boiling down pieces of hide, horn, hoof, cartilage, etc., with water under pressure. Pure gelatine is amorphous, transparent in thin plates, of a yellowish-white color; it has neither taste nor smell, and is neutral to vegetable colors; it is insoluble in alcohol and in ether. In contact with cold water it swells up, and is soluble in hot water. It is not precipitated by acids, except by tannic acid, which gives a flaky precipitate insoluble in water, alcohol, and ether. The aqueous solution of gelatine turns the plane of polarization to the left. Gelatine subjected to dry distillation yields methylamine, cyanide of ammonium, pyrrhol, etc.; by oxidation with sulphuric acid and manganese dioxide, or with chromic acid mixture, it yields hydrocyanic acid, acids of the fatty series, benzoic aldehyde and benzoic acid, etc. Gelatine boiled with caustic potash yields glycocine and leucine. Gelatine contains about 50 per cent. of carbon, 6.6 of hydrogen, and 18.4 of nitrogen. Moist gelatine exposed to the air rapidly putrefies, the liquid becoming first acid, but afterward it gives off ammonia. Gelatine gives no precipitate with lead acetate, alum, or ferrocyanide of potassium. A mixture of gelatine with potassium dichromate becomes, when exposed to the action of light, insoluble in water. The nutritious value of gelatine has been much overestimated. Isinglass is prepared from the form derived from the sturgeon's bladder; and gelatine is also made use of in photography (q.v.).

Gelatine Process. See PHOTOGRAPHY AND PHOTO-ENGRAVING.

Gelderland, Hĕl'dĕr-länt, or **Guelderland,** a province of Netherlands, with the Zuyder Zee on its northern boundary. Area, 1,965 square miles. The surface is level, the soil of the north sandy, the southern part low, marshy, but when cultivated, fertile. The principal rivers are the Rhine and the Meuse. The capital is Arnhem (q.v.). (For history see NETHERLANDS.) Pop. 567,489.

Gelée, zhė-lā, **Claude.** See CLAUDE LORRAINE.

Gelert, Johannes Sophus, American sculptor: b. Schleswig, Denmark, 10 Dec. 1852. He studied in the Royal Academy of Fine Arts at Copenhagen in 1870–5, removed to the United States in 1887, received a gold medal and honorable mention at the World's Columbian Exposition (1893), a gold medal at the Nashville Centennial Exposition (1897), and honorable mention and a gold medal at the Paris Exposition of 1900. His works include the monument to the policemen killed by the Chicago anarchists,

Haymarket Square, Chicago; statues of Beethoven and Andersen in Lincoln Park, Chicago; a statue of Grant at Galena, Ill.

Gellius, jĕl'ĭ-ŭs, **Aulus,** Roman author: b. possibly about 130 A.D. He studied rhetoric at Rome and philosophy at Athens, and practised as a lawyer at Rome. He is the author of 'Noctes Atticæ,' full of interesting observations and quotations, from the best Latin and Greek authors, relating to language, literature, history, and antiquities. This work was partly compiled in the winter nights during his residence at Athens. It is now of great value, as the authors from which he drew his materials are in a great measure lost. Among the best editions is that of Hertz (1883–5).

Gelon, jē'lŏn, tyrant of Gela and afterward of Syracuse: d. about 478 B.C. He was a scion of a noble family of the former city, and succeeded its tyrant, Hippocrates, in 491 B.C. Six years later he made himself master of Syracuse also, which then became the seat of his government, and to which he transferred the majority of the inhabitants of Gela. Gelon refused to aid the Greeks against Xerxes, as they declined to comply with his demand that he should be appointed commander-in-chief. The clemency and wisdom of Gelon rendered him so generally beloved that when he appeared unarmed in an assembly of the people, and declared himself ready to resign his power, he was unanimously hailed as the deliverer and sovereign of Syracuse.

Gelose, jē'lōs, a pectic substance containing carbon, 42.77; hydrogen, 5.775; oxygen, 51.455, prepared by Payen from a commercial article entitled Chinese moss, which consists of long white threads made up into bundles, and from various seaweeds. It is used for food, and is said to be the juice of a lichen growing on trees in the south of China and in the Philippine Islands. The moss, when boiled in water, dissolves, with the exception of 2 or 3 per cent of nitrogenized corpuscles and traces of other matter, and on cooling forms a transparent colorless jelly, which when dried constitutes gelose. It is distinguished from other bodies by certain characteristic reactions.

Gelsemium, jĕl-sē'mĭ-ŭm, yellow jasmine, the dried rhizome and roots of *Gelsemium sempervirens;* a southern climbing-shrub with a large woody underground stem and dark-green leaves, and bright, yellow sweet-scented flowers. It grows from Virginia southward in woods, and mounts to the top of tall trees. The active constituents contained in the underground stem are two alkaloids, gelsemine and gelseminine, the latter of which is the more potent. Gelsemium is an acute poison, acting both on the sensory and motor end-organs, causing anæsthesia and motor weakness. The early symptoms of large doses are loss of power in the muscles of the eye, causing drooping of the lids, dizziness, drowsiness, and disturbance of vision. In poisonous doses there is marked diminution in the force of the pulse and respiration, with difficulty of speech, coldness of the body surface and general loss of skin sensations. Death results from asphyxiation. Its most important medicinal use is in neuralgias, in sick-headache, and as a general nerve tonic.

Gemini, jĕm'ĭ-nī, the Twins (♊), the third sign of the zodiac. The sun enters this sign on or about 21 May, and leaves it on or about 21 June. The name belongs also to a northern constellation, of which the two chief stars are Castor and Pollux. They are very nearly equal in brilliancy, which fact probably suggested the name. Pollux is slightly the brighter. It is a quadruple star. Castor is one of the finest of the double stars. See ASTRONOMY.

Gemistus, jĕ-mĭs'tŭs, **Georgius.** See PLETHO, GEORGIUS GEMISTUS.

Gemmi (gĕm'mē) **Die,** Switzerland, a narrow pass, nearly two miles long, which crosses the Alps at a height of 7,553 feet, and connects the Swiss cantons of Bern and Valois.

Gemmules, jĕm'ūlz. (1) In actual biology gemmules are aggregations of cells set apart in the body of sponges and polyzoans to serve as reproductive agents. This is one of the most primitive forms of reproduction. (2) In philosophical biology gemmules are hypothetical, self-reproducing particles in the reproductive protoplasm (a structure which is assumed) supposed to be bodily transmitted from parent to child, and to carry such qualities as are inherited by offspring.

Gems are precious stones of small size, such as may be used for setting in a ring, or for any similar purpose of ornament. Like everything else of great value, precious stones have been imitated, and the practice has been carried on from the earliest times. The art of glass-coloring was known to the ancient Egyptians, who produced excellent imitations of the most beautiful gems. Among the Romans in the time of Pliny the manufacture of false stones was far advanced as a branch of industry. There existed several treatises on the subject, and Pliny declared that it was a difficult task to distinguish the false gems from the true. The alchemists of the Middle Ages, according to Aquinas, successfully fabricated artificial jewels, and he instances the jacinth, sapphire, emerald, topaz, and ruby, as being skilfully counterfeited. About the middle of the 17th century, false stones were no longer manufactured according to methods differing for each stone, but according to a general formula much the same as that followed at the present day.

Artificial Gems.— The base of all modern artificial gems is a peculiar kind of glass of considerable hardness, brilliancy, and refractive power, called paste or strass, which is distinguished from ordinary glass by the presence of 50 per cent of oxide of lead among its constituents. When the strass is obtained very pure, it is melted and mixed with substances having a metallic base, generally oxides, which communicate to the mass the various desired colors. We give a few details showing how the principal gems may be imitated. The diamond being colorless, pure strass simply cut into brilliants and roses is used as a counterfeit. The ruby is imitated by mixing 1,000 parts of strass, 40 parts of glass of antimony, 1 part purple of Cassius (a preparation of gold and binoxide of tin), and 1 part in excess of gold. Sapphires are counterfeited by 1,000 parts strass, and 25 of oxide of cobalt. Topaz — the same formula as for ruby,

without the excess of gold, and heated for a less time. Emerald, 1,000 parts of strass, 8 oxide of copper, and 0.2 oxide of chromium. Amethyst, 1,000 parts strass, 25 oxide of cobalt, and a little oxide of manganese. Garnet, 1,000 parts strass, and a variable quantity of purple of Cassius according to the shade to be obtained. In all these preparations success mainly depends upon a thorough pulverization and mixture of the ingredients; the fusion should be long continued at a graduated and uniform maximum temperature, and the mixture be annealed in cooling. These imitations, which are made in immense quantities in large factories in France and elsewhere, are chiefly used in the manufacture of cheap jewelry.

Attempts have, however, been made with a fair measure of success to manufacture true gems by artificial processes. Of these processes we need only mention that introduced by the French chemists Frémy and Verneuil. They succeeded in manufacturing excellent rubies, very like the natural ones in shape and composition, by raising carefully to a red heat a mixture of alumina, barium fluoride, and a very small quantity of bichromate of potash. The rubies are found in a friable matrix. If a little cobalt oxide be present in the mixture, sapphires are obtained instead of rubies. Many experiments with a view to producing diamonds artificially have been made within recent years. From hydrocarbons, subjected to a very intense heat and enormous pressure, minute crystals have been obtained which are as hard as the natural diamond, scratching all other minerals, and not affecting polarized light. The process is, however, expensive, tedious, and dangerous, and the diamonds produced are as yet so small that it requires more than 1,000 of them to make a carat; only ½ carat has been produced, at an expense of $2,000; hence they represent nothing beyond a scientific value. A diamond exists in the meteorite from Cañon Diablo, Arizona, in the Kunz collection at the American Museum of Natural History, New York. This is the first diamond identified in a meteorite,— by Dr. G. A. Koenig, in 1891.

We come now to genuine precious stones which will be taken up in the order of their rarity and value:

Diamonds.— The diamond, although not the rarest nor the most valuable of precious stones, is often called "the king of gems." It consists of pure carbon, crystallized in what is known as the isometric system, almost always occurring in the form of a regular octahedron or some modification thereof. It is the hardest of all known substances, ranking as ten (10) in the scale of hardness. It possesses a higher refractive and dispersive power on light than any other gem, whence arise the extreme brilliancy, and the varied flashes of color, or "fire," that give it such beauty. Being carbon, it is combustible,— the only gem that is so,— burning to carbonic acid in oxygen, or even in air under suitable treatment; this property was discovered as long ago as 1691, by Cosmo I., of Tuscany, who ignited a diamond with a burning-glass. Its density is about 3.5. In color it varies much, from white or colorless to yellow, also brown, rarely green, blue, pink, rose-red, occasionally even black. Some diamonds phosphoresce upon friction, and glow strongly under the influence of violet and ultra-violet light, and the emanations from the new and singular element known as radium, or rather from its compounds. They are absolutely transparent to the X-rays, of Roentgen. All these properties serve as ready means for distinguishing real diamonds from the best imitations. The value of a diamond depends on several conditions, chiefly size, color, and brilliancy. As to size, they are rated by the carat (or karat). This was the name of certain small seeds, which when dried, are quite constant in weight, and were used in India for weighing gems. It has now become a fixed standard for this purpose, used among all civilized nations, as the "international carat." In 1871, the syndicate of jewelers, goldsmiths, and gem-dealers of Paris proposed to fix its value at .205 of a gram; and this was generally adopted in 1877, and accepted by the principal dealers of Paris, London, and Amsterdam,— the centres of the world's diamond trade. The English carat is equal to 3.1683 grains Troy (usually reckoned as 3.17 grains); so that there are 151½ carats in an English Troy ounce. The jewelers' carat is divided into halves, quarters, eighths, sixteenths, thirty-seconds and sixty-fourths. A quarter-carat is sometimes called a grain, though it is less than a true grain; and pearls are generally sold by the grain, in this sense. As to color, the highest value belongs to perfectly white stones, or to those of fine bright tints, whether rose, green, or blue. These last are very rare and command fancy prices. Yellow diamonds are much more frequent, but when of rich color, are valuable. Any half-way tints, however, such as yellowish whites, are far less desired. Some possess a delicate steely-blue tinge, sometimes a delicate opalescence, and are called "blue-white"; these are particularly the Brazilian stones from Bagagem, and are also notable for their phosphorescent property. Perfectly colorless and flawless diamonds are spoken of as of "first water," a term which varies, however, according to the class of goods carried by the dealer using it. Many of the African stones are what is called "Cape white," that is, faintly yellowish; these are indistinguishable from pure white ones by artificial light, but command much lower prices. The finest diamonds are not found in the Kimberley mines, but in the Orange River Colony and the Transvaal. Diamonds vary also in brilliancy, some having higher lustre than others. New South Wales yields small stones that are harder than usual, and at the same time exceedingly brilliant. All these natural qualities, together with perfection of cutting, enter into the estimate of values, and may cause very great differences. Of two diamonds of ten carats each, both flawless, one may be worth $600 and the other $12,000. Exceptional stones often bring special prices. Diamonds are occasionally found in many parts of the globe, but in only a few regions are they at all frequent or large, so as to be mined for. They were first obtained in India, then somewhat in Borneo, then in Brazil; more recently they are coming from New South Wales, and lately British Guiana is yielding a number. But all other sources are insignificant compared with the wonderful diamond mines of South Africa, which furnish 95 per cent of the world's supply,

and have yielded since their discovery some 30 years ago, more diamonds than all other sources together in all past time. A few are found in Siberia, and in California; also along a line east of the Blue Ridge from Virginia to Georgia, and along another line from Wisconsin to southern Ohio; but these are only occasional, and are more interesting than important. The diamond seems to have been unknown to the ancients, outside of India, until about the beginning of the Christian era. The words rendered "diamond" in the Bible, and in classical writings prior to that time, refer to other hard minerals.

Rubies and Sapphires.— The ruby and the sapphire, transparent varieties of corundum (q.v.), the first being carmine red, and the second bright blue. Other colors also occur, as yellow, green, and purple, called respectively, Oriental topaz, Oriental emerald, and Oriental amethyst. Corundum crystallizes in the hexagonal system, and consists of alumina nearly pure. In hardness it ranks next below the diamond, being rated as 9 on the scale. The finest rubies are found in Burma, in the Mogok Valley, northeast of Mandalay. They are also mined in Siam, of a darker red, and in Ceylon, of a lighter shade. The Burmese rubies have a peculiar tint, called "pigeon's blood." Sapphires come principally from Siam and Cashmere, the finest tints being known as the cornflower and the velvet blue. Rubies of large size are extremely rare, and when they are as much as three or four carats in weight, they are worth from five to ten times the price of diamonds of the same size. Sapphires are found in Montana at several points; the finest are mined at Yogo Gulch, in Fergus County; these are of fine rich blue. Other mines are at Rock Creek, Granite County, where there is a great variety of colors; also at Cottonwood Creek, and along the bars of the Missouri, not far from Helena. True rubies have been obtained lately in the Cowee Valley, Macon County, North Carolina, though not in large numbers.

Emeralds.— Emerald and beryl are in fact the same mineral, a silicate of alumina and glucina. Beryl varies from blue through light green to yellow, when it is called golden beryl, and forms a gem resembling topaz. If colored a deep rich green by a little oxide of chromium, it becomes the emerald, a stone which when flawless, ranks in value with the diamond. The chief source of fine emeralds has long been the mines at Muzo, near Bogota, in Colombia, where they occur in a limestone rock. The mine has been worked by Europeans for three centuries, and previously by the native peoples of South and Central America. The emeralds known to the ancients came principally from Upper Egypt, near the Red Sea. These mines have been long abandoned and unworked, but are now being somewhat reopened. In the United States some very fine and large crystals of emerald have been found in Alexander County, N. C., though they were hardly clear enough to cut into gems. Very fine pale-green beryls (aquamarines) have been obtained in Maine, North Carolina, and Colorado, and golden beryls in Maine, Connecticut, and Pennsylvania. All the beryls crystallize in the hexagonal system, as six-sided prisms.

Chrysoberyl, a very hard gem, is a compound of alumina and glucina. It is a rare mineral, of various shades of yellow, brown, and light green. One variety contains minute impurities distributed between the layers of the crystal, and these layers so arranged by what is called "twinning," that when the stone is cut across the layers, the light is reflected or condensed in a transverse bright line; such a gem is called chrysoberyl cat's-eye.

Topaz is a rather complicated silicate of alumina, occurring in rhombic prisms and possessing a hardness of 8. It is generally yellow, also pale blue, pale green, pale brown, and white (colorless). The favorite tint is a peculiar yellow known as sherry-color. The finest come from Brazil and from the Ural Mountains; but some very handsome ones have been found in Colorado and Utah.

Tourmaline, another complex silicate of alumina, occurring in prisms of six, nine, or twelve sides, is usually black, but also of transparent red, green, and other colors, often singularly mingled in the same crystal. These are found in Brazil and Siberia, and also of great elegance at Paris and Auburn, Maine, Haddam Neck, Conn., and especially in San Diego County, California.

Garnet is the name of a group of minerals closely related in form and properties, but presenting a number of varieties. They are all very complex alumino-silicates, in which various metallic oxides enter as ingredients. The principal gem varieties are: almandine, or precious garnet, containing considerable oxide of iron; its color is a deep rather purplish or brownish red; pyrope, or Bohemian garnet, containing much magnesia, is a fine dark crimson, almost ruby color. These two are the red garnets of jewelry; when cut *en cabochon*, that is, not faceted but rounded, they are called carbuncles. Manganese garnet, or spessartite, is sometimes of a very beautiful orange-brown color; elegant gems of this kind have been found at Amelia Court House, Virginia. Uvarovite, or chrome garnet, is a rare variety of brilliant green color, resembling emerald, but the crystals are very small. Another green garnet of somewhat different composition, and with very brilliant lustre, from the Ural mountains, is called demantoid, or Uralian emerald. Much fine garnet is found in the United States. North Carolina yields a beautiful variety that has been called rhodolite,— a brilliant light red garnet, between almandite and pyrope in composition; these are largely mined in the Cowee valley, in Macon County. New Mexico and Arizona yield fine pyropes, often miscalled Arizona rubies, and equaling those of any other known locality. They are found where centipedes have carried them out in making the galleries of their hills.

Among the finest gem collections in the United States are the Tiffany-Morgan collection and the Bement-Morgan collections at the American Museum of Natural History, New York; the Isaac Lea collection, at the United States National Museum, Washington, D. C.; the Tiffany collection, Field Columbian Museum, Chicago, Ill.; the Tiffany collection, Golden Gate Museum, San Francisco, Cal.; and the Kunz collection, at the State Museum, Albany, N. Y.

Gem Expert, Tiffany & Co., New York.

Gems, Engraving of, the glyptic art, or lithoglyptics; the art of representing designs on precious stones, either in raised work (cameos) or by figures cut into or below the surface (intaglios). The latter method was practised at a very early period, and probably had its origin with the Babylonians 4000 B.C., who worshipped the heavenly bodies, and were accustomed to wear figured talismans, which served as symbols of their influences. The Egyptians cut the hardest kind of stones for like purposes as early as 3000 B.C. The custom of wearing cut stones as seal-rings appears to have been general among the Greeks in the time of Solon. One of the earliest artists in this branch of whom mention is made is Mnesarchus, the father of the philosopher Pythagoras, consequently a contemporary of that Theodorus of Samos who engraved the ring of Polycrates, of which such wonderful stories are told by the ancients. These early works were probably intaglios; the artist made use of the lathe, the diamond-point, and by some it is thought, diamond-powder; but it is a question if the diamond was known before the 6th century A.D. Gem engraving flourished in Mycenæ, Smyrna, and ancient Greece, and from the time of Alexander the Great; but we can only judge of the works of Pyrgoteles, Apollonides, and Cronius from tradition, as there are no works of these masters extant. Pyrgoteles was distinguished for works in relief, and from his time the art may have risen gradually to that later degree of perfection of which we possess such rich specimens. The artists, some of whose names we learn from their works themselves, often took the masterpieces of sculpture for their subjects and models. Under the Roman emperors, in particular, this was very common. The chief early Greek engraver whose name is known from extant works of his is Dexamenos (late in the 5th century). The names of Dioscorides, Apollonides, Aulos, Hyllos, Cneius, Solon, remind us of the most perfect works in this branch of art, and many of the signed gems are forgeries or old gems with old names forged on them. But some of the greatest ancient works — the sardonyx of the Sainte Chapelle (Paris); the apotheosis of Augustus, at Vienna; the onyx at The Hague, representing the apotheosis of the Emperor Claudius; Achilles lamenting Patroclus; the head of Julius Cæsar — these, like the Brunswick vase and the Trivulcian and Neapolitan cups, bear no distinguished names. Pompey consecrated the dactyliotheca or collection of rings of Mithridates, as a votive offering in the Capitol, and Julius Cæsar, six tablets with six gems in the temple of Venus. At a later period the collections of Herodes Atticus, of Vespasian, etc., were celebrated; yet this general taste was not able to preserve the art from decline. Notwithstanding this decline, however, gems continued to be highly prized, even in the times of mediæval barbarism, and served to ornament the shrines of saints, and for royal badges, and ceremonial dresses, and thus passed safely through the ages of destruction and ignorance in which the finest statues were only valued as materials for mortar or for building, till ages arrived which could again appreciate their value. If we may judge from the remains which have come down to us, engraved gems seem to have been more common in the Byzantine empire than in the West.

The earliest gem-engraver of modern times is Vittore Pisanello, who lived in Florence about the year 1406. The first among the Germans was Daniel Engelhard, of Nuremberg, who died in 1512. The discovery of some fine specimens in Italy, particularly in Florence, and the display of gems by the Emperor Palæologus, at the Council of Florence in 1438, were perhaps the original cause of the taste of the Medici for engraved stones. The popes and that family were the first patrons of this art in modern times. A Florentine artist, generally called on account of his great skill, Giovanni delle Carniole ("of the Carnelians"), distinguished himself in this early modern period. There are few gems which can be ascribed to him with any confidence, except the famous carnelian in the Florentine Museum, with the portrait of Savonarola, bearing the inscription *Hieronymus Ferrariensis ordinis prædicatorum, propheta, vir et martyr.* This stone, which must have been engraved later than 1498, is given to Agincourt's work. Contemporaries and rivals of Giovanni were Nanni di Prospero delle Carniole, in Florence, whom Francesco Salviati directed in his works, and Domenico Compagnie (*dei camei*), a Milanese, whose portrait of Ludovico Sforza, called Moro, cut in a ruby, is still preserved in the Florentine Museum. After Bernardi (delle Carniole), Valerio Vicentino (under Leo X.) rendered himself famous as a gem-engraver. This art found patrons in all the Italian princes; the number of artists constantly increased, and the sphere of their work was extended. The names of these artists, however, are not generally known, because they are rarely put on the stones. Many gems, too, are still concealed in the cabinets of the wealthy or the treasuries of princes. Till these are accurately described, as those of the Ambrosian collection, it will be difficult to obtain a complete general view.

Subjects of antiquity were preferred by the artists of the 15th and 18th centuries, who treated them with such ability that it often requires the skill of the most accomplished connoisseur to distinguish them from genuine antiques. The dispute concerning the famous seal-ring of Michelangelo is well known. It is not improbable that this carnelian is the work of Pietro Maria da Pescia; as the figure of the fisherman in the exergue may indicate the artist who, with Michelino, belonged to the age of Leo X. In order to give the gems more completely the appearance of antiques, some artists engraved their names in Greek, but with so little knowledge of the language that they sometimes betrayed themselves by this artifice. To this time we must ascribe the gems with the name Pyrgoteles, which Fiorillo endeavors to prove were

the work of an Italian of Greek descent (Lascaris).

The art of engraving was also applied to glass and gold. The crystal box of Valerio Belli, the most skillful and industrious artist in this branch during the 16th century, deserves particular mention. It was intended by Clement VII. as a present to Francis I., when Catharine di Medici went to Marseilles in 1533. At present it is in Florence. The Milanese particularly distinguished themselves in gem-sculpture, as the wealth of the principal citizens of Milan enabled them to patronize this art. Jacopo da Trezza, the same artist who in 1564 executed for Philip II. the famous tabernacle of the Escurial, made the first attempts at engraving on the diamond in Milan. The greatest cameo work of modern times is the stone from the Florentine Museum, seven inches in breadth, on which Cosmo, Grand Duke of Tuscany, with his wife, Eleonore, and his seven children are represented. A Milanese, John Anthony de Rossi, who was a contemporary of the Saracchi family (about 1570), is the artist. The Saracchi were five brothers, and the crystal helmet of Albert of Bavaria is a proof of their skill.

Gem-engraving was popular in Germany in the 14th and 15th centuries, and in England, Natter, Pichler, and Marchant are considered the restorers of the art in later years in that country. The most eminent artist of more modern times is perhaps, Berini, a native of Rome, who, with Cervera and Giromelli at Rome, and Putinati, at Milan, produced very fine works. In our own times the demand for cameos and intaglios in the United States was greatest from 1870 to 1880. During that time more than 100 workmen found employment here,— many of them as portrait artists. Among these was Lebrethon, who had as a pupil our great sculptor Augustus Saint Gaudens; another, Zöllner, who engraved some fine and important cameos, took up brass working. Perhaps the greatest artist and the most active, L. Bonet, to-day has scarcely one sixth of his time occupied, whereas in the "Cameo age" he had the aid of nine assistants. In 1903 there appeared a slight revival of the wearing of antique and old-fashioned cameos of rather a pronounced form, and it is quite possible that the glyptic art is again on the way to favor.

A few of the gem collections are the famous Rev. C. W. King collection of antique gems, of the types used in his works; the Cesnola and other collections, at the Metropolitan Museum of Art; also a fine collection at the Boston Museum of Fine Arts; and the Maxwell Somerville collection, the types of his works, at the University of Pennsylvania, in Philadelphia, while the Walters collection, at Baltimore, Md., contains many of the finest gems in America.

Gems, Mythology of. The ancients believed that each month of the year was under the influence of a precious stone, and in modern tin s this superstition has found many devotees. It is quite the prevailing custom in many fashionable European capitals to wear birth-month stones, in preference to other jewels. The following list has been current for many years:

January	Garnet	Constancy
February	Amethyst	Sincerity
March	Bloodstone	Courage
April	Diamond	Innocence
May	Emerald	Success in love
June	Agate	Health and long life
July	Cornelian	Content
August	Sardonyx	Conjugal felicity
September	Chrysolite	Antidote to madness
October	Opal	Hope
November	Topaz	Fidelity
December	Turquoise	Prosperity

The seven gems which are supposed to be undc the influence of the seven chief planets are these:

Saturn	Onyx
Jupiter	Cornelian
Mars	Diamond
Sun	Sapphire
Venus	Emerald
Mercury	Loadstone or lodestone
Moon	Crystal

The legend of the diamond tells how Diamond was the name of a beautiful youth of the island of Crete, who was one of the attendants of the infant Jupiter in his cradle. Diamond, not to be subject to "the ills that flesh is heir to," was transformed into the hardest and most brilliant substance in nature. The diamond among the ancients had the virtue of bestowing victory and fortitude. It calmed anger and strengthened wedded love; hence it was called the stone of reconciliation. The diamond, too, among the Greeks was a symbol of severe and inexorable justice and of the impassibility of fate. Hence the judges of Hades were described as having hearts of adamant.

Gemsbok, gĕmz'bŏk, a large South African antelope (*Oryx gazella*), gray in general hue, but along the back, on the hindquarters, and along the flanks the color is deep black. It has a short erect mane, a long sweeping black tail, and long sharp-pointed heavy horns, nearly straight from base to tip, and obscurely ringed throughout the lower half. It is asserted that the gemsbok never drinks water, the moisture which it needs being obtained from the succulent bulbous plants on which it feeds. It is one of a group of large antelopes, including the oryx, beisa, addax, etc., which are sometimes called the gemsboks, and the numbers of all which are rapidly diminishing toward extinction. See Antelope.

Gemünder, August, ow'goost gĕ'mün-dĕr, German-American violin-maker: b. Ingelfingen, Würtemberg, 1814; d. New York 1895. He studied the art of violin-making with Vuillaume at Paris; from 1846 to 1860 was at Springfield, Mass., where he won wide recognition for his violins; and in 1861 established his business in New York. His most important work was a copy of an Amati owned by Pablo Sarasate, the well-known Spanish violinist, who declared it equal to the original instrument.

Gemünder, George, German-American violin-maker: b. Germany 1816; d. New York

1899. He was a pupil of Baptiste Vuillaume of Paris, came to America in 1847, won the first prize with his violins at the Crystal Palace exhibition, London (1851), and in 1873 sent to the Vienna exhibition a copy of a Guarnerius declared by the jury of experts to be an original. It is said that his were the finest violins yet made in America. He published 'George Gemünder's Progress in Violin-Making' (1881). He was a brother of August Gemünder (q.v.).

Gendarmes, zhŏṅ-därm (Fr. «men-at-arms») were originally mounted lancers, armed at all points, and attended by five inferior soldiers, who were furnished by the holders of fiefs; these were replaced by Charles VII.'s *compagnies d'ordonnance,* which were dissolved in 1787, one company of gendarmerie being retained as the bodyguard of Louis XVI. Since the French Revolution, except for a short interval at the Restoration, the gendarmes have constituted a military police, which superseded the old *maréchaussée,* and comprises both cavalry and infantry; divided into legions and companies, and these latter into brigades, the organization of the force corresponds to the territorial divisions of the army. The men receive much higher pay than the rest of the army, of which, however, the corps is a part, its members being drafted from the line for this service. Germany also since 1808 has had its *gendarmen.* See POLICE.

Gender, in grammar, a difference in words to express distinction of sex. Strictly speaking there are but two genders, the *masculine* and *feminine;* words which did not belong to those classes were said to be *neutrius generis,* of neither gender; and from this phrase grammarians have, somewhat incorrectly, come to speak of this third class as being of «the neuter gender,» and thus recognize three genders. That the distinction of sex is the origin of grammatical gender cannot be reasonably disputed, and as a consequence the principle must have been originally restricted to living beings, and practically to those in which the distinction of sex was readily perceived. In the lesser animals it would have been more difficult to ascertain the sex, and generally unnecessary to denote it. But correctness and utility are not the only ruling principles of language; they are often sacrificed to the love of imagery and personification. In the infancy of language, when everything that was seen to produce an effect was conceived as actuated by a conscious will, every prominent object was endowed with one or other sex, the choice depending on the association of ideas. Strength, freedom, magnitude and violence are the marked attributes of the male; weakness, subjection, timidity, and gentleness of the female. In Hebrew there is no neuter; in Sanskrit, Greek, and Latin, the majority of the names applied to inanimate objects are either masculine or feminine; and in the languages derived from the Latin — Italian, French, Spanish, and Portuguese — a neuter gender is not recognized. In German, as in the classical tongues, the names of inanimate objects are sometimes masculine and feminine as well as neuter. English, getting rid of the spurious distinction that encumbered the Anglo-Saxon, attributes sex only to living beings. In the highly inflected languages there are certain terminations distinctive of the different genders, the most characteristic in the Greek being *os,* masc.; *ē,* fem.; and *on,* neuter; and the Latin *us, a, um.* In English the distinction of gender is often marked by the termination, the most common being the affix *ess* derived from the French; or by a different word. In most other languages the adjectives, articles, and participles are inflected for gender; in English the gender of a noun only affects the pronoun substituted for it. See GRAMMAR; LANGUAGE.

Gender, a Javanese musical instrument. It consists of a row of parallel metallic plates supported horizontally by two strings passed through the respective nodal lines of the plates. Underneath each plate is an upright bamboo, containing a column of air of such a height as to reciprocate the sound of the plate above.

Gendron, Auguste, ō-güst zhŏṅ-drôṅ, French painter: b. Paris 1818; d. there 12 July 1881. He was long a pupil of Delaroche, and several times visited Italy, where he painted his first important works. In addition to several canvases, including 'The Island of Cythera'; 'Tiberius at Capri'; 'Sunday in Florence — 15th Century'; he executed frescoes in the Louvre and the church of St. Gervais.

Genealog'ical Society, The New York, was incorporated in 1869, to procure and perpetuate whatever may relate to genealogy and biography. The 'New York Genealogical and Biographical Record,' now in its 28th volume, is published under its supervision. The society has published: 'Marriage from 1639 to 1801 in the Reformed Dutch Church, New York,' and other volumes. The society's building is at 23 West 44th Street.

Geneal'ogy (from the Greek *genos,* race, and *logos,* discourse), the systematical account of the origin, descent, and relations of families is an auxiliary of historical science. Genealogical knowledge becomes important in a personal or legal view, when family claims are to be established. Genealogy is founded on the idea of a lineage or family. Persons descended from a common father constitute a family. Under the idea of degree is denoted the nearness or remoteness of relationship in which one person stands with respect to another. A series of several persons, descended from a common progenitor, is called a line. A line is either direct or collateral. The direct line is divided into the ascending and descending. The ascendants are called, in general, *majores* (ancestors), and the descendants *posteri* (or posterity). The collateral lines comprehend the several lines which unite in a common progenitor. They are either equal or unequal, according as the number of the degrees in the lines is the same or different. The collateral relations on the father's side are termed *agnati,* on the mother's *cognati.* Children stand to each other in the relation either of the full blood or the half blood, according as they are descended from the same parents, or have only one parent in common.

For illustrating descent and relationship genealogical tables are constructed, the order of which depends on the end in view. In tables the object of which is to show all the individuals embraced in a family, it is usual to begin with the oldest progenitor, and to put all the persons of the male or female sex in descending, and then in collateral lines. Other tables exhibit the ancestors of a particular person in ascending

lines, both on the father's and mother's side. In this way 4, 8, 16, etc., ancestors, are exhibited. The tables showing the succession of rulers contain merely the descent of the persons who have reigned in succession, or who have claims to the government. In connection with them stand the tables of disputed succession, which represent several lines of a family, or several collateral families, in order to deduce their rights of succession from their degree of relationship. Synchronical tables consist of the genealogies of several families placed together, in order to compare, with facility, relationships, marriages, divisions of inheritance, etc. Historical genealogical tables differ from mere genealogical tables, as they attach to the descent the biographies also of the members. The common form of genealogical tables places the common stock at the head, and shows the degree of each descendant by lines.

The earliest genealogical tables are perpetuated in the Biblical family records of succeeding generations, in graven stone memorials of ancient Egypt, Assyria, Persia, India, and other oriental countries. Genealogical knowledge was most important in the Middle Ages, when the nobility was distinct from the other classes. Ancestors were unblushingly and impudently fabricated, the absence of criticism and the desire to flatter important people causing the introduction of the most absurd fables into genealogy, especially after the 14th century. Few families, no matter however distinguished and noble, can trace their ancestry beyond or even as far as the middle of the 11th century. The advance of civilization and particularly the institution of corporations and guilds in the towns of the principal European nations, afforded a wider scope for genealogy, and in the 12th and 13th centuries, family names began to be more common. The oldest trace of family names according to Gatterer is in 1062 when a Henricus de Sinna is mentioned in Schannat's "Buchonia Veteri." After history in general had attained a more systematic character, the Germans in particular treated genealogy on a more scientific basis. Ruxner's "Turnierbuch" (1527), and Reusner and Hennings' genealogical tables which appeared about the end of the 16th century, are among the earliest published works, but are not conceived in an historical spirit. Duchesne, Saint Marthe, Hozier, Chifflet, Lancelot le Blond, etc., in France, and Dugdale in England, initiated a clearer and more accurate treatment of the subject. The first genealogists in Germany to base the science on documentary evidence were Rittershusius of Altdorf (d. 1670) and Spencer of Wittenberg (d. 1730). The lines laid down by them were followed and carried to higher perfection by König, Von Imhof, and especially by Hübner in his "Genealogische Tabellen" (4 vols. 1725–33; new ed. 1737–66), to which Lentz added "Erläuterungen" (Elucidations, 1756), and Sophia, Queen of Denmark, "Supplement-Tafeln" (1822–24). Gatterer founded the scientific treatment of the subject in his "Abriss der Genealogie" (1788), and was followed by Pütter in his "Tabulæ Genealgicæ" (1798), by Koch in his "Tables Généalogiques" (1808), Voigtel (1810), Hopf (1861), Von Behr (1870), Cohn (1871), and Oertel (1871), all in Germany.

The principal genealogical MSS. sources in Great Britain are the public records, heraldic registers, and the parish registers of births, marriages, and deaths. The chief printed collections of genealogical information are the well-known Burke, Debrett, and other like publications of "Peerages, Baronages, Baronetages, and County Histories."

In the United States, genealogy was generally neglected until the latter part of the 19th century, when the organization of patriotic, State and colonial societies, like the Society of the Cincinnati, the Holland Society of New York, the Southern Society, etc., aroused an interest in genealogy. Genealogical societies have been organized in several States and the subject has received more or less attention. New York society folks in 1901–2 began to take up genealogy as a special fad or hobby and numbers of persons adopted the study of family trees as a regular employment. The principal publications in the United States on genealogy are 'The New England Historical and Genealogical Register;' 'The New York Genealogical and Biographical Record;' 'The Heraldic Journal;' the various biographical dictionaries and cyclopedias; the printed transactions and archives of State and city historical societies; county, State, city, and town histories.

Genee, zhē-nā, **Rudolf,** German author: b. Berlin, Prussia, 12 Dec. 1824. He abandoned wood engraving for journalism, and then became an instructor in literature at Berlin. As a reader and interpreter of Shakespeare he attained distinction; but his plays — 'The Prodigy' (1854); 'A New Timon'; 'In Front of the Cannon'; 'The Hermitess"; and adaptations from Sheridan — gave him wider fame. His works in criticism, treating of German poetry, the drama, and kindred themes, are highly esteemed. 'Marienburg' is a successful historical novel by him.

Genelli, Bonaventura, bō′′nä-vān-too'rä gā-nĕl'lē, German painter: b. Berlin 28 Sept. 1798; d. 13 Nov. 1868. He was the son of Janus Genelli (1771–1812), an engraver, with whom he early studied. His chief artistic training was obtained as a pupil of Johann Erdmann Hummel at Berlin and at Rome, where he resided in 1822–32, and executed numerous pencil and india-ink drawings which carried his name over much of the continent. From 1836 he was in Munich, often in poverty; for he received no public commissions and his work had as yet met its due recognition among but a few. In 1859 he was called by Grand-duke Charles Alexander to Weimar, where ample leisure was afforded him for his larger works in oil. He was a classicist like Carstens, whose methods he followed, and with him the chief thing was the rendering of line. Among his many works are the series of drawings for Dante's 'Divine Comedy,' and for Homer; other drawings in ink or water-colors, such as 'Hercules Playing the Lyre'; The 'Vision of Ezekiel,' and 'Æsop Telling His Fables,' and the pictures in oil: 'Abraham and the Angels'; 'The Battle of Lycurgus with Bacchus'; 'Bacchus among the Muses.' There is a biography of Genelli by Jordan (1869).

General, (1) A military rank and title. In the United States army, this rank, as distinguished from and superior to the major-general,

was created for Washington by Congress, 3 March 1799. He died shortly after, the office remained vacant, and in 1802 it was abolished. It was revived in 1866 for Grant, and on his accession to the Presidency in 1869, was conferred on William T. Sherman. On his retirement, 1 Nov. 1883, the rank was allowed to lapse. In June 1888 it was revived for Philip H. Sheridan; but on his death in August it again became extinct. The highest army officer has now the title of chief of staff. See GENERAL STAFF, UNITED STATES ARMY.

(2) The name given to the general superior of religious orders and congregations of men in the Roman Catholic Church. The general is usually elected in general chapter, and holds office for three years. In the Society of Jesus the general is elected for life. The generals of regular orders have been granted by popes special privileges, as power of absolution in reserved cases in relation to their subjects. Several modern congregations of women have general superiors, but their canonical position is quite different from that of the generals of the orders of men.

General Assembly. See ASSEMBLY, GENERAL; PRESBYTERIANS.

General Confession, in the Roman Catholic Church, is a sacramental confession of all sins committed by the penitent since baptism, or since of an age to know what sin is, so far as he can remember. Such general confession is made by persons who have made no previous confession, who have wilfully concealed a mortal sin; or been wanting in true and supernatural sorrow for the sins confessed in a previous confession; or are desirous of reviewing their past life for the purpose of interior advancement in the spiritual life.

General Court, the official name of the legislature of Massachusetts. The old English name of the meeting of a body of managers or members of any corporation is "court"; as court of aldermen, court of directors, etc. So the meeting of corporators of the old Massachusetts Company was called a court; then the primary assembly of freemen under its charter was called the General Court; and the name was retained after it became a representative body. There was the further reason that it really was the supreme judicial as well as legislative body. See MASSACHUSETTS.

General Education Board founded in New York City, February, 1902, chartered by Congress 12 Jan. 1903, has for its objects: (1) The promotion of education within the United States of America, without distinction of race, sex or creed; (2) the development of the public school system, especially in rural districts; (3) the development of the principle of self-help by promoting increased local taxation, local contributions or other means for educational purposes; (4) the increased establishment of training schools for teachers, especially those designed to educate instructors of industrial and manual training; (5) co-operation with the organizations interested in educational work, so as to simplify and make effective the general work of education, avoiding unnecessary duplication; (6) the collection of full information and statistics in respect to educational matters in the districts covered by the operation of the board, which shall be kept at a general office; (7) to furnish the public with information, suggestions and counsel, and for this purpose to act somewhat as a clearing-house for educational statistics and data to be collated by the board; (8) to educate public opinion in all matters pertaining to the general cause of education by publication of reports through the daily press and by other means.

The organization received the cordial support and gifts of several philanthropists, including John D. Rockefeller, Sr., and among the members of the board are John D. Rockefeller, Jr., Daniel Coit Gilman, Morris K. Jesup, William R. Harper, Frederick T. Gates, Walter H. Page, Albert Shaw, Hugh H. Hanna, E. Benjamin Andrews, Starr J. Murphy, secretary and executive officer for the states of the north and west; Wallace Buttrick, secretary and executive officer for the states south of the Potomac and Ohio rivers, and Arkansas, Louisiana and Texas; George Foster Peabody, treasurer; Robert C. Ogden, president.

When the charter with its broad provisions was signed by President Roosevelt, John D. Rockefeller made a special gift of $1,000,000 for exclusive distribution in educational work among the southern states, where the operations of the board were mainly confined at first. The intelligence, fidelity and efficiency with which this trust was discharged led Mr. Rockefeller, 30 June 1905, to announce a further contribution to the General Education Board of a sum of $10,000,000 to be paid October 1 of that year, in cash, or at his option in income-producing securities, at their market value, the principal to be held in perpetuity as a foundation for education, the income, above expenses and administration, to be distributed to or used for the benefit of such institutions of learning, at such times, in such amounts, for such purposes and under such conditions, or employed in such other ways as the board may deem best adapted to promote a comprehensive system of higher education in the United States. According to the success and usefulness of the fund, considerable additions in future years were promised by Mr. Rockefeller.

While the endowment is designed especially for colleges as distinguished from universities, there is no prohibition against making contributions to universities. The funds may be employed for approved non-sectarian as well as denominational schools, but in the case of the latter cannot be applied for specific theological instruction. In distributing the funds the board aims especially at favoring those institutions which are well located and which have a local constituency sufficiently strong and able to insure permanence and power. No attempt will be made to resuscitate moribund schools or to assist institutions which are so located that they cannot promise to be permanently useful.

Within these limits there are no restrictions as to the use of the income. It may be utilized for endowment, for buildings, for current expenses, for debts, for apparatus or for any other purpose which may be found most serviceable, thus providing for a great work in a practical way.

General Issue, in English law, is that plea which denies at once the whole declaration or

indictment, without offering any special matter by which to evade it. It is called the general issue, because, by importing an absolute and general denial of what is alleged in the declaration, it amounts at once to an issue, or fact affirmed on one side, and denied on the other. This is the ordinary plea upon which most causes are tried, and is now almost invariably used in all criminal cases, when the prisoner at the bar pleads "not guilty"; to money counts the plea is "never indebted"; or to actions on simple contract *nunquam assumpsit* ("never undertaken"). This plea puts everything in issue, that is, denies everything, and requires the party to prove all that he has stated. It is a frequent question, What can be given in evidence by the defendant upon this plea? and the difficulty is, to know when the matter of defense may be urged upon the general issue, or must be specially pleaded upon the record. See PLEA; PLEADING.

General Par'esis (known also as general paralysis, softening of the brain, paralytic dementia, paralysis of the insane, etc.), a disease of the nervous system that usually begins in early adult life, progresses steadily with increasing mental enfeeblement, and leads to ultimate motor paralysis, decay of all of the mental faculties, and death within a period averaging from three to five years. From the type indicated in this brief general definition there are numberless variations. It is a disease which, when well advanced, is recognized with great ease, but in its early stages it may be extremely difficult to know. From the standpoint of the patient's family and friends it is important to be able to recognize the disease; for it is in this initial period that the patient often ruins his business, his friends, his family, and brings shame and discomfort to all those connected with him. Much of this might be averted if the layman were better informed of this early period of one of the worst scourges of modern times. The disease has probably existed for many centuries, but it is only within comparatively recent times that its true character has been recognized, and in its present extreme forms it seems to be a product of the modern complex social system. It has been aptly termed a disease of civilization and *syphilization,* an alliteration that contains much truth. General paresis may develop in almost any one, but there are certain necessary antecedents and numerous contributory factors. It is believed by most students of mental diseases that syphilis is one of the most important antecedents. Accurate statistics on this point are extremely difficult to obtain, but most alienists believe that from 60 to 90 per cent of patients who have developed paresis have had syphilis. This as a purely statistical argument is of course no proof that syphilis is the cause of paresis; for probably 99 per cent of paretics have had measles, or whooping-cough; yet the changes that are found in the blood vessels of the brain in paretics are very closely allied to changes in the blood vessels known to result from the poison of syphilis. The theory of the syphilis etiology is, therefore, probably true for most cases, but not necessarily so. Another extremely important item is a characteristic mental type. In an extremely large number of paretics the mental character has been that of great emotional activity. People who use their brains very hard, and who can key them up to a high pitch, seem to succumb to this disease more than those of evener temperamental tone. It is this type, as seen in actors, in salesmen, in active business men, who become infected with syphilis, that is peculiarly liable to the disease. It is also this temperamental type that indulges in excesses of various kinds — excesses of work, of play, of excitement, of worry, of alcohol, of venery — and thus are undermined the foundations of healthy nerve-tissue, leading to its premature decay.

General paresis is commoner in men than in women, the proportion among different peoples and races, and times, varying from 25–1 to 3–1. Although it is a disease usually beginning in the thirties or forties, juvenile forms are known, and sometimes the old man is a victim. It seems to be more prevalent in crowded communities, for there the stress of excitement and depression, of gaiety and sadness, of extravagance and destitution, is more pronounced, for both extremes of the mental pendulum must be considered in the estimation of the causes of paresis. The brilliant financier, or the actress who succumbs to this disease may be more in the public eye, and moralists may adorn a tale concerning their supposed profligacy, but the poor harassed workman, diseased through lack of knowledge, and drink-sodden to escape the reproofs of his conscience, may also be the victim.

The initial symptoms are usually very insidious, although occasionally the disease appears in full-blown vigor. The previously healthy, neat, and careful workman begins to forget things. There is a period of disturbed mentality. Noises affect him unpleasantly. Undue irritability is evidenced by unwonted explosions of anger. This state may be weeks or months in its evolution, and may be confounded with a condition of overwork or overworry. In fact, such a condition is present in many tired people who never develop paresis. Added to this there are vague apprehensions in the patient's own mind of his gradually declining power; headaches, neuralgias, and vague pains may also be present; and poor sleep may be another symptom of the early stage. All of these symptoms are common to many people who have overworked, and should not occasion alarm. But when, little by little, one shows increasing carelessness in his personal habits, such as neglecting to button his trousers, or permitting his food to spill on his clothing, when he shows signs of mental exaltation and dreams of wonderful things, then the true disease begins to show itself. From this point on there are countless variations, but in general the typical paretic behavior that leads the person into economic danger, if not disaster, is characterized by an expansive and exaggerated conduct. Buoyancy and elation, with great projects and sanguine hopes, mark the initial stages of the paretic's mental decay. He becomes restlessly busy, is continually entering into new schemes, is incessantly talking about his affairs with effusive geniality, not only to his friends, but to utter strangers, and he even communicates to others his closest domestic concerns. There is a gradual breaking down of the finest sensibilities and, closely following this, slight evidences of the

loss of the most delicate motor adjustments become manifest. It is in this stage that the symptoms become unmistakable. The partial impairment of the motor functions shows itself in an increased lack of control of the finer motions of the tongue, the lips, and the hands. There is a fine tremor in the tongue when it is protruded; on showing the teeth, the angles of the mouth betray a fine tremor; and the handwriting is seen to be less firm and even, approaching that of the formative period of the man's youth. The mild grade of inflammation in the brain causes certain changes in the reflexes of the body. Thus, the pupils of the eyes are not apt to act as rapidly as in health; they may be unequal in size; they are sometimes very small and do not open wide in the dark as is usual. With these symptoms the diagnosis becomes moderately certain, and from this time on the mental degeneration becomes marked. The carelessness becomes slovenliness; the memory goes rapidly; the loss of the finer sensibilities deepens to obscenity, to faithlessness, to utter loss of the moral faculties; the buoyancy becomes foolishness, and big projects are often launched, resulting in financial ruin. Grandiose ideas usually enlarge, and the afflicted one dreams of millions of money, of being a king, or president, or Christ, or a god. His personal strength is like that of Samson, his beauty comparable to Apollo's; his voice, his oratory, his writing, his poetry, his acting are superb — in short, his whole personality is puffed up with an amazing exaltation of the ego. Exulting self-confidence dominates all his designs, and a restless, busy, subdued delirium actuates his every thought and movement. From this stage, usually termed the grandiose stage, and which may persist for from six months to a year or more, the mental deterioration commences to show itself in a gradually progressive dementia. Mental dilapidation becomes mental decay. The motor restlessness goes on to loss of power and a gradual paralysis of the motor functions begins, passing through the stages of progressively increasing inco-ordination to complete powerlessness. Tottering, shambling, stumbling incompetence finally advances to absolute motor impotence. This affects all of the muscles of the body, but is appreciated in the speech more readily and earlier than in other motor acts. The loss of ability to repeat the r's and l's, as in «truly rural,» «artillery,» etc., is an early sign of this speech-defect. Finally the only answer that can be obtained from the patient is that he is «all right.» The lack of motor power further manifests itself in the increasingly diminished control of handwriting. The paretic is unable to keep to a line. His writing goes up and down, letters and words are omitted, the up strokes are very wavy, and the letters become unequal in size.

Thus the course of the disease progresses until, in from two to three years, on the average, the paretic is a bedridden dement, who dies of exhaustion or an apoplectic or epileptiform convulsion. Occasionally remissions of the disease occur. These are particularly trying to most of the paretic's friends, for hopes of recovery receive a sudden stimulus only to be destroyed after a period of from six months to a year or so. Occasionally the remissions last a number of years, but at the present time it is believed that general paresis is a necessarily fatal disease. Alienists have a habit of calling the recovered cases pseudoparesis, a justifiable procedure in view of the many uncertainties attending the diagnosis of mental disorders.

The main features of a central type of the disease are here given, but there are countless variations. Acute maniacal states sometimes occur, and the patient dies in a galloping frenzy in from three to six months. Occasionally a paretic is melancholic or stuporous throughout. A small proportion, one half per cent of the cases, show this type. Occasionally — and many modern alienists believe this to be more common at present — a gradually progressive dementia without grandiose ideas marks the entire course of the disease. Most cases of paresis have apoplectiform or epileptiform attacks at some period of the disease. A few begin in this manner. There are countless numbers of mixed forms, the details of which may be consulted in text-books on insanity. Here also the subdivision of the disease into stages may be found.

Of the treatment little may be added. The most essential step in relation to this disease is its early recognition. To be able to know what is the matter before the patient has ruined his business, or his family and friends, is the most important feature for the layman to grasp. The paretic himself is doomed, but it is not necessary for those dependent on him to suffer irretrievable loss because of his disease. The proper course to pursue is to place the patient in a sanatorium or asylum at the earliest possible moment, the place selected depending largely on the means of his friends or relatives. SMITH ELY JELLIFFE, M. D.,
Editor 'Journal of Nervous and Mental Disease.'

General Service and Staff College, United States army, a training school for young officers of the United States army, located at Fort Leavenworth, Kan. Graduates from West Point are sent here for a further study of the profession of arms, and a more practical and theoretical training from the standpoint of the officer. Upon completing the course of study an officer returns to duty with his regiment. The course of study (1903) is one year, but, after the graduation of the class for 1904, will be extended to two years. At graduation the student class is divided into two classes, the «distinguished» class and the «proficient» class, the former becoming available for detail at the War College at Washington. The books to be used during the school year of 1903-4 are as follows: 'Horses,' 'Saddles and Bridles,' 'International Law,' 'Manual of Military Field Engineering,' 'Military Hygiene,' 'Military Law,' 'Military Topography and Sketching,' 'Organization and Tactics,' and 'Service of Security and Information.' See ARMY OF THE UNITED STATES; ARMY WAR COLLEGE.

General Sessions, Court of. See COURT.

General Staff of the Army, in the United States. History evinces that most competent and courageous commanders have at times charged failure of their operations to lack of preparation for which they were not responsible, or to ill-considered interference by those in high public office. Each successive war has developed accusations of shortcomings which though often indefinite, pointed in the main to defective organization and administration at the War Department. No two nations seem to favor identically the same methods of military administration, yet all have the same objects in view — correct organization, modern equipment, preparedness to strike the first blow with an assured and continuous supply of men, money, and war stores, during hostilities. During the early years of the United States the army was insignificant in proportions, but the business of the War Department gradually grew in volume until it was necessary to adopt some measures to save the secretary of war from being crushed by the burden of current routine work. In groping for some method which would relieve the secretary, the bureau system with numerous semi-independent chiefs was introduced. These bureaus were few in number at the beginning but gradually grew until at the commencement of war with Spain there were 10 chiefs of bureaus directly connected with the administration and supply of the army, each working along his own lines without of necessity having any knowledge of the character and extent of allied work going on in other bureaus. The army is absolutely dependent upon these administrative and supply bureaus and success depends upon the co-ordinated total of all their efforts. During a long course of years a system of laws and regulations had grown up for the governance of these bureaus. These bureaus have been controlled by many talented officers through whose honest and laborious efforts success has been made possible in the wars of the century just closed. It has gradually come to be the conviction of a large and increasing number of thoughtful and discerning officers and public men that success has been wrought in spite of the system and not altogether because of it. Chiefs of bureaus found themselves constantly hampered by reason of lack of information. Not by law but as a matter of expediency all looked to the adjutant general for information, but chiefs of bureaus claimed that the secretary of war alone was competent to give them orders or instructions.

Nations which depend upon volunteer armies are apt to ignore the lessons of war and to consider that all that goes wrong is chargeable to unusual conditions and not to lack of previous preparation. This lethargy would have supervened at the close of the brief war with Spain had not the insurrection in the Philippines and the occupation of Cuba commanded further attention to military matters. In all armies there are many important duties which by common usage have become designated as general staff duties. Much of the employment of general staff officers is in the nature of co-ordinating the action of others, but a large part is original work of the highest type. It was the lack of a corps of this kind which was always keenly felt in American army administration. It should be understood that general staff duties were not wholly neglected but their performance was spasmodic, uncertain and without fixed responsibility because executed by officers of other corps or of the line, detailed individually or as members of temporary boards.

After a patient and exhaustive study of the situation the secretary of war concluded that the more important duties of a general staff could be performed by a war college and its governing board. In furtherance of this idea a board of officers was convened to consider and recommend regulations for the establishment of an army war college. After mature study of the situation the board formulated a memorandum of an order for the execution of the project but unanimously recommended that a general staff be established by appropriate legislation which would free it from the uncertain tenure adhering to the war college which exists only by executive authority.

A continuing study of the manifold questions arising in the course of army administration brought prominently into view the never ending controversy as to the proper place of the "Commanding General of the Army" in the new scheme. The commanding general had long complained of loss of prerogatives believed to appertain to his office, while the generals commanding the geographical departments rebelled at being deprived of all initiative and being practically under the control of bureau chiefs, each naturally interested in enhancing the usefulness and dignity of his own bureau. The only solution which suggested itself as a practical and possible adjustment was the abolition of the office of "Commanding General of the Army" and the substitution of the office of "Chief of Staff," with the introduction of a new corps composed of trained officers to assist him. Out of these studies and efforts have come the law known as the General Staff Bill, which passed the Congress and was approved by the President 16 Feb. 1903.

Under this law the chief of staff, regardless of his relative rank, is the adviser and representative of the secretary of war, occupying a position between that official and the staff bureaus as well as the line of the army. Instead of 10 chiefs of bureaus and their numerous assistants having frequent interviews with the secretary concerning military affairs, the chief of staff has authority to adjust professional matters in the secretary's name. Conflicting elements of the larger administrative questions are thus brought together and harmonized without taking up the valuable time of the civilian secretary, who must of necessity acquaint himself concerning numerous technical details before undertaking to decide matters at issue. This is a decided improvement over the methods in vogue during the existence of the office of "Commanding General of the Army," for notwithstanding the title and high rank of the distinguished officers who have occupied that position, their influence and power over the army as a whole was so restricted as to be entirely incompatible with the title of their office.

It was not presumed in making so radical a change in the American military system that the general staff corps will be a panacea for all the misfortunes which may overtake a nation in war. History teaches that previous preparation and planning such as will be undertaken by the general staff will tend to render success more certain, abbreviate the period of actual hostili-

ties and thereby effect an enormous saving of life and treasure. Commercial interests of all modern communities have become so enormous and widespread that a long-continued war means national paralysis to the defeated nation. Through the agency of the general staff, military and political policies may be harmonized as becomes a republican form of government. With the war policy determined, the general staff will be responsible that each part of the army line and staff is promptly acquainted with its duty and that it does its full duty in the premises. The preparation of armies and their equipment rests with the chief of staff and the various staff corps and departments. The responsibility for manœuvring the armies and for success in battle rests with the various generals assigned to command them. In past wars it has been the custom to depend upon Congress at the last moment to enact legislation for armies and grant appropriations at a time when, by reason of popular excitement, members are least able to give to the grave questions involved the consideration necessary.

The duties of the general staff consist, in peace, to a great extent, of bureau work — including the collection of information, preparation of maps, drawing up schemes for the organization and concentration of troops, formulation of plans for the national defense and a study of the higher military science to keep pace with modern progress. Bureaus organized and prepared to handle any particular class of army business will continue to initiate action and control its affairs subject to the supervision of the chief of staff. It is in the many important matters where the work of several bureaus must be harmonized and brought into the same channel, that the general staff will find its greatest field of usefulness. The general staff will be acquainted with contemplated changes in the organization and stations of troops and by preparing timely schemes will ensure arrangements being made for transportation and supply in the most expeditious and economical manner. The arrangement of all these interlocking details is necessary to successful campaigns of any duration. Armies are constantly called upon to endure all kinds of hardships, to which they submit cheerfully so long as there is no suspicion that any one is at fault. It is expected that the American general staff will plan to minimize the chances of failure due generally to lack of previous knowledge and preparation. The statute contemplates that the general staff corps shall be composed of officers detailed for periods of four years, and it is necessary that a sufficient number be maintained on duty to furnish details with troops as well as for bureau work. This ensures a body of officers in touch and sympathy with the fighting portion of the army. The general staff corps has been so recently organized that it will require some time to develop methods of operation, but as the soldierly spirit, informed by experience derived from actual service with troops, will be the guiding impulse of this corps, the expectation that the country will be better prepared for campaigning at the outbreak of the next war than it has ever been in the past, is fully justified. See ARMY OF THE UNITED STATES.

W. H. CARTER,
Brigadier-General, Assistant Chief of Staff.

General Theological Seminary, a seminary of the Protestant Episcopal Church in the United States, established in 1817. Instruction was begun in New York city in 1819, but in 1820 the seminary was removed to New Haven. It was again re-established in New York in 1822. The gifts of Dean Hoffman to the school amounted to over $1,000,000, while in 1902 the total resources of the school were over $4,000,000. The theological course of the school extends over a period of three years, and there is a post-graduate course. The degrees of D.D. and B.D. are conferred. The control of the seminary is vested in a board of trustees composed of the bishops of the Church, 25 members elected by the general convention and certain other members elected by various dioceses. There are about 150 students in regular attendance.

Genera'tion, popularly used as a measure of time, and usually represents about 30 years, the period which man requires to attain maturity, and the age at which, as a general rule, fruitful marriages are contracted. This secondary sense of the term is thus indirectly derived from the primitive meaning, which has reference to the origin of living things. In the higher animals and plants the offspring is due to the congress of distinct individuals or elements. (See REPRODUCTION.) Alongside of this process, sometimes even concurrently with it, new forms may arise by fission, or by budding; by a process akin to the latter, as in the parthenogenesis of bees, etc.; or by a combination of the sexual and asexual processes, alternate generation.

Generation, Spontaneous. See SPONTANEOUS GENERATION.

Gen'erator, (1) An apparatus for generating carbonic acid gas for charging soda-fountains or bottles with aërated water. (2) In chemistry, a term used to denote the elements or compounds from which a more complex substance is obtained. Thus ethyl, alcohol, and acetic acid are the generators of acetic ether; and benzoic acid and glycocoll are the generators of hippuric acid. (3) In distilling, a retort in which volatile hydrocarbons are distilled from liquid or solid matters. (4) In electricity, a dynamo-electric machine (q.v.). (5) In steam, a vessel in which steam is generated from water, for use in a steam-engine, a heating apparatus, etc. The term was first applied to the Perkins steam boiler, in which water in small quantity was heated to a high temperature. It is now specifically applied to a class of instantaneous generators. The name is now rapidly coming into use for all apparatus for generating steam, being held to be more correct than the usual term. See STEAM.

Genesee (jĕn-ē-sē') **River,** a remarkable stream rising in Pennsylvania, and flowing nearly 200 miles north through western New York into Lake Ontario, seven miles north of Rochester. The Genesee is famous for its extraordinary falls. Three of these occur within a distance of 1½ miles; two are respectively 68 and 90 feet high, and the Portage Falls are 110 feet high. The river has also a sheer fall of 95 feet at Rochester, utilized for water-power; and another cascade, a few miles below, is almost as high.

Geneseo, N. Y., a village and county-seat of Livingston County, 30 miles from Rochester, on the Genesee River and the Erie R.R. The State Normal School and Wadsworth Public Library are situated here. It is an agricultural town and manufactures gloves, mittens, flour, and machines. Pop. (1900) 2,400.

Gen'esis (Greek), creation, birth, origin. The first book of the Pentateuch is named in the Hebrew canon *B'reshith* (in the beginning), from the expression with which it commences; from the 70 translators of Alexandria (those who produced the Greek version known as the Septuagint) it received the name it is now commonly known by. Genesis consists of two great but closely connected divisions: (1) The history of creation, the fall of man, the flood, the dispersion of the human race, chap. 1–xi. (2) The history of Abraham, Isaac, Jacob, and Joseph, including notices of the descendants of Abraham and Isaac in their collateral lines, chap. xii.–l. It would be entirely to mistake the character of the history of Genesis to view it as having other than a sacred purpose; yet even in a secular point of view there is no record that can be brought into competition with it. There is absolutely nothing in the whole range of ancient literature which could supply its place if this document were lost; while it is further to be observed, that if confidence cannot be placed in its authenticity, no reliable information exists on many subjects with which it is desirable man should be acquainted, and after which there is an intense longing in the human mind; as, for instance, the origin and early history of the race, a subject which, without the information supplied by Genesis, must be involved in impenetrable darkness.

Genêt, or **Genest, Edmond Charles Edouard,** ĕd-môṅ shärl ā-doo-är zhĕ-nā, French diplomat: b. Versailles, France, 8 Jan. 1765; d. Schodack, N. Y., 14 July, 1834. In 1777 he translated into French a Swedish history of King Eric XIV. of Sweden, in 1789–92, was French *chargé d'affaires* at St. Petersburg, and from 1793–4, when he was recalled at Washington's request because of attempts to compel the United States to a war with England, was French minister to the United States.

Genet, jĕ-nĕt', a civet (q.v.) of the genus *Genetta;* also a trade-name for the fur of this animal, or of some other fur like it. The best known is the common genet (*G. vulgaris*), of the Mediterranean region, called "berbe" in the south of France. It is a very beautiful and graceful animal, gray, with many dark patches, and a full furry tail, banded with black and white. The size is about that of a house-cat. Their fur is made up into tippets, muffs, etc., but is of no great value, and often domestic cat-skins are substituted under the same name.

Genet'ic Psychology, the science of the mind as dealing through observation, and where possible, through experiment with the growth and development of consciousness or intelligence in dumb animals, children, and adult human beings. It is one branch of that experimental psychology which the German philosopher Lotze was the first to inaugurate.

Gene'va, Ill., a city and county-seat of Kane County, about 33 miles from Chicago, on the Chicago, B. & Q., and Chicago & N. R.R.'s. It was settled in 1832 and was incorporated as a city in 1887. It is a popular residential section for Chicago merchants. The manufactures include windmills, glucose, sadirons, flour, and boxes. The city owns and operates its own electric-light plant and water supply. Pop. (1900) 2,446.

Geneva, Neb., a city and county-seat of Fillmore County, 60 miles west of Lincoln, on the Burlington & M. R. R.R. The State Industrial School for Girls is located here. Pop. (1900) 1,534.

Geneva, N. Y., city in Ontario County, on Seneca Lake and the Seneca and Cayuga Canal; and on the Lehigh Valley and the New York Central R.R.'s; 50 miles southeast of Rochester. Geneva has extensive manufactories of stoves, steam boilers, optical goods, cereals, canned goods, etc. There are also large nurseries and greenhouses here, occupying about 10,000 acres of land. The city is the seat of Hobart College, established in 1822 by the Protestant Episcopal denomination. The Delancey Divinity School, the Delancey School for Girls, and the State Agricultural Experiment Station are located here. Geneva was chartered as a city in 1898 and is governed by a mayor, elected every two years, and a unicameral council. The city owns and operates the waterworks. The assessed property valuation is $6,000,000. The population in 1890 was 7,557 and in 1903 11,228. In the 18th century the Indian village of Kanadesoga was located near the present site of Geneva. General James Clinton attacked and destroyed the village in 1779.

Geneva, Switzerland, a canton, bounded on the north by the canton of Vaud and the Lake of Geneva, and on the east, west, and south by the territories of France. In addition to the territory thus bounded, the communes of Celigny, Le Coudre, and Petit Bois, enclosed by Vaud, belonged to this canton, which is one of the smallest in the Swiss Confederation, the area being only 108 square miles. The whole canton belongs to the basin of the Rhône, and the only streams of importance are that river and the Arve, which joins it a little below the town of Geneva, the capital of the canton. The territory of Geneva having, by the arrangements of the Congress of Vienna, obtained an accession of 15 communes, detached from France and Savoy, was admitted a member of the Swiss Confederation in 1814, and ranks as the 22d canton. A constitution, somewhat aristocratical in its nature, was framed, and continued in force till 1830, when a considerable modification of it took place. In 1841, in consequence of a popular tumult, the original constitution was abandoned for one in which the democratic principle is completely predominant. This new constitution was modified under popular pressure in 1847. All religious denominations are declared to have perfect freedom, but two of them are paid by the state — the Roman Catholics, amounting to rather more than a third of the population, and the Protestant National Church. The language spoken is French. Pop. (1900) 131,674.

Geneva, Switzerland, the capital of the canton of the same name; at the western extremity of the Lake of Geneva, where the Rhône issues, here crossed by several bridges, and

GENEVA, SHOWING MT. BLANC.

dividing the town into two portions. The more important public buildings are the Cathedral or Church of St. Pierre, a Gothic structure of the [illegible] centuries; the town house in the Florentine style; the [illegible], containing a collection of pictures, etc.; the university building, nearly opposite the botanic garden, [illegible] and containing the public library, founded [illegible] and the Museum of Natural [illegible] and science Geneva has long occupied a distinguished place, and it has been the [illegible] of many eminent men [illegible] [illegible] the principles of the Reformation, and chiefly through [illegible] [illegible] influence over the political [illegible] France and Germany. [illegible] commune, [illegible]

Geneva Arbitration, or **Geneva Award**, the settlement of the *Alabama* claims [illegible] [illegible] and the [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] in gold as the [illegible] to be paid by Great Britain to the United States [illegible] [illegible] a year.

Geneva Bible, a translation of the Bible [illegible] [illegible] the first [illegible] [illegible] [illegible] [illegible] [illegible] See BIBLE.

Geneva College, Pa., a coeducational institution [illegible] [illegible] [illegible] Church, [illegible] [illegible] [illegible] grounds and buildings valued at [illegible]; income, [illegible]; president, W. P. [illegible], A.M., D.D.

Geneva Convention ([illegible] and [illegible]), international agreement for mitigating the sufferings of war. The first was initiated by the efforts of two Genevans, a surgeon named Dunant, who wrote a [illegible] description of the [illegible] at the battle of Solferino, and a public-spirited citizen named Moynier, [illegible] [illegible] international conference held at Geneva under the presidency of [illegible] [illegible] statesman. The agreement [illegible] signed [illegible] [illegible] all the European states have since joined in it, and [illegible] [illegible] Ambulances and military hospitals [illegible] [illegible] whether they are occupied by the enemy or not [illegible] [illegible] and their [illegible] [illegible] a house with a sick or wounded soldier [illegible] [illegible] [illegible] to their own country under parole [illegible] hospitals and ambulances, to claim these rights, must carry a uniform flag with a red cross on a white ground as well as their national flag, and the staff must wear a like badge on their arms [illegible] special arrangements to be made by the commanders. In [illegible] a second convention at Geneva adopted a supplementary convention to extend the principles of the first to naval warfare, and amplify the first. It provided [illegible] [illegible] [illegible] [illegible] and their [illegible] with a red stripe; and that [illegible] [illegible] the [illegible] See [illegible]

Geneva, Lake of, or **Lake Leman** (Latin, [illegible]), the largest of the Swiss lakes, [illegible] in the form of a crescent, with its horns pointing south, between France and the cantons of Geneva, Vaud, and Valais; length, [illegible] [illegible] breadth, about [illegible] miles; area, [illegible]

square miles; greatest depth, 900 feet. It is 1,150 feet above the sea. On the north the shore is low, and the ground behind ascends gradually in beautiful slopes. On the south, and particularly at the east end, the shore is rocky and abrupt, and lofty precipices often rise sheer from the water's edge. It contains various species of fish. The water is remarkably pure and of a beautiful blue color. The Rhône, which enters the eastern extremity, a muddy, turbid stream, issues from the western extremity perfectly pellucid, and likewise of the finest blue.

Geneva, University of, a Swiss university founded in 1559, as the Academy of Geneva, and called a university only since 1873. It has 1,100 students, mostly from abroad, and the principal studies are medicine and philosophy. Women have of recent years been admitted on the same conditions as men. It is the European centre of French Protestant culture and influence.

Geneviève, zhĕn-vē-āv, **Saint,** the patron saint of Paris: b. near Nanterre, Paris, 423; d. Paris 3 Jan. 512. When yet very young she took a vow of perpetual virginity and subsequently she went to Paris. The city was about to be deserted when Attila with his Huns broke into France; but Geneviève assured the inhabitants of complete security if they would seek it in fervent prayers. Attila took his course from Champagne to Orleans, returned hence into Champagne without touching Paris, and was defeated in 451. By this event Geneviève's reputation was established. In a time of famine she went along the river Seine from city to city, and soon returned with 12 large vessels loaded with grain, which she distributed gratuitously among the sufferers. Her remains were placed in the subterranean chapel which Saint Denis had consecrated to the apostles Paul and Peter. Clovis by her request built a church over it, which was afterward called by her name, as was also the abbey founded there. Another church, consecrated to this saint, was built near the church of Notre Dame. By a decree of the National Convention, 1791, this edifice was named the Pantheon, but its original name was restored officially in 1851. Her relics, which were preserved in the former till its destruction at the Revolution, are now in the church of Saint Etienne du Mont. Her fête is held on 3 January.

Geneviève, Saint, Duchess of Brabant, wife of Siegfried, count palatine in the reign of Charles Martel (about 750). Being accused by her intendant Golo of adultery during her husband's absence, on his return she was condemned to death; but the vassal to whom her execution was entrusted allowed her to escape, and she lived six years in a cavern upon nothing but herbs. She was finally found, and carried home by her husband, who in the meantime had become convinced of her innocence. This legend is the subject of one of the finest and most perfect of the German popular tales, which appears to have been written by Emmich about 1472. The story has been retold by Tieck and Maler Müller, and dramatized by Raupach.

Genga, Girolamo, jē-rō'lä-mō jĕn'gä, Italian painter and architect: b. Urbino 1476; d. 1551. He was for many years a pupil of Luca Signorelli, whom he assisted in numerous pictures, and also of Perugino; painted a 'Resurrection' in the Church of Saint Catharine of Siena at Rome; and found a generous patron in the Duke Francesco Maria of Urbino, who finally appointed him court-architect. Among his architectural works were the church of St. John the Baptist at Pesaro, the restoration of the palace courtyard there, and the bishop's palace of Sinigaglia. With the versatility of the Renaissance, he wrote on the fine arts, and was a musician and sculptor.

Genghis Khan, jĕn'gĭs khän, or **Jenghis Khan,** Mongol conqueror: b. near the Onon River, Mongolia, 1162; d. 18 Aug. 1227. His father was chief over 30 or 40 clans, but paid tribute to the Tartar Khan. He succeeded his father when only 14 years of age, and made himself master of the neighboring tribes. A great number of tribes now combined their forces against him. But he found a powerful protector in the great Khan of the Karaite Mongols, Oung, or Ung, who gave him his daughter in marriage. After much intestine warfare with various Tartar tribes Genghis was proclaimed Khan of the United Mongol and Tartar tribes.

He now professed to have a divine call to conquer the world, and the idea so animated the spirit of his soldiers that they were easily led on to new wars. The country of the Uigurs, in the centre of Tartary, was easily subdued, and Genghis Khan was now master of the greatest part of Tartary. In 1209 he passed the great wall of China, the conquest of which country occupied him more than six years; the capital, Yenking, now Peking, was taken by storm in 1215 and plundered. The murder of the ambassadors whom Genghis Khan had sent to the king of Kharism (now Khiva) occasioned the invasion of Turkestan in 1218 with an army of 700,000 men; and the two cities of Bokhara and Samarcand were stormed, pillaged, and burned. Seven years in succession was the conqueror busy in the work of destruction, pillage, and subjugation, and extended his ravages to the banks of the Dnieper. In 1225, though more than 60 years old, he marched in person at the head of his whole army against the king of Tangut (southwestern China), who had given shelter to two of his enemies. A great battle was fought, in which the king of Tangut was totally defeated with the loss of 300,000 men. The victor remained some time in his newly subdued provinces, from which he also sent two of his sons to complete the conquest of northern China. At his death in Mongolia, his immense dominions were divided among his four sons. A great part of the empire, however, came into the hands of Kublai, who is considered as the founder of the Mongol dynasty in China. The only memorial of the conqueror now known to exist is a granite tablet discovered among the ruins of Nertschinsk. The inscription in Mongol has been deciphered by Schmidt of Saint Petersburg. It had been erected by Genghis Khan in commemoration of his conquest of the kingdom of Saratogal (better known as Karakitai).

Genii, jē'nĭ-ī, among the ancient Romans, were protecting spirits, who were supposed to accompany every created thing from its origin to its final decay, like a second spiritual self. They belonged not only to men, but all things animate and inanimate, and more especially to places,

and were regarded as effluences of the divinity, and worshipped with divine honors. Not only had every individual his genius, but likewise the whole people. The statue of the national genius was placed in the vicinity of the Roman forum, and is often seen on the coins of Hadrian and Trajan. The genius of an individual was represented by the Romans as a figure in a toga, having the head veiled, and the cornucopia or patera in the hands; while local genii appear under the figure of serpents eating fruit set before them. Quite different are the genii whose Arabic name, *Djinn* or *Jinn*, was translated by the Latin term *genius*, for want of a better word, or from the casual similarity of the sounds. See FAMILIAR SPIRITS.

Genista, jē-nis'ta, a genus of low, branching sometimes spiny shrubs, belonging to the pea family, with simple leaves and yellow flowers. There are about 80 species, a few of which are cultivated for ornament. See BROOM; DYEWEED.

Genius, in Roman mythology, a tutelary deity. See GENII.

Genlis, Stéphanie Félicité Ducrest de St. Aubin, stā-fä-nē fā-lēs-ē-tā dü-krā dė sāṅ ō bāṅ zhŏṅ-lēs, COMTESSE DE, French writer: b. Champcéri, Burgundy, 25 Jan. 1746; d. Paris 31 Dec. 1830. At the age of 16 she was married to the Comte de Genlis, and in 1770 was made lady-in-waiting to the Duchesse de Chartres. In 1782 the Duc de Chartres, afterward known as Egalité, appointed her "governor" of his children, including Louis-Philippe. She wrote a variety of works for her pupils, among others: 'Theatre of Education' (1779–80), a collection of short comedies; 'Annals of Virtue' (1781); 'Adèle and Theodore, or Letters on Education' (1782); 'The Vigils of the Château' (1784). On the breaking out of the Revolution she took the liberal side, but was ultimately compelled to seek refuge (1793) in Switzerland and Germany. When Bonaparte became consul she returned (1799) to Paris and received from him a pension. Her writings fill some 90 volumes. Among them are: 'Précis de la Conduite de Madame de Genlis' (1795); 'Chevaliers du Cygne' (1795); 'Madame de la Vallière'; the romance, 'Mademoiselle de Clermont' (1802); 'Memoirs' (1825); 'Baron d'Holbach's Dinners.' The last contains a great deal of curious but malicious information concerning the freethinkers of the 18th century.

Gennesaret, jĕ-nĕs'a-rĕt, **Lake** or **Sea.** See GALILEE, SEA OF.

Genoa, jĕn'ō-a (ancient GENUA), Italy, a fortified city, situated on the Gulf of Genoa, at the foot of the Apennines, the capital of the province and the most important seaport. While worthy of its title, "Genoa the Superb," as viewed from the sea, it is in reality built awkwardly on irregular rising ground, and consists of a labyrinth of narrow and intricate streets. Of the palaces the most famous are the ducal palace formerly inhabited by the doges, now appropriated to the meetings of the senate; and the Doria, presented in 1529 to the great Genoese citizen Andrea Doria, whose residence it was during his presidency of the republic. The palaces Brignole-Sale, Reale, Durazzo-Pallavicini, Spinola, Balbi-Senarega, and others possess great interest on account of their historical fame and architectural beauty. Many of them contain galleries of paintings: the Brignole-Sale has works by Van Dyck, Rubens, Albrecht Dürer, Paolo Veronese, Guercino, etc. Among the churches are the Cathedral of St. Lorenzo, in the Italian Gothic style; the Church of St. Ambrogio (1589), containing pictures by Guido Reni and Rubens. The marble municipal palace, built in the Late Renaissance style, with a magnificent vestibule, courtyard, and galleries, and the palace of the Dogana must also be mentioned. Genoa has a university, founded in 1243, a library of 116,000 volumes; also numerous technical schools, and institutions of higher education. The hospital, the asylum for the poor (capacity 2,200), the deaf and dumb institution, and the hospital for the insane are among the finest institutions of their kind in Italy. There are numerous excellent philanthropic foundations, as the Fieschi, an asylum for female orphans. The public library contains 50,000 volumes; and there are the Academy of Fine Arts, founded (1751) by the Doria family; the Carlo Felice Theatre, one of the finest in Italy; and the Verdi Institute of Music. Genoa is the commercial outlet of a wide extent of country, of which the chief exports are rice, wine, olive oil, silk goods, coral, paper, macaroni, and marble. The imports are principally raw cotton, wheat, sugar, coal, hides, coffee, raw wool, fish, petroleum, iron, machinery, and cotton and woolen textiles. The annual exports of Genoa are valued at nearly $20,000,000, the imports are returned at more than $75,000,000. Pop. (1901) 234,800.

The history of Genoa may be traced back in legendary traditions to a time preceding the foundation of Rome. It was one of the most considerable cities of the Ligurians, and is mentioned by Livy (under the name of Genua) as being in friendly relations with Rome at the beginning of the second Punic war. It was subdued and partly destroyed during that war by a Carthaginian fleet under the command of Mago. The Romans rebuilt it, and it afterward became a Roman municipium. After the decline of the Roman empire in the West it fell into the hands of the Lombards, and with them became subject to the Franks. After the downfall of the empire of Charlemagne, Genoa erected itself into a republic, and till the 11th century shared the fortunes of the cities of Lombardy.

If Genoa had adopted a wise colonial system she would have held the first rank among the commercial nations at the end of the Middle Ages. After the conquest of Constantinople by Mohammed II. in 1453, the Genoese soon suffered for the aid they had imprudently afforded the Turks. Mohammed took from them their settlements on the Black Sea in 1475, and at length all access to this branch of trade was denied them by the Turks.

While the power and commercial rank of Genoa were attaining their height by means of their foreign trade and acquisitions of territory the city was internally convulsed by civil discord and party spirit. The hostility of the democrats and aristocrats and the different parties among the latter occasioned continual disorders. In 1339 a chief magistrate, the doge, was elected for life by the people, but he had not sufficient influence to reconcile the contending parties. A council was appointed to aid him; yet after all attempts to restore order to the state, there was

no internal tranquillity; indeed, the city sometimes submitted to a foreign yoke in order to get rid of the disastrous anarchy which the conflict of parties produced.

In 1528 the disturbed state regained tranquillity and order which lasted till the end of the 18th century. The form of government established was a strict aristocracy. The doge was elected to be the head of the state. The nobility were divided into two classes — the old and new. To the old belonged, besides the families of Grimaldi, Fieschi, Doria, Spinola, 24 others who stood nearest them in age, wealth, and consequence. The new nobility comprised 437 families. The doge might be taken from the old or new nobles.

Little by little Genoa lost all her foreign possessions. Corsica, the last of all, revolted in 1730 and was ceded in 1768 to France. When the neighboring countries submitted to the French, in 1797 the neutrality which the republic had strictly observed did not save the fluctuating government from ruin. Bonaparte gave to them a new constitution formed on the principles of the French representative system. Two years afterward a portion of the Genoese territory fell into the hands of the Austrians; but the fate of Genoa was decided by the battle of Marengo. A provisional government was established, and in 1802 it received a new constitution as the Ligurian republic and acquired some increase of territory, and had in 1804 a population exceeding 600,000. Its naval force, which was so formidable in the Middle Ages, at last dwindled down to a few galleys and barques; the land force became almost equally insignificant.

On the overthrow of the French empire Genoa was occupied by the British, with whose permission the ancient constitution was re-established. But the Congress of Vienna in 1815 assigned Genoa with its territories to Sardinia, stipulating that it should have a sort of representative constitution. In 1821 it joined for a moment the revolutionary movements of Italy. In the spring of 1849, after the defeat of Charles Albert at Novara and the conclusion of a truce with the Austrians, a revolutionary outbreak took place, the national guards occupied the forts, and the garrison was compelled to withdraw. A provisional government was formed and the independence of the republic was proclaimed. But a large body of Sardinian troops under Gen. Della Marmora, soon appeared before the city; a bloody struggle ensued and the forts and principal points of the city were taken by the royal soldiery. Meanwhile a deputation was sent to Turin, which returned with the amnesty of the king, excluding the chief leaders of the movement, who, however, escaped on board an American vessel. In April the city was disarmed and the monarchical government restored. Following the fortunes of the Sardinian states, Genoa became a portion of the kingdom of Italy. Pop. (1901) 234,710.

Genoa, Gulf of, a large indentation in the north shore of the Mediterranean, north of Corsica, having between the towns of Oneglia and Spezia a width of nearly 90 miles.

Genre (zhŏṅ-r) **Painting,** in art, from the French *genre* (sort or kind), which was originally employed to designate pictures of which the subjects were copied directly from nature, such as landscapes, scenes of every-day life, animals, fruit, and even portraits; in contradistinction to those which were more the product of the imagination, such as historical, religious, and purely ideal paintings. The term is now restricted to denote scenes of every-day life, such as Hogarth and Wilkie loved to depict. A genre painter is not confined to low subjects, nor need his paintings be vulgar in the ordinary acceptation of the word, though the great modern masters in this style, the Dutch, have owed their inspiration and fame to scenes of very humble and often coarse life. This style of painting was not unknown to the ancients. Pyreicus, a Greek painter of the time of Alexander the Great, painted barbers' shops, cobblers' stalls, and the like, and according to Pliny, his pictures were highly prized. In Italy the painters who have worked in this style are Caravaggio, Manfredi, Salvator Rosa, Benedetto Castiglione, etc. But the art received its highest development in the Netherlands; Teniers the younger, Jan Van Mill, D. Ryckaest, Rembrandt, Nicolas Maas, Gerard Dow, Jan Steen, the Van Ostades, Brauwer and Bega, are among the best exponents of the style. In Spain the most notable genre painters are Velasquez and Murillo; and in Great Britain, after Hogarth and Wilkie, already mentioned, come Leslie, Mulready, Maclise, Egg, Millais, Faed, and others. The British school has sought to lend a dignity to the style by the introduction of the dramatic element. See PAINTING.

Genseric, jĕn'sėr-ĭk, king of the Vandals: d. 477 A.D. Under Genseric the Vandals first became formidable at sea, and gained possession of parts of the islands of Sicily, Sardinia, and Corsica. In 455, on the invitation of the Empress Eudoxia, Valentinian's widow, who sought his assistance against Maximus, he landed at Ostia and marched to Rome, which he stormed and gave up to pillage for 14 days. On his departure he carried off the empress herself and her two daughters, one of whom he married to his son Hunnerich.

Gen'tian, the dried rhizome and root of *Gentiana lutea.* This is the yellow gentian of Europe, a tall mountain perennial, growing abundantly in southern and middle Europe and Asia Minor. The chief source of supply to the drug market is collected from Switzerland, southern France, and the hilly portions of Germany. The main constituent of the root is a bitter glycoside, gentiopicrin. It also contains sugar, gums, and salts. The action of gentian is that of a simple bitter and it is used to improve the appetite and thus secondarily affect the general constitution.

Gentile, Da Fabriano. See FABRIANO, GENTILE DA.

Gen'tiles, in Scripture, all the nations of the world, excepting the Jews. In modern usage all the nations excepting Jews and Mormons. In the Old Testament it is the rendering of the Hebrew word *goim,* peoples, nations, the plural of *goi,* a nation, a people. At first it was used as a mere ethnological word, and quite respectfully, but as the Jews became more conscious of their privileges they employed it more and more scornfully of the nations around (Gen. x. 5; Isa. lxvi. 19; Jer. xiv. 22). In the New Testament Gentiles is the rendering of the Greek *ethne,* the plural of *ethnos,* a number of people living together, a nation. St. Peter,

moved by a vision, was the first of the Twelve to preach to the Gentiles (Acts x.), but the Apostle of the Gentiles was Saint Paul (Gal. ii. 15).

Gentry, Meredith Poindexter, American politician: b. Rockingham County, N. C., 1809; d. 1866. In 1839 he was elected to Congress as a Whig, and he was also a representative from Tennessee in 1841–3, 1845–7, and 1847–53. In 1862 and 1863 he was a member of the Confederate Congress. He was a student of political history and well known as a speaker both in and out of Congress, a eulogy of Henry Clay being among his noteworthy public utterances.

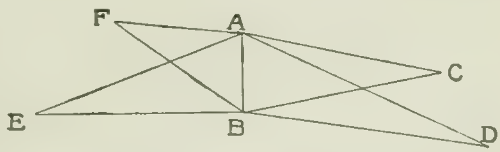
Gentz, Wilhelm Karl, vĭl'hĕlm kärl gĕnts, German painter: b. Neuruppin, Brandenburg, 9 Dec. 1822; d. Berlin 23 Aug. 1890. He traveled in Spain, Morocco, and Egypt, depicted Oriental civilization and the life of the desert with increasing insight and success, and at first turned his attention to the rendering of biblical scenes in the spirit of the actual East. Of the works of this period are: 'Christ in the House of Simon'; 'Christ among the Pharisees and Publicans.' Despite the skill with which he rendered the brilliant light effects peculiar to those regions, his work was slow in making its way. Ultimately, however, he was ranked not at all inferior to the most distinguished French colorists. He was a professor in the Berlin Academy, from 1877 a member of the Senate; and obtained the great medals of Berlin (1866), Vienna (1873), and Munich (1876). In 1873 he visited Palestine to make local studies for his greatest achievement, 'Entry of the German Crown Prince into Jerusalem, 1869,' which was completed in 1876 and hung in the National Gallery of Berlin. Other of his canvases are: 'Mecca Caravan at Prayer'; 'Meeting of Two Caravans in the Desert'; 'Evening on the Nile'; 'Funeral Celebration at Cairo'; 'Serpent Charmer'; 'Alley of Sphinxes in the Thebaid'; 'Bazaar in Algiers'; 'Palm Sunday in Early Christian Times.' He published 'Briefe aus Aegypten und Nubien' (1853).

Genuflection, jĕn-ū-flĕk'shŏn, the act of bending the knee in reverence or adoration. In the Roman Catholic Church the members genuflect when passing before the tabernacle where the Blessed Sacrament is reserved. If the Blessed Sacrament is exposed a double genuflection (on both knees) is usual. Genuflection is used at various times during the church services. The early Christians prayed standing on Sundays, and from Easter till Pentecost, and only bent the knee in sign of penance; hence a class of penitents were known as *Genuflectents.* In the rubrics of the Anglican Church double genuflection, or kneeling, is enjoined in some parts of the service.

Genung, John Franklin, American clergyman and scholar: b. Wilseyville, N. Y., 27 Jan. 1850. He was graduated from Union College in 1870, from the Rochester Theological Seminary in 1875, and from the University of Leipsic, Germany, in 1881; was for a time active in the ministry of the Baptist Church, and later was appointed professor of rhetoric in Amherst College. His publications number: 'Tennyson's In Memoriam: Its Purpose and Structure' (1883); 'Practical Elements of Rhetoric' (1886); 'Hand-Book of Rhetorical Analysis' (1888); 'The Epic of the Inner Life,' a new translation with annotations, of the Book of Job (1891); 'Outlines of Rhetoric' (1893); 'The Working Elements of Rhetoric' (1902).

Genus, jē'nŭs, in zoology and botany, a systematic term applied to any group of species (q.v.) lower in rank than a tribe, sub-family, or family. A genus may be composed of a single, several, or many species. Genera usually differ from species in structural details, while species differ in size or color, or in the structure of some special organ or portion of the body. It is, however, often difficult to draw the line between genera and species. As an example of a genus may be cited *Equus,* or the horse genus, represented by *Equus caballus,* the domestic horse; *Equus asinus,* the ass; *Equus zebra,* the zebra, etc. A genus may be represented by species inhabiting different continents, but usually a genus is confined to a single geographical realm or region. See paragraph on *Classification* in ANATOMY.

Geodesy. The science of measuring large portions of the earth's surface, continents, countries, etc., with a view to determining the form and dimension of our globe and of making maps of extended regions of its surface, differs from surveying (q.v.) in the wider regions which its scope includes, and in the corresponding necessity of more delicate and refined instruments and methods. As an example of the problem it involves: If a map of the United States is to be made, one of the many questions arising would be that of the exact distance on the earth's surface between two cities. This is obviously impossible of measurement in the familiar way with the tape line. To carry out such measurements the method of triangulation must be applied. To do this, two points must be found a few miles apart so situated that the distance between them can be directly measured on the ground, and that from each of them several different points in the region to be surveyed



are visible. Let AB be the two points chosen and C, D, E, F, etc., some of the distant points. The line AB is called the *base line* of the triangulation, and is measured by means of rods closed in wooden cases to protect them from rapid changes of temperature, which are successively placed end to end from the point A to the point B. Recently it has been found that steel tape can be used much more expediently and with all the precision that is required for the purpose. Having found the exact length of the base line, a theodolite is mounted at A and vertical rods or signals are erected at B C, so that the angle BAC can be measured with the greatest possible exactness. Then the theodolite is carried to the point B and the angle is measured in like manner. If practicable the theodolite may also be mounted at C in order to measure the remaining angle of the triangle. The sum of the angles should come out 180°,

this being the sum of the angles of any plane triangle. These three measurements will show any error in the measurement of the angles. Knowing the three angles and of the side of the triangle, the computation of the two remaining sides is a very simple one in trigonometry.

Commonly there will be a number of points, C, D, E, F, etc., which can be determined at the same time. Having done this, any of the lines from A or B to C, or between any two of the other known points, may be used as a new base line and the distance of yet other visible points measured in the same way. These, again, can be used as new base lines, and so on indefinitely. This method is especially expeditious in mountainous regions, where observations can be made from peak to peak at distances sometimes exceeding 100 miles.

Measures of this sort have been carried on or are in progress in most civilized countries. In our own country a system of triangles has been extended from the Atlantic to the Pacific coast, near the parallel of 40° latitude, by the United States Coast and Geodetic Survey. The same survey has carried a line of triangles along the Gulf of Mexico and up the Atlantic coast to the Eastern States, and they are in progress through other parts of the country. The result of these measurements is that the exact position on the earth's surface of a great number of high or prominent points are defined so that they can be laid down on maps. This done, the process of triangulation and surveying can be applied to determine the position of intermediate points, cities, towns, etc., and to determine the course of rivers or valleys.

In order to obtain the most exact result from a geodetic survey of the kind described, the exact form and size of the earth must be known. These cannot be determined in the best way through observations in any one country, but require a combination of the geodetic surveys of various countries as widely separated as possible. With a view of securing co-operation in the solution of the problem, an International Geodetic Association was formed, comprising the United States and the leading countries of Europe. This association, represented by members from the various countries, meets from time to time to carry out the co-operative work of the association, and decide upon the best way of combining the several geodetic surveys.

A fundamental point in which geodesy differs from surveying is in the combination of measurements of the earth's surface, with observations of the stars; the object of the combination is the determination of the curvature of the earth's surface and the size of our globe.

The principle involved will be readily seen by a little careful thought. It is obviously impossible to determine with any exactness the curvature of the earth's surface by observations made solely on that surface. But the surface of the ocean, which is taken as the basic one, is everywhere perpendicular to the plumb-line. It follows that the angle between the directions of the plumb-line at two points will be equal to the curvature of the ocean surface between the points. By skilful astronomical observations it is possible, on any part of the solid earth where an instrument can be mounted, to determine the exact declination in the celestial sphere from which the plumb-line points, which is, in fact, the zenith. The declination of the zenith is the latitude of the place; it follows, that if the latitude of two points north and south of each other is accurately determined, and found to be one degree, for example, the distance between them is the measure of one degree on the earth's surface. This distance can be determined between any two points which are connected by a geodetic measurement. The difference of longitude may also be determined astronomically by telegraph and by geodetic measurement of the earth's surface. The relation between the two measures shows the curvature in the east and west direction.

One of the most difficult questions connected with the figure of the earth is that of the exact ellipticity or flattening of our globe. The precise figure of the earth itself does not admit of definition on account of the irregular outlines of the mountains. Hence, as a basis of all exact statements, geodesy takes, as a standard body representing the earth, the figure that would be formed by the surface of the ocean if the continents were removed so that the ocean would cover the whole globe. It is clear that if the earth did not rotate on its axis, the form assumed by an ocean covering it would be that of a sphere. But, owing to the rotation, the equatorial regions of the earth are expanded and the polar regions contracted so that the ideal form is that of an ellipsoid. If all parts of the earth were of the same density this ellipsoid would be easily determined; but owing to the inequality of density of different parts of the earth, the figure of the ocean itself is not an exact ellipsoid. The best that can be done is to make the calculations assuming it to be such, and to make the best allowance that we can for such small deviations as may be discovered.

When Newton propounded the law of gravitation, the flattening of the earth at the poles was seen to be a natural result. But the French contended that the earth was actually elongated toward the poles. To settle the question one of the most celebrated expeditions in geodetic history was sent to Peru to measure an arc of the meridian near the equator, and another expedition went to Lapland to measure one near the poles. The results showed Newton's theory to be correct, and since that time there has been no doubt on the subject. But the difficulty of determining the exact length of a degree and the irregular variations in the figure of the earth, which we shall soon mention, are such that the determinations by geodetic measures have not been altogether satisfactory. Another method is afforded by the force of gravity, as determined by the length of the seconds pendulum. It is well known that gravity is less in the equatorial regions of the earth than at the polar regions, from two causes. One is the centrifugal force of the earth's rotation, and the other is the greater distance of the centre of the earth's surface at the equator. The result is that a clock pendulum, swinging exact seconds near the pole, would lose several seconds a day when taken to the equator; hence, a pendulum which would beat exact seconds must be made continually shorter as we approach the equator. The determination of its length in various latitudes thus becomes an important problem in geodesy. When it is known, the ellipticity or flattening of the earth may be determined from it.

What makes all the problems associated with this so complex are the small irregularities in the direction and force of gravitation wherever measures and determinations have been made. It is always found that when the latitudes of places are determined by the direction of the plumb-line, which is the only astronomical method, they seldom agree with the differences between the places as determined by geodetic measurements. The reason is, that the plumb-line is deflected by the attraction of mountains and denser portions of the interior of the earth which do not admit of exact computation. These irregularities are greater in mountainous regions, in the Himalayas sometimes rising to 30 seconds. But even in plain countries deviations of 2 or 3 seconds are found. The errors arising from these deviations would not be important in themselves, the difficulty being that they operate like a small error in a foot rule when the latter has to be used for measuring a very long stick of timber. In such a case an error even so small as one eighth of an inch in the rule would amount to an error of a foot in measuring a pole 100 feet long. As the measurement of a whole continent, even of the earth itself, has to start from short base lines, the error may be multiplied many fold in the final result.

SIMON NEWCOMB.

Geodetic Surveying. See SURVEYING.

Geoffrey (jĕf'ri) **of Mon'mouth** (called also GEOFFREY AP ARTHUR), English chronicler: b. probably at Monmouth about 1100; d. Llandaff 1152 or 1154. According to Leland he was educated at Monmouth, in a convent of the Benedictines, whose society he entered. He was afterward made archdeacon of Monmouth, whence he was, in 1152, raised to the bishopric of Saint Asaph. The state of affairs in North Wales induced him to retire to the court of Henry II. He wrote various works; but his 'Historia Regum Britanniæ' is his most important production. This is now known to be, as the compiler states, chiefly a translation from Armorican manuscripts discovered in Brittany by Walter Calenius, an archdeacon of Oxford. It contains a pretended genealogy of the kings of Britain from the time of the fabulous Brutus, or Brute, the Trojan, to the death of Cadwallader, king of Wessex, in 688. It was first printed by Ascenius, at Paris, in 1508. An English translation by Aaron Thompson, at London in 1718, was reprinted in Bohn's Antiquarian Library, 1848. We are indebted to Geoffrey for preserving, and perhaps reconstructing, the legends of Arthur and his knights, the exquisite fiction of Sabrina introduced into Milton's 'Masque of Comus,' the subject of Shakespeare's 'King Lear,' and many of the finest episodes in Drayton's 'Polyolbion.'

Geoffrin, Marie Thérèse Rodet, mä-rē tā-rēs rō-dā zhō-frăñ, the holder of a noted Parisian literary salon: b. Paris 2 June 1669; d. there 6 Oct. 1777. By the grace and vivacity of her manners, aided by a refined and cultivated taste, she drew around her all the fashion, wit, and learning of Europe. Early left a widow, with an opulent fortune, her charities to the poor, and her benevolent aids to literature, endeared her as much to society as her wit and virtue delighted. In her house the best society in Paris was assembled. Cultivated minds of every description found access to her. None could there claim a preference: the mistress of the house herself was far from desiring any precedence; she was only amiable and animating. Three of her friends, Thomas, Morellet, and D'Alembert, dedicated particular writings to her memory, which, with her treatise, 'Sur la Conversation,' have been republished.

Geoffroy Saint Hilaire, Etienne, ā-tē-ĕn zhō-frwä săñ-tē-lăr, French naturalist: b. Etampes, France, 15 April 1772; d. Paris 19 June 1844. He was educated at the colleges of Navarre and Lemoine, and became a favorite pupil of Haüy. At the age of 21 he obtained the chair of zoology in the Parisian Jardin des Plantes. As a member of the Egyptian expedition in 1798 he founded the Institute of Cairo, and returned about the end of 1801 with a rich collection of zoological specimens. In 1807 he was made a member of the Institute, and in 1809 professor of zoology at the Faculty of Sciences. He devoted himself especially to the philosophy of natural history. Among his principal works are: 'The Principle of Unity in Organic Composition' (1828); 'Philosophy of Anatomy' (1822); 'Natural History of the Mammifers' (1819–37); 'Ideas of Natural Philosophy' (1838).

Geoffroy Saint Hilaire, Isidore, French physiologist and naturalist, son of the preceding: b. Paris 16 Dec. 1805; d. there 10 Nov. 1861. He devoted himself to natural history, and in 1824 was appointed assistant to his father at the Jardin des Plantes. He was elected to the Academy of Sciences in 1833, and afterward became successively inspector-general of the university, member of the council of instruction, and professor of zoology at the Academy of Sciences. One of his chief works, 'History of Anomalies of Organization in Man and the Animals' (1832–7), adds valuable confirmation to the theories of his father. He was the means of founding the Acclimatization Society of Paris. He paid much attention to the domestication of foreign animals in France, as appears from his treatise 'Domestication et Naturalisation des Animaux utiles' (1854), and advocated the use of horse flesh as food in his 'Lettres sur les substances alimentaires' (1856). He also published an excellent life of his father under the title 'Vie, Travaux, et Doctrine scientifique d'E. Geoffroy Saint Hilaire' (1848).

Geognosy, jē-ŏg'nō-sĭ, a name under which are included those branches of geology which have to do strictly with the elements of which the earth, the sea, and the air are composed, and their various combinations. Hence it more particularly deals with rocks and rock-forming materials, and embraces much that is included in the study of petrography (q.v.). See GEOLOGY.

Geographer of the United States. The Continental army in the Revolution had a geographer to make maps and plans; and on 4 May 1781 Thomas Hutchins (q.v.), a protégé of Franklin's, was on his recommendation appointed geographer to the Southern (Greene's) army. After the peace, Hutchins was retained as United States geographer, in connection with the surveys of the western lands ceded by the

States; the first official note of the office is in the draft of the general land bill reported 26 April 1785, where it is referred to as existing, and shortly afterward Hutchins is referred to as occupying it. He was to supervise the State surveyors appointed by Congress, suspend them if unsatisfactory, and report to Congress. He was reappointed in 1788, for two years, but died the next year.

Geograph'ical Conquests. The 3d century after the discovery of America drew to its close with a veil of darkness still shrouding half the globe from the eye of civilized man. A Strabo or a Ptolemy, if questioned in 1800 as to how much of the earth's surface he could describe with accuracy, would have had to confess that he was quite familiar with only one of the grand divisions, and that one embracing only a tithe of the land of our planet. He might perhaps have claimed that he could make a tolerable map of South America, whose interior had been partly opened up by the zeal of the Jesuit missionaries. It would, however, have been full of great voids representing regions unknown to him. He would have been able also to construct a map of Asia, approximately reproducing its main features, but his outlines would have been merely the framework of blurred and empty pictures. The Himalayas had not been measured — the Andes figuring as the highest mountains on the globe. There was a boundless area within the Chinese empire untrodden by Europeans. In Asiatic Turkey, Persia, and in Afghanistan, in Turkestan, and the Pamir, there were whole regions removed from the ken of cartographers. Scant information existed regarding Japan, Farther India, and the Malay Archipelago; next to nothing was known about Korea, and the interior of Arabia was almost a blank. Australia was still floating as a cloud on the horizon. Most of the lands north of America had not yet been discovered, and the Antarctic realm had barely been touched.

The accurate knowledge of Africa was limited in the main to a narrow strip along the coast. As for the interior, comprising about one fifth of the earth's land surface, geographical learning had hardly begun to outgrow its mediæval estate. Cartographers had been groping their way amid the confused reports of traders, slave dealers, and missionaries. The feature of Equatorial Africa regarding which the most correct conjecture had obtained for centuries, was the source of the Nile, which river, in accordance with the teachings of Ptolemy and the old Arab geographers, was represented on the maps as issuing from some lakes in the heart of the continent, fed by the Mountains of the Moon. Geographers knew of a great river that flowed by Timbuktu, the Queen of the Desert, and which they called the Niger, a name handed down from the time of the ancients. It had long been supposed that this stream had a western course and that the Senegal and Gambia formed its delta. A counter theory was that it flowed east to a large lake, a view based in part on vague reports about Lake Tchad. Still another theory regarded the Niger as one of the great arms of the Nile. The Kongo was known only in the last portion of its interminable course, though as far back as the 17th century the opinion had been entertained that it issued from the same quarter of the continent as the Nile. The Sahara remained untraveled by Europeans, except near its margin, and the great lakes of Africa were known only through tradition or vague report.

In North America, the region between the Mississippi and the Pacific and north of New Mexico still belonged in great part to the realm of fancy. British America remained in great part unexplored, and the coast of Alaska had barely been grazed. There were whole regions, like the Adirondack wilderness, included within the bounds of the original States of the American Union, which were still sealed to geographers.

Nearly 300 years after the tracing of the coast line of Africa was completed by the voyages of the Portuguese, the systematic exploration of the interior may be said to have commenced in 1788 with the foundation in London of the African Association, an event which inaugurated a new era in the history of geographical discovery. This society had the good fortune to command almost at the start the services of the intrepid Scotchman, Mungo Park. Before this, it is true, the pioneer of modern African exploration, Sir James Bruce, had made his memorable journey along the Blue Nile, and the ornithologist, Le Vallant, had traveled in the hunting grounds of South Africa. Just before we hear of Mungo Park, the record of discovery also tells of a narrow wedge driven toward the heart of the continent in the journey of Browne from Assuan to Darfur. The African Association assumed for one of its first tasks the unraveling of the mystery of the Niger. The journeys of Mungo Park (who perished in the stream in 1806), of Clapperton and Denham, and of Lander, covering together the period from 1795 to 1830, revealed the course of the river. The French, meanwhile, explored the Senegal and Gambia. At this time English explorers began to push from the Guinea coast into the warlike kingdoms of Ashanti and Dahoney. In 1826 the ill-fated Laing, and in 1828 Caillié, succeeded in reaching Timbuktu, that mysterious seat of Islamism which had for centuries fascinated geographers. (See FIGS. 1 and 2.)

The close of the 18th century was the beginning of a new era in the annals of American exploration. The travels of Alexander von Humboldt between 1799 and 1804 in the basins of the Orinoco and Magdalena, and in the Andes and Mexican Cordilleras, mark an epoch in the history of geography and natural science. His work was taken up and extended to other regions, especially Brazil, by eminent naturalists like Maximilian of Wied, Spix, Martius, Auguste de Sainte-Hilaire, Orbigny, and Pöppig. These had worthy successors in the brothers Schomburgk (British Guiana), Darwin (Patagonia, Tierra del Fuego), Avé-Lallemant (Brazil), Tschudi (Andes, Brazil), Castelnau (Brazil, Bolivia, Peru), and Burmeister (Brazil, Argentina).

By the acquisition of the Louisiana territory in 1803 the United States came into possession of a boundless domain, in great part as far removed from the knowledge of white men as the heart of Africa. (See FIGS. 5 and 6.) An exploring expedition was immediately sent into this *terra incognita* under Lewis and Clark, who

Fig. 1.—Africa as known in 1800. The darkened portions in this and succeeding maps show the unexplored areas.

Fig. 2.—Africa as known in 1900.

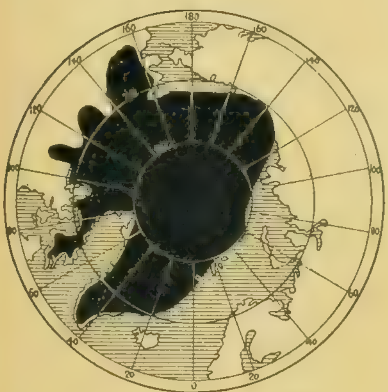


Fig. 3.—Arctic Regions as known in 1800.

proceeded up the valley of the Missouri, crossed the divide of the Rocky Mountains, and followed the Columbia down to the sea. The explorations of Pike, Long, Bonneville, Catlin, Nicollet, and Frémont, the opening of overland routes to Utah and California, and the government survey for a Pacific railway made deep rifts in the trans-Mississippi region; but its greatest wonders were to remain enshrouded till the tide of colonization had begun to sweep over the whole area. It was not till 1832 that the Mississippi river was traced to its source by Schoolcraft.

The exploration of the Arctic regions, in the hope of finding a north water route for the trade with the East, had lost much of its fascination by the 18th century. Russia alone prosecuted it systematically in the course of that century, accomplishing a great work in tracing the coast line of Siberia. About the beginning of the 19th century the idea of a Northwest Passage was revived in England and the dream of reaching the pole began to be entertained. (See FIGS. 3 and 4.) A great and persistent onslaught on the frozen North was inaugurated in 1818. The labyrinth of islands, peninsulas, and ice-bound passages north of the American continent yielded up its intricacies to the assaults of Parry, the two Rosses, Sir John Franklin (to whose tragic end Arctic discovery owed much of its rapid progress), McClure, Kane, McClintock, and Hayes. The exploration of Arctic British America was prosecuted on land with heroic energy by Franklin, Back, Richardson, Beechey, Dease, Simpson, and Rae. Parry in an attempt to reach the pole in 1827 dragged his sledges over the floating ice fields to the parallel of 82° 45′, eclipsing all previous records by more than a degree of latitude. In 1831 James Clark Ross solved the mystery of the position of the north magnetic pole, which he located in the peninsula of Boothia. McClure entered the Arctic Ocean through Bering Strait in 1850, proceeded east, was beset for years in the ice, joined hands in 1854 with an expedition which had come in the opposite direction, and thus carried off the laurels of the Northwest Passage. While a great breach was being made in the Arctic fastnesses, Bellingshausen, Weddell, Dumont d'Urville, Sir J. C. Ross, Wilkes, and others extended geographical discovery into the Antarctic regions. Ross discovered Victoria Land, with its active volcanoes, and in 1842 advanced beyond the 78th parallel. During this same period the cruel depths of Australia, whose coast had been explored by Flinders in 1801–3, were invaded by Sturt, Eyre, and the ill-fated Leichhardt.

A flood of light was thrown on the geography of Northern and Central Asia in the first half of the 19th century by the journeys of Ermann, Humboldt, Middendorf, Huc (who entered Lhassa, the holy city of Tibet), and others; while men like Webb, Moorcroft, and Wood scaled the heights of the Himalayas and the Pamir, and reached the head streams of the Indus, Ganges, and Amu Daria. From 1848 Mount Everest, with the 29,002 feet given to it by the trigonometrical measurement of Sir Andrew Waugh, figured as the highest point on the globe. Among the naturalists who were attracted to the Himalayas, the name of the botanist Hooker stands pre-eminent. The most distinguished traveler in southwestern Asia in the early part of the century was Burckhardt, who succeeded in entering the holy places of Mecca and Medina. In 1829 Ararat was ascended by Parrot. In 1832–3 Alexander Burnes performed his famous ride from India to Bokhara. The travels of Crawfurd and MacLeod in the second quarter of the century dispelled in part the obscurity hanging over farther India. Between 1835 and 1849 the naturalist Junghuhn explored Java and parts of Sumatra. Among his successors in the Malay Archipelago were St. John and Wallace.

Down to the time of the French Revolution, Europe had hardly dared to cast a covetous eye on the interior of Africa. Portugal, England, and France held sway at a few stations along the coast. The sturdy Boers, near the Cape of Good Hope, alone represented actual colonization by Europeans. The Revolution brought in its train Bonaparte's conquest of Egypt, the first great onslaught on African territory on the part of Christendom in modern times. The consequences of the French domination, brief as it was, were far-reaching in the loosening of Turkey's hold upon that country. Another result of the wars of the Revolution was the supplanting of Dutch dominion at the Cape by that of England. An army of ardent missionaries now made their way into the interior of South Africa. While England was laying the foundations of an empire at this end of Africa, France suddenly invaded the north and conquered Algeria (1830–48). A few years before this invasion, Mehemet Ali, viceroy of Egypt, brought Nubia and Kordofan under his sway. This ambitious potentate, who, for the first time since the days of Saladin, made the aggressive power of Africa felt in another continent, in his role of modernizer of Egypt, sent various scientific expeditions to explore the Nile, which was now traced almost to the equator. To this period of African exploration belong the travels of Rüppell, the brothers Abbadie, Beke, and Krapf in Abyssinia.

With the middle of the 19th century commences an extraordinary era in the history of geographical discovery. The world begins to close in upon the dark interior of Africa which is assailed on every side, and in the course of a generation the great features of the continent are unfolded almost in their entirety. In 1847 the German missionaries Krapf and Rebmann discovered the snow-capped peaks of Kilima-Njaro and Kenia, near the equator. In 1849 Livingstone discovered Lake Ngami, in the heart of South Africa, at a distance of 1,000 miles from Cape Town. In the course of the next seven years he extended his explorations to the Upper Zambesi, of which mighty stream hardly anything had hitherto been known, followed it up, struck out west along the edge of the Kongo basin (a circumstance unknown to him), made his way to the Portuguese possessions on the Atlantic, then, turning back, followed the Zambesi down stream, discovered the Victoria Falls, the rival of Niagara, and came to the shores of the Indian Ocean. While Livingstone was drawing a luminous trail across South Africa from sea to sea, Heinrich Barth was lifting the veil from the depths of the continent on the other side of the equator by his extraordinary journeys in the west half of the Sudan. In the sixth and seventh decades of the century large accessions were made to the knowledge of the

Nile basin and the surrounding regions, including Abyssinia, by the travels of Petherick (who explored the basin of the Bahr-el-Gazal), Munzinger, Beurmann, Heuglin, and others. In the meanwhile the French were pushing into West Africa on the side of Senegambia, Du Chaillu traveled in the country back of the Gabun and through the wilds of the Ogowe, the home of the gorilla and the pygmy Obongo; Burton scaled the peak of Kamerun, and Von der Decken explored what is now British East Africa.

Just as Barth was emerging from the scorching suns of Central Africa, laden with the knowledge of countless peoples, in another continent three equally intrepid Germans proceeded to explore the most elevated region of the globe. The brothers Schlagintweit crossed the Himalayas and the Karakoram, traversed the lofty plateau of Tibet, and surmounted the Kuenlun, reaching heights to which no traveler had ever climbed.

Soon after Livingstone's traverse of South Africa, the beginning was made of those discoveries which unraveled the most interesting problem presented by the geography of that continent. In 1858 Burton and Speke, despatched by the Royal Geographical Society in quest of a great reservoir of fresh water which was believed to exist somewhere in the region whence the Nile issued, discovered Lake Tanganyika. Before the close of that year, Speke discovered a still larger lake, the Ukerewe, or Victoria Nyanza, which he assumed to be a reservoir of the Nile, though as yet its outlet remained to be found. To what river system, if any, Lake Tanganyika belonged was a problem which was to wait still many years for a final solution. In 1859 Livingstone came to the shores of a third great lake, the Nyassa, a feeder of the Zambesi. Within the next five years the question of the sources of the Nile was approximately settled by the explorations of Speke, Grant, and Baker. The last named, ascending the river from Egypt in 1864, discovered the west of the Nile reservoirs, the Mwutan Nzige, or Albert Nyanza. What Ptolemy had laid down on his famous map 1,700 years before was found to be substantially correct, and the discovery later on of snow-clad mountains near the Albert Nyanza, culminating in Ruwenzori, substantiated what the Greek had taught regarding the Mountains of the Moon.

The problem of the Nile was closely interwoven with that of the Kongo, the greatest mystery that still confronted geographers outside of those presented by the polar regions. The Nile question, indeed, could not be regarded as completely settled till the watershed between the two rivers had been determined. Of the Kongo basin, equal in extent to that of the Mississippi, but a mere fraction was known to the world. A boundless maze of tropical forests and rivers had thus far escaped the eye of Europeans. Geographers were not even agreed as to whether the Kongo issued from the heart of the continent or whether it was not rather in the nature of a coast river. Livingstone applied himself with heroic resolution to the task of ascertaining the parting of the waters that found their way to the Mediterranean and those that flowed toward the Atlantic. In 1867–8 he discovered the Luapula, the east head stream of the Kongo, and its two large reservoirs, Mweru and Bangweolo, and in 1871 stood on the banks of the great river that hurries past Nyangwe, but not possessed of the information that would assure him beyond doubt that it could be no other than the Kongo.

During these years wide explorations were made in Central Africa, north of the equator, by Rohlfs, Nachtigal, and Schweinfurth. Nachtigal, a worthy successor of Heinrich Barth, succeeded in making his way into Wadai, a Mohammedan state in Sudan, a goal the pursuit of which had cost the lives of two eminent explorers, Vogel (1856) and Beurmann (1863). Schweinfurth penetrated into the cannibal regions west of the equatorial Nile, and in 1871 came to the Welle, whose west course convinced him that he had traveled beyond the bounds of the Nile.

These journeys were coincident with a remarkable epoch in the geographical annals of America. The explorations of Dall revealed the extent of the Yukon; the mountain systems of the West were explored by Wheeler, Whitney, and Hayden; Powell discovered the grand cañon of the Colorado; Washburne and Hayden made known the marvels of the Yellowstone. The knowledge of British America was at this time greatly extended by the travels of Bell, Selwyn, Dawson, and others. Simultaneously with the exploration of the mountains of North America, the geological structure of the Andes was laid bare by Reiss and Stübel, who ascended the volcano of Cotopaxi to its summit.

While the rest of the world was engaged in prying open the recesses of the continents, the Russians were displaying extraordinary activity in the exploration of their vast Asiatic domain and the regions bordering on it. In the first 15 years of the reign of Alexander II., Semyenov, Valikhanov, Radlov, Ostensacken, Syevertsov, Fedtchenko, and Kaulbars assailed that mighty mountain barrier composed of the Altai, Alatau, Tian-Shan, Alai Tagh, and the Pamir, which shuts off the elevated desert region of Central Asia from the plains of western Turkestan and Siberia. During the same period Shishmarev, Mattussovski, and Pavlinov penetrated into Mongolia, and Palladius into Manchuria. The Russian advance into Central Asiatic highlands met with a prompt response from beyond the Himalayas, whence Hayward, Shaw, and Forsyth pushed into eastern Turkestan, while the pundit Nain Singh made a memorable traverse of Tibet.

When Japan and China, soon after the middle of the 19th century, opened their portals to the world, the work of exploration, previously inaugurated by dauntless missionaries and naturalists, proceeded with a new impetus. Great journeys were made in China by Blakiston, Pumpelly, Ney, Elias, Bastian, Cooper, and Richthofen, who belong to the foremost ranks of Asiatic explorers. In the decade beginning with 1861 explorations were made in the Caucasus, by Radde, in northern Arabia by Palgrave, and in Turkestan by Vámbéry and Lagrée, and Garnier traced the course of the Mekong as far up as the Chinese province of Yunnan. Contemporaneous with these travels were the remarkable journeys performed in Australia by Burke and Willis, MacKinlay, Stuart, and Forrest, whose exploits were emulated by Giles and Warburton.

The year 1871 is memorable in the history of geographical discovery for the dramatic episode of the finding of Livingstone by Stanley. The meeting by the waters of Tanganyika was followed by the exploration of the north end of the lake which was found to have no outlet in that direction. Livingstone then returned to the scene of his recent labors, the Luapula-Lualaba basin. On 1 May 1873, he expired on the shores of Lake Bangweolo, which he had discovered and which he had become convinced belonged to the Kongo system. In 1874 Cameron discovered that Lake Tanganyika was connected by an outlet, the sluggish Lukuga, with the river formed by the Lualaba and Luapula. This river (which Livingstone had reached in 1871 at Nyangwe) was found by Cameron to flow at too low a level to admit of its belonging to the Nile system. This fearless traveler was prevented by the hostility of the natives from descending the stream and verifying his belief that it was the Kongo. It was reserved for the dauntless spirit of Stanley to bring the mightiest of African rivers within the ken of mankind. In November 1876 he embarked at Nyangwe in a fleet of canoes, and performing an unprecedented voyage which twice carried him across the equator, he reached the tides of the Atlantic in August 1877. And now came the great task of exploring the Kongo tributaries, which enlisted the energies of Stanley, Capello and Ivens, Buchner, Pogge, Wissman, Grenfell, Wolf, Brückner, and Van Gèle.

While the veil was being lifted in this quarter, new light was thrown on the regions west of the Upper Nile by the travels of Junker, Casati, Gessi, and Lupton, the country between the Ukerewe and the coast was opened up by Fischer, Thomson, and Johnston, the naturalist Emil Holub traveled in the Zambesi region, and the explorations of Brazza between the Ogowe and the Kongo laid the foundations of a new French colony. Between 1878 and 1881 Serpa Pinto made his traverse of South Africa, Oskar Lenz performed a journey from Tangier to Timbuktu and thence to the Senegal, and Matteuci crossed from Egypt to the Gulf of Guinea. At this time began the extraordinary career of Emin Bey (Eduard Schnitzer), administrator, explorer, naturalist, and linguist, in the region of the equatorial Nile. This heroic commander, the peer of the great Gordon, was cut off for years from the world by the Mahdist uprising, till at last Stanley succeeded in reaching him by way of the Kongo and Aruwimi, an exploit which recalled the days of the Conquistadores. In 1887 the Rudolf lake was discovered by Teleki. In 1889 Meyer reached the summit of Kilima-Njaro.

During the years which revealed the sources of Africa's greatest rivers the exploration of the mighty tributaries of the Amazon was prosecuted by Chandless. A little later Crevaux won laurels in the same field, and to him succeeded Karl von den Steinen and Ehrenreich.

The decade which witnessed the solution of the Kongo problem, the last great mystery that had remained hanging over the equatorial zone, was marked by renewed activity in Arctic research. The passage leading north from Baffin Bay, beginning with Smith Sound, appeared to promise access to an open polar sea, the theory of whose existence had been put forth by Kane. The American expedition under Capt. Hall in 1871 proceeded up this channel, and the splendidly equipped British expedition under Sir George Nares in 1875 followed in its wake; but Kane's theory was not verified. Some of Nares' men in 1876 reached the parallel of 83° 20′, eclipsing Parry's record by more than half a degree. Lieut. Lockwood of the ill-starred Greely scientific mission in 1883 made a farther gain of four minutes. In 1873 the Austrian expedition of Weyprecht and Payer discovered Franz-Josef Land. In 1878–9 Nordenskjöld immortalized himself by accomplishing the Northeast Passage.

While Stanley and his successors were opening up the exuberant forest realm of Equatorial Africa, the arid expanse of Central Asia, stretching from the Pamir on the west to the highlands of Manchuria on the east, and embracing the desert of Gobi (Shamo), the Tarim basin, with the Takla Makan desert, and the ranges of the Tian-Shan, Kuenlun, Altyn Tagh, and Nan-Shan, was attracting the most intrepid explorers from all parts of the world. This illustrious roll includes the great Przhevalski (whose name is borne by the former town of Karakol, in Turkestan, where he died in 1888); Sosnovski, Mushketov, Kostyenko, Potanin, Regel, the pundit Krishna (who removed the long-existing doubt regarding the identity of the Sanpo and Brahmaputra), Pyevtsov, Bell, Bogdanovitch, Roborovski, Carey, the brothers Grum-Grzhimailo, Rockhill, Younghusband, Bonvalot, and Henry of Orleans. These had distinguished successors in the last decade of the century in Dutreuil de Rhins, Littledale, the young Swedish geologist Sven Hedin, Obrutchev, Futterer, Holderer, and Deasy. Among the host of ardent explorers who have traveled in China since 1875 are Sosnovski, Baber, Gill, Széchényi (son of the great Hungarian patriot, Count Stephen Széchényi), Kreitner, Easton, Hosie, Colquhoun, Henry, and Younghusband. It is only since 1880 that the geography of Korea has emerged from its obscurity.

In the last quarter of the 19th century the dimensions of the unknown in Alaska, the Northwest Territories, and Labrador were vastly reduced by the explorations of Muir, Allen, Schwatka, Dawson, Ogilvie, Russell, Low, and others. In 1888 the first crossing of Greenland's great ice cap (in its southern part) was accomplished by Nansen. In 1892 Peary and Astrup made a sledge journey of more than 1,000 miles over the northern end, and determined the extension of the island in that direction. In 1893–5 the gap between the North Pole and the highest latitude ever before reached (Lockwood's 83° 24′ in 1883) was bridged almost half over by Nansen's drift voyage and sledge journey, which carried him to the parallel of 86° 14′. This record was eclipsed in 1900 by the expedition of the Duke of Abruzzi, which reached 86° 33′. The results of these expeditions render it improbable that any extensive land mass remains undiscovered within the Arctic Circle. As the physical conditions prevailing at the North Pole cannot be materially different from those observed in the near vicinity, the reaching of the pole itself may now be regarded as a goal belonging to the realm of adventure rather than to that of scientific discovery.

In the same year in which Peary and Astrup crossed the fathomless ice cap of Greenland the gigantic glaciers of the Karakoram were ex-

plored by Sir William Martin Conway, who climbed to an elevation of about 23,000 feet, eclipsing the record of all former travelers. In 1897 Aconcagua, probably the loftiest peak of the Andes, was scaled to its summit by Zurbriggen, the Swiss guide, and Vines, the geologist of Fitzgerald's expedition, the elevation obtained for it by barometric measurement being 23,080 feet. In 1898 Conway accomplished the ascent of Illimani, one of the rivals of Aconcagua.

At the close of the 19th century the attention of the world was once more turned, after a long interval, to the Antarctic regions. The British expedition under Borchgrevink succeeded in locating the south magnetic pole, and attained to the parallel of 78° 50′, surpassing by 40′ the «farthest south» achieved by Ross in 1842. Within the Antarctic Circle remains by far the greatest unknown area on the globe. Outside of the polar realms the physical map of our planet, barring minor details, is nearly complete. When the 19th century opened, geographical science had half a world to conquer. At its close this conquest may be said to have been well-nigh achieved.

Geographical Distribution of Animals. It is a familiar fact that certain kinds of animals dwell in very limited districts, others in larger areas, perhaps throughout a whole continent; but that any considerable change in one's location on the face of the earth brings him into contact with a more or less different fauna. This is the more certain and conspicuous if a sea or mountain range or desert intervene between the two points of observation. In general it is plain that species of animals of all sorts have, as a rule, a comparatively limited habitat; genera often a more extended one; while the higher groups may have a wide or even cosmopolitan range. These areas of life for similar animals are more likely to spread in directions of latitude than of longitude, so that the northern hemisphere (*Arctagæa*) is more different faunistically on the whole from the southern one (*Notogæa*) than are, for example, Europe and the United States. The science which deals with the causes and principles of this body of facts is called Zoogeography, under which head the subject is considered in detail.

Geographical Societies are associations formed with the view of obtaining and disseminating geographical knowledge. This is attained, in the first instance, by members undertaking distant travels, at their own expense in some cases, in others assisted by the funds of the society or grants from government; and, in the second instance, by lectures delivered and works issued under the auspices of the society, or by papers read and commented on at the periodical meetings. In point of seniority the first of these associations is the Société de Géographie of Paris, founded in 1821. The German Gesellschaft für Erdkunde held its first sittings in Berlin in 1828, under the presidency of Ritter, and has counted among its members many of the most famous of modern geographers. By far the most important of these institutions, however, is the Royal Geographical Society, established in London in 1830. The principal travelers and geographers of Great Britain, or indeed of the world, are or have been connected with this society, and such names as those of Livingstone, Burton, Baker, Speke, Barth, Wallace, Cameron, Stanley, Thomson, Johnston, Bent, Curzon, Markham, Nansen, and many other well-known travelers, are to be found attached to papers in its 'Journal' (1831–80, 50 vols.) and 'Proceedings' (ceased in 1892), or in the 'Geographical Journal,' which it has issued since 1893 in monthly parts, and which includes the society's proceedings. It has a capital of $200,000, and large sums are devoted annually to aid the cause of geographical research, or as awards and recognition of services rendered to the science. The Russian Geographical Society, founded at St. Petersburg in 1845, has greatly extended our knowledge of Central Asia and Asiatic Russia. Following the lead of other nations, Italy has her Società Geografica, founded at Florence in 1867, and issuing an annual 'Bollettino.' The American Geographical Society (q.v.) was founded at New York in 1852. The Royal Scottish Geographical Society was founded in 1884. It publishes an excellent monthly magazine, and its members number between 1,500 and 1,600. The Royal Geographical Society has a membership of between 3,000 and 4,000.

Geographical Society of Baltimore, organized in 1902 for the study of geographical science. It acquired over 1,000 members during the first year of its existence. Daniel C. Gilman was the first president of the Society.

Geographical Society, The American, a society established in 1852 to encourage geographical exploration and discovery and to disseminate new geographical information. See AMERICAN GEOGRAPHICAL SOCIETY.

Geographical Society, The National, an American organization with headquarters at Washington, D. C. It was formed in 1888, and offers annual lecture courses in Washington upon popular geographical subjects. The 'National Geographic Magazine' is published monthly by the Society, which had 3,000 members in 1902.

Geographical Society of Philadelphia was organized in 1891, and in 1893 a charter was granted to the Geographical Club of Philadelphia, of which Angelo Heilprin was the first president. The present title was resumed in 1897. The Society confers annually the Elisha Kent Kane gold medal, as a reward for geographical work. In 1902 the Society had 430 members.

Geographical Society, Royal, was founded at London in 1830 to aid in scientific research in geography, and received a charter in 1859. It has published numerous papers, books, and magazines, and expended large sums of money to encourage research. See GEOGRAPHICAL SOCIETIES.

Geography, by derivation, means «description of the earth.» Humboldt's interpretation, which, beyond the gathering of data for mapping the topographical and drainage features of a region, added a study of meteorological and climatic conditions, of the character of soils, and of the distribution of life both animal and vegetable, was the first true impulse given to modern geographical research. For a comprehensive knowledge of the earth the aid of all branches of natural science is sought. Geography, while it is specifically the science or knowledge of the earth, is dealing with phenomena and study-

ing laws which belong to the universe. One of its important functions is the investigation of the reciprocal relations existing between man and his physical surroundings. The average text-books have fallen far below such a standard. Cartography and statistics form the sum and substance of these treatises. Maps constitute an essential feature of geography, but are commonly read with less intelligence than the working drawings of an engineer or architect. Lists of cities with their populations, and the names of rivers, bays, mountains and islands are of great value in the way of information, but they are of secondary importance. It concerns the student of geography less to know that New York is a city of three millions and a half of inhabitants and the greatest seaport of America than to discover the causes which have led to such growth and development. The physical or social reasons for the fixing of political boundaries are of greater interest than the mere location of or changes in the boundaries themselves. Happily a change for the better may be observed. The recognition some years ago of the scientific and practical value of geography by German scholars, and the systematic work done by them have already borne fruit. Departments of geography have been established in universities and higher institutions of learning. Geographical societies have been organized in all the leading countries of the world, and a broader interest in the subject has been aroused.

Historical.— When Columbus (q.v.) made his first voyage of discovery, popular belief maintained that the earth was flat, though the scholars of the time recognized its spherical form. The first people to add to a knowledge of distant lands were the Phœnicians. They had founded colonies as early as 1200 B.C., and exerted much influence upon the progress of civilization. Herodotus, the father of history and geography, and himself a great traveler, records a Phœnician expedition in the 7th century B.C., which, staring from the Red Sea, returned by way of the Pillars of Hercules and the Mediterranean, having circumnavigated Africa. While the story has been doubted, the incidents of the narrative give it much color of probability. Herodotus leaves an account of the conception of the earth's extent in the 4th century B.C. The scanty knowledge of the time comprised the coast regions of the Mediterranean Sea extending vaguely to the north and south, with the Atlantic Ocean and the Persian empire constituting the western and eastern boundaries. Strabo's voluminous work on geography, at the dawn of the Christian era, itself a valuable treatise, is of special importance in affording a glimpse of the efforts of earlier geographers, whose books are lost. Eratosthenes, the most remarkable of these scholars, made wonderful advances in mathematics and astronomy. He measured the obliquity of the ecliptic, described the earth as a sphere revolving on its own axis, and constructed maps with parallels of latitude and longitude. Beyond influencing the belief of a few learned contemporaries, his work was practically unavailing. Ptolemy, who lived in the 2d century A.D., was the supreme authority in astronomy and geography, not only in his own time, but during the Middle Ages. In accordance with his system, which was really a compilation of the views of earlier writers, the centre of the universe was the earth, around which the various heavenly bodies revolved. The travels of Marco Polo in the 14th century and the introduction of the mariners' compass were instrumental in changing the whole history of the human race. See EXPLORATION.

Though the knowledge of our world progressed by leaps and bounds, it is interesting to note what a large proportion of that knowledge has been the result of modern investigation. Explorers on the sea had by the end of the 18th century become familiar with the range of the ocean, the outline of the continents and many islands, but at the beginning of the 19th century four fifths of the land area were unknown. Africa, with the exception of a narrow rim of coast, was indeed a "Dark Continent." Little had been added to our knowledge of Asia since the days of Marco Polo. West of the Mississippi, North America was a *terra incognita*, and the existence of the Rocky Mountains was not suspected. Even the coast of Australia was not completely traced, and nothing had been learned of its interior. South America, which was better known than any continent except Europe, is now the least explored of all the large land masses. With the advent of the 20th century scarcely one eleventh of the land surface remains unexplored. Excepting a few interior tracts, the only portions yet unconquered lie around the North and South Poles, and these are rapidly yielding to persistent effort.

While the unity of geography should never be overlooked, the subject is commonly divided into different branches, the chief of which are mathematical, physical, and political geography.

Mathematical Geography considers the earth as a globe, with its motions and their effects, and teaches the methods of representing the whole or portions of the earth's surface on globes or maps. Observation and careful measurements have proved the earth to be spheroidal in shape. As it is flattened at the poles, it is not a perfect sphere, nor even a perfect ellipsoid, but a ball with slight irregularities of surface. Its longest diameter is 7,926.6 miles, and its shortest 7,899.6 miles. The circumference is approximately 24,000 miles.

The axis of rotation of the earth is its shortest diameter. The ends of the axis point to opposite parts of the sky, and these, called the poles of the heavens, seem to stand still while the rotation of the earth causes an apparent revolution of the sky from east to west. The whole system of determining position and direction is established by the earth's rotation. The great circle midway between the poles is the equator. Great circles extending north and south through the poles are meridian circles. Distance from the equator toward either pole is called latitude, and is measured along a meridian. Zero is at the equator, and the quarter circle north or south is divided into 90°. Small circles parallel with the equator are parallels of latitude. The equator and parallels are continually moving from west to east, and the meridians, which cross them at right angles, are carried in succession directly beneath the sun. All points on any meridian turn around the axis at the same rate, but the actual distance traversed varies from nothing at the poles to more than 1,000 miles per hour at the equator. The uniform rotation of the earth provides a

means of measuring time. The sun crosses the meridian or midday line of any place midway between the hours of rising and setting, and the interval between 2 successive noons is called a day, which is divided into 24 equal parts or hours. It is always noon on some meridian, but never on more than one at the same instant. As a complete rotation through 360° occupies 24 hours, meridians 15° apart vary one hour in local time. A person traveling toward the east completely around the world gains a day, but if he make the same journey in a westerly direction he loses a day. Distance east or west is measured on the equator or a parallel, and is called longitude. Some prime meridian, usually that of Greenwich, is the zero, and measurements are made 180° east and west. The length of a degree of latitude is a little more than 69 miles, but as the meridians converge toward the poles, degrees of longitude diminish in length as the distance from the equator increases. If the latitude and longitude are unknown, the former is determined by observing the altitude of the pole of the heavens, while the latter is obtained by comparing, with the aid of a chronometer, the exact moment at which the sun crosses the meridian with the local time of the prime meridian at the same instant. Tables, showing the relative positions of heavenly bodies for each day in the year, are calculated in advance and enable captains of vessels to find their position at sea. See EARTH.

The imaginary network of meridians and parallels can be actually drawn upon a globe. The outline of the continents and the location of places may thus be depicted with great accuracy. A map is much more convenient than a globe, but, as the surface of a sphere cannot be spread out flat, no map is ever absolutely correct. Various projections are employed to modify the distortion. Mercator's projection, and others similar in plan, are modifications of the result obtained by drawing lines from the centre of a sphere through the parallels and meridians to the surface of a cylinder touching the sphere at the equator. This style of projection is employed for navigators' charts, for while areas are distorted, a straight line drawn between any two points correctly represents direction. Several hemispherical projections upon a flat background are used. These, though approximately preserving dimensions, distort directions. For limited areas the conical projection is of value. The meridians and parallels appear as they would if traced on a transparent cone placed on the globe.

Physical Geography deals with the earth in its relation to nature. The surface is irregular, the hollows being filled with water, and the projecting parts forming the dry land. It is surrounded by a gaseous envelope. The solid portion is often called the geosphere or lithosphere; the liquid layer, the hydrosphere; and the outer mantle, the atmosphere. See AIR; ATMOSPHERE; VAPOR.

The earth is believed to be a cooling and contracting body. With a reduction in size the outer crust becomes wrinkled. The crests of these wrinkles protrude above the water, which fills the troughs. Though many changes have affected these ridges and furrows, the general arrangement of the elevated and depressed portions of the earth is believed to have been nearly permanent. Without altering the relative positions of the exposed land masses and the oceanic basins, a comparatively slight increase in the depth of the latter would cause more land to be uncovered. Or were the bed of the ocean to be raised slightly, the sea would flow over the coast regions and accessible low-lying valleys. Were the solid crust uniformly smooth, it would be completely drowned by a continuous sea about two miles in depth.

By the present arrangement, the land area constitutes 28 per cent of the surface. The ocean covers about 72 per cent, but by evaporation and condensation, some of the water is distributed over the continents to be retained in lakes or returned to the sea by rivers. Though special names are given to different portions of the ocean, it is a continuous body of water.

The surface temperature of the ocean varies with the latitude. Ice floes and icebergs form in the polar seas, while an average temperature of 80° is maintained in the tropical ocean. The daily or seasonal range is not great in any latitude. Even in the tropics heat does not extend far below the surface, and the ocean as a whole is a mass of cold water.

The amount of dissolved salts in sea water averages 3.5 per cent. The salinity is not uniform, as portions are regularly freshened. These are chiefly the belts of equatorial rains, the regions affected by the melting ice of the polar seas, and those near coasts receiving the drainage of large land areas. As heat expands sea water, thus reducing its density, it generally happens that the surface water is salter than the colder layers below. The distribution of heat and the modification of climate effected by ocean currents is of vast importance. Nearly half the sun's heat in the Torrid Zone is carried to higher latitudes. The Arctic regions receive more heat from the Gulf Stream than they do directly from the sun. The western coast of Europe from the North Cape to Gibraltar has a climate much warmer than that of the opposite coast of North America, and this work of the Gulf Stream is in a measure duplicated on the western coast of North America by the Japan current. Cold currents from the southern ocean soften the climate of the western tropical coasts of Africa and South America. If the water completely covered the earth, a double wave caused by the attraction of the moon would, on account of the earth's rotation, travel around the globe every day. This ideal arrangement of tides is not realized except in the southern ocean, and, with a general movement to the west, the tidal wave is deflected northward in the other oceans.

In determining the height of mountains or any part of the land surface, it is necessary to have some common level as a basis of comparison. For this purpose the surface of the sea has been chosen, but on account of the many movements to which the ocean is subjected and because of the attraction exerted by elevated land masses, its surface is not level, and all comparative heights are of doubtful value. Efforts have been made to determine the mean level of the whole surface. While much has yet to be accomplished in securing the requisite data, it has been quite clearly shown that such a line lies about 10,000 feet below present sea-level. The abysmal area below this line is of equal extent with the area above it. As the exposed continental area occupies 28 per cent of

the earth's surface, it follows that 22 per cent is covered by water less than 10,000 feet in depth. Quite a large part of this region slopes gently away from the coast line to a depth of 100 fathoms, forming the continental shelf. The area of this submerged shelf is very nearly the same as that of the low costal plains of which it is a continuation. Were the level of the sea to be reduced 600 feet, 10,000,000 square miles would be added to the land area, and the present exposed surface would sustain a loss somewhat greater were the sea to rise an equal amount. The proportion of land is much greater in the northern than in the southern hemisphere, and the large land masses have their greatest width in the north.

The destructive agencies are so active that in a short time all the land would disappear and be distributed over the bed of the ocean, were it not for the upheavals due to the contraction of the crust. From causes, concerning which all geologists do not agree, lines of weakness are developed, and portions of the crust are forced up into mountain ranges or broad plateaus, while other adjacent portions are depressed. The outer rocks or those forming the slopes of a young mountain range are composed of the sediment of older rocks. They are the result of processes of destruction and reconstruction, which are to be at once renewed. For no sooner are new areas exposed than the sun either by direct heat, or through the agency of wind, frost, rain, or running water, proceeds to carve the surface into new forms, carrying away the waste to cover the rocks with soil for the support of vegetation or to fill up the hollows of the sea. Rain not only attacks the rocks by force of impact and solution, but by moving broken fragments from higher to lower levels it uses them as cutting tools. The surface water and that flowing from springs form little streams, which uniting produce rivers. In its upper course, which is the steepest, the work of a stream is purely destructive. It is cutting a gorge or valley in the high land. As the slope becomes more gradual, it is alternately depositing its load of stones and gravel or sweeping them away to some lower point. In its final stretch through a nearly level area it is building up an alluvial plain. Deltas and many interior valleys, like that of the Mississippi, are thus formed. Rivers carry away immense quantities of solid material, and are continually cutting down or extending their basins. The tendency of river work is to reduce the land to a dead level, and a subdued surface is usually an indication of old age.

Relief, or the vertical aspect of a land area, is the result of the forces of upheaval and erosion, which are continually at work. The arrangement of mountains, plateaus and valleys varies in the different continents, and upon the arrangement, climate, the possibilities of development, and the history of a country largely depend. The principal mountain ranges are, however, so disposed that all of the large drainage areas are tributary to the Atlantic Ocean or its arms. Asia, the largest continent, has the greatest average elevation and the highest point of land.

The many changes in the inorganic world profoundly affect the organic world and the distribution of life. In turn, the very processes of nature are largely influenced by living organisms. The spread of any species, animal or vegetable, is promoted or retarded by such geographical features as oceans, mountains, plains, deserts, and climate, but marine animals, by withdrawing dissolved carbonate of lime from the sea water, have constructed mountains of limestone, and vegetation retards the work of denudation, regulates rainfall and modifies the rate of evaporation. Plants alone are able to construct organic from inorganic material, and animal life is dependent directly or indirectly upon plants for food.

All plants and animals are adapted to certain environments and could not live if the essential conditions were changed, but every form of life does not of necessity reach every region suited to it. Natives of one country when carried to another frequently develop with amazing rapidity, even to the extent of crowding out indigenous species. In the tropics, the forests contain a variety of forms, and the large animals live singly or in families. In the temperate zones many plants and animals for mutual protection are gregarious. Forests often contain only one kind of tree, and the variety is never great. Grasses do not grow singly as in hot climates, but form a sod. Animals move in herds and fish in shoals.

Natural distribution has been greatly modified by man. In some regions the large land animals have been exterminated, and vast forest tracts have been removed. Domestic animals and cultivated plants have replaced the native species. Man alone of living creatures is able to rise superior to his environment, to conquer and control adverse geographical conditions. This faculty is acquired, and is the result of long development. Primitive man was undoubtedly as helpless as other animals. The same sort of barriers that retard the migration of species, have also affected the growth of nations, and no thorough conception of history, which is a record of man's development, can overlook the fundamental importance of geography. It was not until the barriers were broken down and until isolation gave way to intercourse with other peoples that civilization made safe and permanent advances.

Political Geography deals merely with the distribution of the human race in different communities, but an intelligent study of the boundaries of states involves an acquaintance with natural geographical conditions and the history of the inhabitants. It has been proposed to divide history into three periods. The first, known as the Fluvial, includes the growth of nations developing in fertile river deltas, with such scanty means of intercourse as the streams afforded. The Mesopotamian nations of Assyria and Babylon, the Egyptians, and the Hindus, are well-known examples. As the sailor became more venturesome, and skirted the shores of large inland seas, the Mediterranean period succeeded the Fluvial. Columbus and Vasco da Gama inaugurated the last, or the Oceanic period. Such a view is at least not inappropriate in tracing the development of commerce.

Commercial Geography is the most practical branch of the subject. It means a knowledge of the distribution of the world's products, of existing demands for these commodities, and satisfactory means of transportation and exchange. The Phœnicians were the first great traders. Their horizon was prac-

tically limited by the shores of the Mediterranean, although they sailed beyond its confines, and many of the goods with which their ships were laden were brought to Syria by caravans. The Phœnicians were succeeded by the Carthaginians and the Greeks, but the typical merchants of the Mediterranean class were the Venetians. Their supremacy in the world's commerce was unquestioned until, at the close of the 15th century, the Atlantic succeeded the Mediterranean as the highway of trade. The centre of the world's commerce then passed in succession from Portugal to Spain, and then on to Holland, the Hanseatic towns and London. To-day commerce is not a monopoly, but is world-wide. In volume of trade the United States is surpassed by no other nation, but competition is keen, and the successful merchant of the future must be well versed in that knowledge of which geography forms the basis.

The growth of commerce has been in direct ratio to the extent and rapidity of geographical discovery. Some of the conditions, which are favorable or unfavorable to trade, are quite obvious. An indented continental outline and navigable rivers reaching the interior are most desirable features. In these respects, Europe and North America are fortunate. Asia also is penetrated by arms of the sea, but her largest rivers, like the northern streams of North America, are practically useless, because they are tributary to an inhospitable frozen sea. Africa has no breaks in its contour, and its rivers reach the sea by dropping from a plateau. Though lying next to Europe, it baffled both the curiosity and the greed of her adventurers until the latter half of the 19th century. South America is not wanting in inlets, and her river systems are remarkable, yet very little is known of the interior. It becomes evident that latitude is an important factor in the case of both Africa and South America. The torrid heat, the burning desert, and the deadly fever were obstacles which the African explorer dreaded. The stagnation of South America is also explained when its tropical position is considered. Aside from topography and climate, the character of the inhabitants has much to do with the success of commercial intercourse.

Commerce has expanded because man has been able to meet and to overcome natural obstacles. He has to a great extent eliminated time and distance, by cutting canals through isthmuses, by connecting the shores of the oceans by continental railroads, by the substitution of steam vessels for those propelled by the wind, and by girdling the globe with the telegraph. He has modified climate both as to rainfall and healthfulness by the planting or removal of trees, and by drainage of the ground. By irrigation, he has made the arid waste productive and fruitful. At the beginning of the 19th century, the merchant was obliged to visit the region in which he desired to purchase his commodities, and to carry with him the money for payment. Now, by the aid of a cosmopolitan system of credit, he may within a few hours buy in one part of the globe and sell in another without leaving his office.

F. B. Greene, A.M.,
Secretary, Geographical Society of Philadelphia.

Geolog'ical Society of America, an association of geologists organized in 1888. It was the outgrowth of the geological section of the American Association for the Advancement of Science. The society has a restricted membership of 300. A quarterly bulletin is issued under its auspices.

Geological Survey, United States, a bureau of the Interior Deparment created for the purpose of preparing a map of the United States, classifying the public lands, examining the geological structure, mineral resources, and the products of the country. To these duties have since been added those of investigating the extent to which the arid lands of the West can be redeemed by irrigation, segregating the irrigable from the non-irrigable lands, and the selection of sites for reservoirs and canals for the purposes of irrigation. The maps made by the Geological Survey are all on a large scale, and have a degree of accuracy and a minuteness in detail incomparably greater than ordinary maps. The smallest scale is 1-250,000, or about 4 miles to the inch, and this scale has been employed for regions of the West which are thinly settled, and where the topography is mountainous. But it has been superseded by scales of 2 miles and 1 mile to the inch, the latter for populous regions with slightly or moderately diversified topography, like Massachusetts and New Jersey. The maps are engraved on sheets which, with the 4-mile scale, embrace 1° of latitude and 1° of longitude. The 2-mile maps embrace tracts of half the above linear or one fourth the areal dimensions; the 1-mile maps embrace one fourth of the above linear and one sixteenth the areal dimensions. The topography is represented by «contours» or «grade curves»; that is, by lines of equal altitude above the sea. The contour intervals are uniform for each sheet, but vary in different sheets according to the character of the country. In some tracts the contour intervals represent a difference of elevation of 200 feet, these being in very mountainous countries, while in flat countries and on large-scale sheets they may be as small as 20 feet. The general construction and methods of all maps are, however, the same.

There are three principal branches of the geological survey: (1) Geology proper; (2) topography; (3) irrigation surveys. The geological branch investigates the stratigraphy, the geological structure and history, the lithology, mineralogy, and palæontology, the ores and mines, and in general the natural economics, resources, and physical geography of the country. The topographic branch prepares the maps; the irrigation branch investigates the possibilities of irrigation and selects the irrigable lands and sites available for reservoirs and canals. The work of the topographic branch is the basis of the work of the other two, and all the results of the latter are projected on the maps. The publications of the survey are: (1) the annual report of the director, which, besides the administrative report, contains memoirs on geologic subjects by members of the survey, and is distributed according to the regulations of the Interior Department; (2) monographs on the leading subjects of special investigation by the geologists; (3) bulletins on more limited special subjects of research; (4) an annual volume of mineral statistics. The last three are distributed gratuitously only to designated libraries and to learned

corporate societies, which send their own publications in exchange. Otherwise they are sold by the director and the money deposited in the treasury. See GEOLOGY; IRRIGATION; TOPOGRAPHY.

Geology is the science of the Earth's history. In common with myths of creation that appear in the folk-lore and religions of all peoples, geology recognizes the essential fact of changes which make up a history; but it differs from the myths in being well-ordered knowledge based on observation, in interpreting natural phenomena according to the laws of the material world, and in seeking causes among the forces of the physical universe. Guesses at the beginning or the end are not part of the science, which deals only with those eras that are recorded in the rocks.

Geology is a very comprehensive science, embracing some knowledge from each of the chief natural sciences. The Earth, a planet, may be studied as a member of the solar system and in comparison with stars; and in so far geology joins astronomy. The Earth is composed of elements, associating and combining according to the laws governing physical and chemical activity; thus geology includes physics and chemistry as applied to rocks, seas, and air. The Earth has been and is the home of multitudes of living beings, whose development has been conditioned by her changes and is part of her history; organic evolution, as studied through comparative botany and zoology, is, therefore, part of geology. A great geologist has defined geology as astronomy, physics, chemistry, and biology applied to the Earth.

Aims of Geology.— The aims of geologic research may be classed as three: (1) To discover the principles, the forces, and the processes of the Earth's development; (2) to trace the history of the physical world and of its organic inhabitants; (3) to advance the exploitation of natural resources for the benefit of mankind. Those views which are now current and which represent the present advancement of the science are briefly suggested in the following paragraphs, but for a more complete treatment the reader must be referred to the books and articles mentioned in the bibliography.

A Fundamental Principle.— The causes which are now effective in producing changes in the Earth have been in operation throughout all known eras of her history, and the past is to be interpreted in the light of the present. This general principle applies to all departments of the science, and is the foundation upon which all knowledge of the past is built up. If the substance of the Earth ever formed part of a nebula, it condensed according to causes now operating in nebulæ. If it was once a molten globe, it cooled and solidified as a molten globe now would. Upon the cool Earth, rains have ever fallen, streams have always flowed, seas have been gathered into basins about lands; and the processes now active on the continents, in the oceans, and within the rock mass have been active continuously, but in greater or less degree.

The intensity of geologic processes is unequal at the present time in different parts of the world, and during past eras has varied from age to age for each and every zone. The most familiar process, that of erosion, which comprises all the chemical and physical effects of the atmosphere upon land surfaces, produces very different results in lowlands and in highlands, in humid regions and in deserts, in the tropics and beneath the pole star; and during the past it has varied in the nature and intensity of its activity, as the governing conditions were more or less favorable. In these respects erosion may be considered as an illustration of the variability of other processes, all acting under immutable laws.

Geologic Forces.— The natural forces which are involved in geologic processes are: (1) Radiant energy of the sun, namely, light and external heat; (2) gravitation, both terrestrial and general; (3) chemical energy; and (4) the vital force.

Summary of Effects.— It may promote a clearer understanding of the operation of these forces to give some illustrations of their effects, before making a fuller statement of the processes of geologic change. Sunlight and heat directly act on rocks in deserts, where they are unhindered by vegetation and moisture. The brilliant glowing days and the radiantly clear nights result in changes of temperature which cause rocks to expand and contract and in consequence to crumble. The sands of Sahara are in part grains thus broken from granite. Less direct, but more widely effective, is the action of the sun through the agencies of the atmosphere, the winds, snows, frost, rains, and running streams, all of which are started and kept in motion by the sun. In life also the sun's energy is manifest.

Gravitation, as it is expressed in the force by which all things are attracted toward the Earth's centre, is familiar to us. Winds are influenced by it, rains obey it, and streams flow in accordance with the laws of its attraction. Thus gravitation and sun force cooperate in the movements of the atmosphere. Gravitation holds the oceans in their beds and the firm Earth to its form. It is the cause of pressure within the Earth, and immediately or remotely of the Earth's internal heat. The manifestations of pressure and heat are therefore attributable to it, and these include a great range of phenomena.

Chemical energy, which controls combinations of elements, and of which we avail ourselves in manifold ways, governs the constitution of minerals, the composition of the air, and that of the sea. It is effective when rocks, like an iron bar, rust at the surface of the Earth, as it is also when they change in structure and recrystallize within the Earth. All ores are chemical compounds and owe their concentration in valuable ore bodies to chemical reactions.

The vital force has animated myriads of creatures, which have built their shells or skeletons, each according to his kind, and left them as grains in great rock masses. Strata many hundreds of feet thick and many thousands of square miles in extent are composed of such remains, which thus form stupendous monuments to the activity of the vital force. But this is not all. Living creatures are liable to change according to environment, and obey a great law of adaptation and progress, the law of evolution. They have, therefore, changed as the conditions of life have changed; they have

evolved from lowest to higher forms, and are evolving. Finding their remains in strata according to a definite sequence, we are able for that place to trace the progress of evolution; and comparing stages of evolution as discovered in strata in different provinces or continents, we can ascertain in how far the succession of events affecting life was the same or was different, in Europe, for example, and America. Though differences are discovered, likenesses are surprisingly general and close, and it is believed that the parallel developments of life in different continents have occurred nearly simultaneously, age for age. Thus the time scale of geologic history is based on the evolution of living forms through vital force.

Geologic Processes.— The forces which have been described are active, and long have been, in three realms — in the atmosphere, in the seas, and in the solid rocks. They interact in each realm, and in each give rise to a group of characteristic phenomena. Thus there is an interaction or process which goes on in and beneath the atmosphere, where air and moisture affect the surface of the land, and which is called *erosion.* A second process is active in lakes and seas, in and beneath the waters; it is called *sedimentation.* And a third is that which is manifested in the movement and distortion of rock masses, and which is known as *deformation.*

Erosion.— The process of erosion may be briefly described as the process of land sculpture, the effects being observed in the forms of plateaus, mountains, hills, slopes, valleys, and plains. The forces involved have already been stated as sunlight, sunheat, chemical energy, and gravitation. The process involves several distinct sub-processes, which are broadly classified under the four heads of weathering, transportation, corrasion, and aggradation. The active agents by which the forces are applied are, primarily, the air and water in its various forms, and, secondarily, vegetation and other organisms, with their products of decay. The materials affected are rocks, and these, being aggregates of chemical compounds more or less compactly bound together, differ greatly in the degree of resistance which they offer to the same activities. Limestone, for example, being readily soluble in water containing carbonic acid, occasions valleys in a region of vegetation and moist climate, whereas sandstone maintains ridges. In an arid district these relations may be reversed.

Taking up the sub-processes of erosion we may briefly describe them, considering that of weathering first. Changes of temperature, such as ensue when brilliant sunlight is followed by clear nights, occasion sufficient change of volume in rocks to cause them to crack and shatter, as has been stated. The expansion of water in freezing widens crevices. Chemical changes in rocks are brought about at and near the surface of the ground, chiefly through water, the common solvent, which becomes particularly efficient when it contains carbonic acid or other organic acids resulting from decay. With many minerals water forms a chemical combination by which they become hydrated, as it is called, and their volume is thereby increased. Feldspar, a constituent of many crystalline rocks, is especially liable to this change, and the force of expansion due to the chemical combination is sufficient to dislocate and loosen the bonds that hold the grains together. Consequently, such rocks crumble anad form a loosened, porous covering to the sounder rock remaining beneath. This porous material, being hydrated, is more readily attacked by carbonic acid; and soluble carbonates of iron, lime, magnesia, soda, potash, etc., are formed and taken into solution. Certain insoluble constituents (chiefly quartz, silicate of alumina, and oxide of iron), remain mixed in various proportions, and constitute what are commonly known as sand, loam, and clay. The rocks which are not usually recognized as crystalline, such as sandstone, mud rocks or shales, and limestones, are broken down, in part mechanically, through heat and frost, and in part chemically. Limestone, as already stated, is peculiarly liable to solution. Those silicious rocks known as quartz, sandstone, and quartzite are especially resistant, and where they occur in masses always maintain hills, which stand higher than the worn surface of other rocks, or where they have become broken may be carried to great distances and form beds of white and brown pebbles, so commonly found.

The sub-process *transportation* is effective in distributing the products of weathering. Gravitation is the essential force, and the mantle of soil which accumulates through the mechanical and chemical activities that have been enumerated, is moved ever downward in one way or another. On steep slopes and cliffs gravity acts simply upon any loosened block, whose diminishing support finally fails and allows it to fall. Of soil resting even on gentle slopes, a mass softened by water may creep downward, or, loosened, move in such volume and so far that we recognize it as a landslide. These, however, are minor effects. In arid regions wind, the chief carrier, moves the sands of the desert, whose billows have been likened to the sea. Greatly predominant, however, the world over, is the work of running water, which from the tiny rivulet that gathers from the rain falling on a field to the great floods of the Mississippi or Ganges, is always laden with a greater or less burden of earth held in suspension, or with substances taken from the rocks by solution. The effects of this almost universal activity are incredible. It must be credited with having changed the face of the Earth again and again in the long lapse of geologic ages, and with having swept away the greatest mountain ranges and reduced continents to flat plains.

Corrasion, the third sub-process, is the wearing of stream channels. Waters gathering on a soil-covered slope wash with them particles of sand and clay. Where they fall over any inequality, they deepen the hollow beneath it, and undermine their tiny banks. Gathering volume and velocity, they acquire force to work more vigorously, and if not checked develop deep gullies. The stream at any place in its course where it has sufficient velocity, sweeps along whatever sand and clay has been carried thus far, and scours the hard rock bottom. The effect is that of a file, and the channel is deepened. If the resistant rock is a rim underlain by softer beds, the waters dig out the channel below and form a gorge, at whose upper end is a cascade, perhaps a Niagara. They may completely file through or undermine the hard rock, and thus in time lower the level of the channel to a position determined temporarily by some

rock rim farther down the stream, and ultimately by the level of the sea. There is no limit to this activity of the stream short of that slope from sea-level on which the waters can no longer keep the channel clear of sediment.

The cut which any stream makes is narrow, and it may become a deep canyon without growing very wide; but the rocks differ very much in their capacity to maintain steep cliffs or slopes; none of them endure forever. Wherever cliff faces stand boldly up, atmospheric activities loosen and undermine each jutting point, and as each falls, exposing another, the cliff recedes. When the retreating cliff becomes a slope, branching gullies develop and grow like twigs at their heads, since not only the main stream is engaged in sinking its channel, but every tributary, including the smallest rivulets, is doing the same according to its power. Growing, branching, multiplying, they become widely effective, and in time attack the entire land surface, however extensive. Throughout the early stages of this process, while channels are narrow, slopes are steep and the surfaces of highlands are broad; the landscape is then said to be young. When the streams have carried on their work so far that valleys are wide, slopes gentle, and the highlands but narrow ridges, it is said that the topography has become mature. And when, the process continuing, the highlands lessen in altitude until they become eminences scarcely rising above the valley plains, the phase is called aged.

Aggradation is a word which may be translated as valley filling. It applies to that sub-process of erosion whose effects are seen in bottom lands and flood plains along rivers. The sand and clay which are transported by rapid streams are dropped where the current slackens, it may be at a distance from the sea and high above it, or along the lower reaches of the river. The one is but an interruption in the journey of the sediment from the heights; the latter is a more prolonged but not necessarily a final stop. The winding course of a mud-loaded stream, like that of the lower Mississippi, is caused by the shoals which form in eddies and, diverting the current, cause it to cut away the opposite bank. Thus shifting, a channel wanders widely and widens the valley. By deposits made during moderately high water a heavily loaded river also builds up its banks till they stand above the adjacent flood plain, and in time of floods it may break through them and spread a fresh deposit over great stretches of fertile plain. Every spring has its story of broken levees along the Mississippi, and that river is not peculiar in this respect. The ultimate character of all valleys, if development goes on unhindered, is that of flood plains as extensive as are the lands, and valleys thus become stored with alluvium, which in course of geologic changes goes to form sedimentary rocks beneath the sea.

A phase of erosion which is not included in the above statement is that carried on by the sea along the shores where it attacks the land. The power of the sea is derived chiefly from the winds, and depends upon their prevailing direction and the distance throughout which they blow across its surface. for the winds raise the waves, which gather force as the effect is continued over wide stretches, and the dash of the waves on the shore is the effective eroding activity. The land resists according to its altitude and the coherence of the rock masses, in some places developing bold headlands, and elsewhere becoming fringed by extensive beaches. The attack of the sea is delivered in a horizontal plane at and just below the water surface, and its effect, when sufficiently continued at one level, is to cut away whatever is higher, and to produce a bench, at the inner margin of which rises a cliff or slope. The material that is worn away is carried by undertow and shore currents and distributed along the coast in favorable locations to form beaches, and beneath the sea as widespread deposits. These phenomena belong to the process next to be described — that of sedimentation. The effects upon the land depend not only upon the resistance offered to the sea, but also upon the continuance of the process. If a shore has been newly established it follows all the sinuosities of the surface contour, retreating far landward in deep valleys, projecting far seaward about headlands and islands. But when the sea has cut and built at the same level during a long time, it may have carved away the headlands and extended beaches across the bays, and thus have straightened the shore line. There are, therefore, youthful shores and aged shores, as there are youthful canyons and aged valleys or plains.

Sedimentation.— Sedimentation may be described as that process which results in layers of sediment spread under water. In a special sense the name is applied to the process as carried on in lakes and seas, and to the strata which are thus produced, but in a more general sense it may include methods of deposition of material borne by streams, by ice, and by winds, and may thus cover a large part of the effects above included in the process of erosion. In this article it is used in the more special sense, sedimentary strata being considered to be lacustrine or marine in origin.

The sub-processes of sedimentation are *sorting*, *distribution*, and *deposition*. They are effected by moving waters, and thus depend upon the winds, tides, and ocean currents. All of these movements are directly or indirectly effects of gravitation, which is, therefore, the force to which sedimentation is ultimately due.

The work of waves in eroding the land was referred to in a previous paragraph. Through their constantly repeated attacks the pebbles and sands of beaches are abraded and reduced in size, and the finer is stirred up and carried away from the coarser. Every wave agitates and washes the material of a beach, and the successions of waves constitute a grinding and sorting mill of great efficiency. That material which may be moved by the onrush of the waves is swept along the beach in the direction of the prevailing winds or heaviest storms. That which is fine enough to be taken up by the undertow is carried down under the sea and distributed to a greater or less distance from the shore over the bottom. This work of the waves is exceptionally well illustrated in the beaches that fringe the Atlantic coast of the United States from Long Island to Florida, and in the mud which is deposited over the sea bottom even to a distance of 100 miles southeast of it; for this is a coast on which the waves break with great power, under the influence of the prevailing southeasterly winds, and which is composed of soft rocks that offer compara-

tively feeble resistance. It is therefore a coast of aged aspect, characterized by long, slender, wave-built beaches, and it contrasts strongly with the young rock-bound coast of Maine.

Where any great river, such as the Mississippi, brings its burden of sand and clay and delivers it to a sea in which the waves have but moderate power, as in the Gulf of Mexico, the river builds a delta, which interferes with the course of waves and currents, and is attacked by them. The form and extent of the delta are a result of the conflict between the river and the sea. The currents of the latter receive a considerable part of the river's burden directly, they may wear away other portions which the stream deposited when conditions favored, and they carry the material on to some place where it settles. Thus the South Atlantic ocean current circulates into and around the Gulf of Mexico from south to north and east, and receiving much clay and sand from the rivers whose mouths it passes, deposits it in eddies along the coast of Alabama and Florida; another part is swept on through the Straits of Florida, where the constricted Gulf stream flows swiftly, and is carried out to form a great bank where the Atlantic deepens north of the Bahama Islands.

Another kind of sediment, consisting chiefly of carbonate of lime, is derived from marine waters through chemical or organic agencies. Lime is known to be readily soluble when combined as a bicarbonate, and to be relatively insoluble as a monocarbonate. It enters into solution as the former, and is deposited in the form of the latter as a calcareous mud. The chemical and organic conditions which govern this process are not thoroughly understood. It is known that under some circumstances the change from bicarbonate to monocarbonate may occur through chemical agencies alone, and that in other cases it is carried out through the agency of organisms which live in the sea. Whatever the process, the result is the formation of vast accumulations of calcareous mud, which are chiefly of marine origin and distribution. The South Atlantic ocean current again affords an example; it sweeps through the Caribbean, bearing a multitude of marine organisms, many of which secrete calcareous parts from the water, and, dying, leave their shells to sink to the bottom. From lands composed largely of limestone flow hard waters that may throw down a limy mud, as is the case in the Everglades of Florida; and this also becomes sediment, which the current sweeps on with the organic remains and with the delta silts of the great rivers. The result is the deposit now forming in every deep hollow of the Caribbean, of the Gulf, and along the Atlantic slope of North America.

In the aspects of the coast of North and South America, from Newfoundland to Brazil, are comprised illustrations of most of the processes of marine sedimentation. There is the coast of Maine, through whose deep embayments sweep swift tidal currents, and onto whose shores play powerful waves, grinding and distributing chiefly coarse pebbles and sand. There is the coast of Long Island, New Jersey, and the Carolinas, whose beaches of clean, white, sorted sand stretch for miles, shutting in the estuaries into which the small rivers deliver their sediment, and enclosing the land within a wave-built barrier. Outside, beneath the shallow ocean, reaches a broad flat, which extends out to the margin of the continent, and on this is spread a small amount of mud, sorted from the sands brought by the undertow and distributed by tidal currents. In the Gulf of Mexico and the Caribbean are found, on a large scale, the conditions of delta building and of marine distribution of fine mechanical and organic sediments. Chiefly by processes such as these the sedimentary rocks have been formed throughout geologic ages.

Sedimentary deposits in estuaries and lakes are similar in many respects to those of seas, but as waves are less effective in these smaller water bodies, the sorting is less complete; shore currents are also less active, and materials are carried to less distance from their source; and that which is swept out from shore is usually fine silt only. Lake deposits are closely related to river deposits, especially in regions where torrential streams sweep detritus from hills far out onto plains and into the margins of lakes; and there are vast accumulations, as in the western United States, of which it is not yet surely known to what extent they are lacustrine or how much is fluviatile.

Chemical deposits may be formed in seas or lakes whenever peculiar conditions favor the separation of a substance held in solution. The commonly accepted view is that the substance must be present in amount sufficient to form a saturated solution, so that it is thrown down by evaporation. Such is the case with enclosed lakes having no outlet, like Great Salt Lake. But there are other circumstances, as when carbonate of lime is deposited from spring waters or from ocean waters without organic agency, where saturation is not the condition, yet the substance separates. Waters circulating in a nearly enclosed sea, like the Mediterranean, and subject, as it is, to excessive evaporation, may reach a condition of concentration short of saturation, yet adequate to cause precipitation; mechanical agitation, as that of the waves, may suffice to dissociate a loosely united compound like bicarbonate of lime, and thus to precipitate the monocarbonate (the exact chemical conditions are open to discussion and to experiment); but great bodies of chemical sediments exist, and among them carbonate of lime or limestone, sulphate of lime, or gypsum, and rock salt are the chief ones.

Deformation.— In geology the verb to deform is used in its exact sense — to change form — and not with the more commonly recognized meaning — to put out of shape or disfigure. The geologic process of deformation is therefore one of change of form, and may involve altering by pressure the shape of a stone, a bed or body of rock, a mountain mass, a continent, an ocean basin, or of the whole earth. It is a universal process, which has been effective throughout all time, though not always equally so. The earthquake and the volcano are effects of very local deformation, with intense activity and under special conditions; but the process is far more general than are earthquakes or volcanoes.

Terra firma — the firm earth — appears to be a rigid, unyielding sphere only because we are able to observe but small areas, and these for but brief times. The rounded form, flattened at the poles, is determined by the balance of

gravitation with the centrifugal force due to rotation on an axis. Were the attraction of gravitation more or less, the form would still be round, but would differ from the present; and so also, if the rate of rotation were to change so that a day were longer or shorter. This is so not because the earth is soft inside, but because it is so large a mass. The effect of mass may be seen in drops of mercury on a glass plate; tiny ones are nearly perfect spheres, larger ones are much flattened. If the earth were a solid sphere of granite, and could be supported at rest on a pedestal, it would flatten down to a thin sheet.

The rounded form of the whole earth being an effect of balancing forces, we may inquire what features of the surface are, similarly, effects of equilibrium. Are the ocean bottoms underlain by heavier material than that of the continents? And is that the reason why they have sunk so low in balance with the high-standing lands? Balance water and oil in a U-shaped glass tube, and this idea of the heavier ocean beds and lighter continents may become clearer. It is that which is now most commonly accepted as the probable explanation of the extensive inequalities of the earth's surface. Yet it has also been made evident that the earth is on the whole a rigid body; one line of reasoning being that if it were not there must be tides in the land as there are in the ocean, yet observations with delicate instruments have failed to detect land tides; another that earthquake shocks travel through the spheroid at a rate at which only a highly rigid substance could transmit them. This rigidity is conceived to be an effect of pressure which is due to weight of all the mass tending toward the centre. We have seen that the ocean basins are believed to crowd heavily downward, and to hold higher the lighter continents, so that the measure of the rigidity (which is called viscosity or resistance to change of form) is less than the weight of masses beneath ocean basins; but it is obvious that the viscosity is sufficient to sustain large high masses, probably those of mountains, not balanced by masses in lower positions. Time is an important element in these problems, the earth yielding to a sufficient pressure, as tar yields, slowly.

This sphere, whose mass is yielding, yet up to certain limits firm, is stored with energy in the form of internal heat, and is subjected to strains due to external attractions, to cooling, and to the gradual effects of erosion and sedimentation, removing mountains and other elevated masses from their positions on the continents to zones of deposit beneath the margins of the seas. The equilibrium is, therefore, liable to disturbance, which is expressed in movements of one sort or another. Whatever the nature of these movements, they all come within the process of deformation. Gravitation is the ultimate cause, but the immediate causes in any particular case may be obscure, and the search for them includes the most difficult problems of modern geology. Deformation is, therefore, better known by its effects, and through those it must be described.

Turning first to those evidences of movement within rock masses, the more obvious ones are found in forms which we know have been broken or stretched. Pebbles which have been cracked and separated while yet firmly embedded in the rock are not of uncommon occurrence, and there are those which have been pressed out, as one might a ball of wax, until they form long, thin, flattened lenses. Fossil shells whose original forms can be accurately determined are found similarly broken apart or stretched while yet embedded in the matrix of limestone or shale.

Again, rocks whose original character may have been massive or bedded are found to have recrystallized and to have assumed a lamellar structure, like that of a pack of cards. This occurs through a movement which is very like that of cards pressed between the palms and slipped one on the other. Such movements occur on a grand scale at depths beneath the surface of two miles or more and throughout masses of rock which are cubic miles in volume.

Again, it is known that many rocks, such as sandstones and limestones, were originally spread in flat sheets of great extent, as compared with their thickness, even though the latter may amount to several thousand feet. These sheets may be found to be flexed in a series of parallel folds, forming alternating troughs and arches, to be crumpled as though pressed from several directions at once, and to be dislocated and thrust over one part upon another. The compression involved in such folding amounts sometimes to a very notable shortening of an arc of the earth's crust. It is estimated, for example, that in eastern North America the space between the Cumberland plateau on the west and the Blue Ridge on the east, corresponding to the great Appalachian valley and the Alleghany ridges, has been shortened by at least 40 per cent, so that what was 100 miles across is now but 60. And, similarly, the zone of the Alps is estimated to have been shortened by compression by an amount of 74 miles.

Less obvious, but not less certainly effective on a grand scale, are the vertical movements by which ocean basins are deepened, while continents are left standing higher, and mountain systems are perhaps actually elevated in continental areas. The history of continents shows that they may not have maintained from time to time the same extent of land above sea-level, but on the contrary have been submerged now here, now there, now more, now less. These changes are attributed to deformation, in consequence of which ocean basins have varied in size, so that they at one time might contain all the waters, but at other times were relatively not so deep below the continents, which were in part overflowed. The general tendency of deformation is to lessen the earth's size, to shorten the radius, and the grand movements are movements of subsidence, but minor ones, such as the growth of mountain ranges, may be in part or whole movements of uplift, that is, lengthening of the radius.

The phenomena of erosion and sedimentation which have been described afford a means of tracing movements of subsidence and of relative uplift, not only in the present age, but through all the ages of which the sedimentary rocks yield records. As is explained more fully in a succeeding paragraph on the relations of geologic processes, erosion, the process of leveling down altitudes, must come to an end unless renewed by relative uplift. The successions of sedimentary rocks which may be observed in many parts of the world show that everywhere

erosion has been at times active, and at other times inactive for lack of the essential condition of elevated lands, and therefore that there have been similar alternations of epochs of relative uplift, which set in motion the activities of erosion, and epochs of constant level, which allowed that process to run down.

Thus from many points of view there are geological phenomena which show that the process of deformation has been of world-wide occurrence, and that it has been more or less effective from time to time during all recognized geologic ages.

Relations of the Geologic Processes.— We have enumerated three geologic processes — erosion, sedimentation, and deformation — in the order in which they are most easily recognized. Erosion goes on daily and before our eyes, and the phenomena which result from it are familiar. Sedimentation is so linked with erosion, and so closely related to the nature of our shores, that many of its phenomena are as easily recognized. Deformation alone is somewhat difficult to grasp; yet if we enumerate the processes in the order of their natural sequence, we must begin with deformation, for it is the initial process, from which the others result. Were the earth a perfectly smooth sphere the waters would be spread over it, erosion would fail for lack of land surface, and there would be no sediments available for the process of sedimentation. Only when, through deformation, the ocean basins should originate, could lands emerge. Even then, if those lands retained their smooth, flat form near sea-level, the opportunity of erosion would be very limited, and the amount of sediment supplied very scanty. Not until lands attained notable altitude above sea-level could the processes of weathering and of transportation deeply affect rock masses and convey any considerable volume of sediment to the sea. Only then could sedimentary rocks accumulate in large volume or of great extent.

Again, although there were elevated lands, the process of erosion tended constantly to reduce their altitude, and thus ever to lessen its own opportunity. If the altitude once established by deformation had not been renewed by subsidence and relative uplift, it must constantly decrease until the mountains had become worn to low hills, and in the lapse of ages to plains. This, indeed, has repeatedly occurred; the continents have seen one generation of mountains succeed another and each one waste away to lowlands. Deformation, therefore, is essential to the renewal of erosion.

And still again, if there be a basin occupied by a sea and so situated as to receive sediment from the land, that basin may in time be filled and its area added to the land, unless, through subsidence of the bottom, its depth be constantly increased. There was, for example, at one time, in the eastern United States, the basin of a shallow bay of the great interior sea which covered part of North America in the Devonian Age. In that shallow basin sediment 10,000 feet deep accumulated, and the ripple marks which occur on the surfaces of the rocks from the bottom to the top of that great thickness, show that it was ever near sea-level. That it could so gather, the bottom must have sunk about as fast as rivers from the adjacent land poured in the mud.

The three processes, therefore, are related to one another in a natural sequence, deformation being the initiative process, erosion the destructive process, and sedimentation the reconstructive process.

CLASSES OF ROCKS.

In General.— Although rocks are of many kinds, which may often be distinguished by the aid of special knowledge only, yet there are four great classes of rocks, which are easily recognized as a rule. Each class comprises those kinds which result from a distinct process, the classification being according to conditions of genesis. One class is due to deformation, one to erosion, and one to sedimentation; and the fourth may be the product of deformation alone or of deformation acting after either of the other two processes. The classes are: (1) igneous; (2) surficial; (3) sedimentary; and (4) metamorphic rocks. Rocks which are thus classified include not only the compact firm substances commonly called rocks, but also beds of ash, gravel, sand, or clay, of loose and incoherent texture. A rock, geologically speaking, is any aggregate of one or more mineral substances.

Igneous Rocks.— Igneous rocks are those whose constituent minerals crystallize from a highly heated condition. They were the earliest rocks, and have developed within the earth's mass at all times down to the present. Their initial condition is commonly described as molten, but only because that is the familiar condition of lavas, a well-known class of igneous rocks. When deeply buried within the earth, they are hot, but may be restrained by pressure from melting, water and gases are mingled with the other constituents, and the condition is probably one of potential fusion and solution. When fusion occurs, either through rise of temperature or lessening pressure, the molten mass behaves like a confined liquid, and pressing into any planes of weakness separates adjoining rock masses. Moving in the direction of least resistance, it rises toward the surface, which it may or may not reach. In the former case volcanic phenomena ensue, and the rocks are said to be extrusive. In the latter case the igneous mass cools and remains buried, and in course of time may be exposed through the process of erosion. It then exhibits the characteristic relations which it has assumed through being pressed in among masses of older rocks, and is called intrusive. The chemical and physical conditions of a magma, as the material of an igneous rock before crystallization is called, are not well understood. From one and the same magma different minerals crystallize out at different pressures and temperatures, and as pressure and temperature vary greatly in the ascent of the magma from deep within the earth to the surface, various kinds of igneous rocks may be formed at different stages of the journey. Thus it is possible to have a continuous series ranging from superficial extrusives down to deep-seated intrusives. The lavas and ash rocks may be taken as the types of the former, and granite as the type of the latter. Within the magma, prior to crystallization, chemical changes appear to go on, and it is observed that a sequence of eruptions in one and the same volcanic region, and presumably from the same magma, may consist of

successively varying rocks. One of the purposes of the study of igneous rocks through the methods of petrography, is to ascertain the phenomena of chemical and physical change which magmas undergo, and so to approach the problem of the chemistry and physics of the earth's interior.

Surficial Rocks.— Surficial rocks are products of erosion. Their constituents result from the decomposition of igneous or sedimentary rocks, and the surficial rock masses are formed in various ways, according to the agent by which they are transported to a place of deposit — wind, water, or ice. In composition they differ most markedly from the igneous rocks in that the elements which form soluble compounds, such as the alkaline earths, lime, magnesia, and iron, are removed in solution. Surficial rocks, therefore, consist to a large extent of the insoluble constituents, quartz, silicate of alumina, and oxide of iron. These occur in mixtures, which constitute gravel, sands, clays, and loams of various kinds.

Surficial rocks laid down by water are chiefly river deposits, and come under the general name of alluvium. They are familiar to every one in the bottom lands of streams large or small. Surficial rocks which are spread by wind are little known in districts of even moderate rainfall and vegetation, but in arid regions where dust, resulting from the disintegration of rocks through heating and chilling, is unprotected, they become important. They are exemplified by the sands of the desert. Again, upon the seashore, the effect of winds may be observed in sand dunes; and under special conditions (probably when through the action of glaciers great quantities of finely ground rock meal were provided where streams issued from the ice), the wind has spread over vast areas a sheet of fine dust, which forms the fertile soil of areas of the western plains of North America. A similar deposit of wide distribution occurs in the valleys of China. The peculiarly fine and homogeneous clay has been called loess, and there has been much discussion as to the relations which wind and water have borne in transporting it.

Surficial rocks laid down by ice are broadly classified into those which are produced by ice alone, those which are the product of ice and water together, and those which are produced by waters flowing from the ice. In general they are distinguished from sedimentary rocks chiefly by their heterogeneous composition, since through the action of glaciers in plowing and grinding the surfaces over which they move, rock fragments of various kinds and sizes become mixed, whereas the effect of water is to sort rock debris in distributing it.

Sedimentary Rocks.— Sedimentary rocks are those which are deposited beneath bodies of water which are either still or moving with moderate currents, such as affect lakes and seas. They are laid down in characteristically bedded deposits called strata, which may generally be distinguished from all other forms of rock masses, though sometimes the sediments of a lake or estuary so closely resemble those of a river that no distinction is possible. Along this line sedimentary and surficial rocks grade one into the other. The method of formation of sedimentary rocks has already been described in treating of the process of sedimentation, to which the reader is referred.

Metamorphic Rocks.— The word metamorphic means altered, and in its largest sense, when applied to rocks, would cover all those which are not in the original igneous condition. But it has come to have a narrower meaning, and usually designates a class derived from igneous or sedimentary rocks through the action of heat and moisture and pressure, usually at some depth beneath the earth's surface. That igneous masses which have cooled as intrusives beneath the surface should be subjected to such alteration is easily understood. Sedimentary rocks though formed at the surface may, through the processes of deformation and sedimentation, becomes so deeply buried as to be subject to the same influences. In any case, the process is one of recrystallization under special conditions of pressure, and often of slow movement, and the result is that the rock assumes a more or less crystalline texture, and frequently a thinly laminated structure described by the word schist. Metamorphic rocks are of various kinds, according to the material from which they are derived and according to the degree of metamorphism, which may range from a scarcely perceptible alteration of the original rock to such complete recomposition and rearrangement as to totally obscure the original character.

THE CRUST AND THE INTERIOR.

Some Physical Considerations.— The cooling globe, of which the interior is still very hot, was until recently universally considered to consist of a hard crust over a molten liquid interior, and this view still prevails generally among well-informed people. It is not, however, that which is held by students of the physics of the earth.

It is a general law that, within certain limits, a heated substance may be restrained from melting if confined under sufficient pressure. Pressures within the earth are an effect of gravitation, all substances pressing inward toward the centre, according to their weight. The results are given in the following table, and may be seen to be enormous.

VARIATION OF TERRESTRIAL DENSITY, GRAVITY, AND PRESSURE ACCORDING TO THE LAPLACIAN LAW.
[By R. S. Woodward, 1890.]

Depth in miles	Density	Acceleration of gravity	Pressure in atmosphere	Pressure in pounds per square inch
0	2.75	1.0000g	1	15
1	....	....	400	6,000
2	....	....	800	12,000
3	....	....	1,210	18,150
4	....	....	1,620	24,300
5	2.76	1.0006g	2,020	30,300
10	2.78	1.0012g	4,200	63,000
15	2.79	1.0018g	6,390	95,850
20	2.81	1.0024g	8,600	129,000
50	2.89	1.0060g	22,000	330,000
100	3.03	1.0116g	45,300	679,500
500	4.18	1.0379g	236,000	3,540,000
560	4.36	1.0389g	318,000	4,770,000
610	4.50	*a* 1.0392g	354,000	5,310,000
660	4.65	1.0389g	391,000	5,865,000
1,000	5.63	1.0225g	672,000	10,080,000
2,000	8.28	0.8312g	1,700,000	25,500,000
3,000	10.12	0.4567g	2,640,000	39,600,000
3,959	10.74	0.0000g	3,000,000	45,000,000

a This is the maximum value, and the corresponding depth, 610 miles, is the depth at which a given mass would have the greatest weight.

From these estimates it is inferred that the pressure within the earth is sufficient to restrain the mass as a whole from melting, and that a fluid globe within an external hard crust is physically impossible, in spite of the high temperature of the interior.

Under pressures which exceed their crushing strength, the condition of rocks must be one of greater density than at the surface. In fact, the earth having been measured and weighed, it is known that the density of the whole is approximately five and a half times that of water, or about twice that of the rocks occurring at the surface. Hence it is evident that the interior is much denser than the exterior, or, in other words, rocks within yield to the compression.

Direct evidence of the rigidity of the earth's mass has been found through studies of the tides and of earthquakes. Were the earth liquid it must be subject to tidal movements, as are the seas, but observations with very delicate instruments have failed to detect any such earth tides. On the other hand, earthquake shocks recorded by appropriate instruments are known to be transmitted directly through the sphere, as well as around it, and at a speed through the mass greater than that with which they pass around. This fact is taken by physicists as sufficient evidence of great elasticity of the earth's mass, which is consistent only with great rigidity. Thus along several lines of reasoning from the laws of physics, there is evidence that the earth is solid, not fluid, within; and this conclusion is sustained by the phenomena of deformation observed through the methods of geology. Movements of the earth's surface recorded in the development of continents, of lands, and of ocean basins have been so gradual that, considering the great mass of the globe, they are possible only on a rigid sphere. These considerations do not disregard the facts of igneous rocks and volcanic activity, which are, however, to be explained as intense and local results of special stresses set up through the process of deformation.

That portion of the earth's mass which is of most interest to man, and with which he is best acquainted, lies within the moderate depth of six miles from the surface. Here occur all the phenomena of mechanical and chemical change which result in mineral deposits of use and value. The relations of pressure to strength of material are of great importance, and through them the superficial crust is divided into three zones.

The uppermost is that in which all rocks are under such moderate pressures that when forced to move, in process of deformation, they break. Consequently in this uppermost zone, which has a depth of perhaps a mile, cracks and crevices are of general occurrence.

Beneath this superficial zone of fracture, but not distinctly divided from it, is another, in which weak rocks, such as the clay rocks, are constrained by pressure to maintain a coherent mass without open cracks, while other rocks of greater rigidity, such as quartzite, may still break apart. This is the zone of flow and fracture. Under such weight, beds of hard rock may be folded, as one may bend layers of wax, and folds may be pressed one over another till strata are overturned and the order of succession becomes inverted.

A third zone is known as the zone of flow. It lies at a depth of four miles and more below the surface, and is that in which no rock is capable of breaking, because the pressures exceed the crushing strength of any rock. When movement occurs, the masses change form as wax would. This zone is one in which and beneath which there can be no spaces not filled by rock materials, and beneath which, therefore, atmospheric waters cannot penetrate.

Beneath the zone of flow the materials are in that condition of heat and pressure which constitutes the state of potential fusion, referred to in describing igneous rocks; but the conditions so far exceed any which can be observed, that our apprehension of them must long remain in the state of hypothesis, rather than in that of knowledge.

The term crust may well be applied to the three zones of fracture, of flow and fracture, and of flow. The lower limit of the latter can not be defined, but within a thin film, at the most a score of miles deep, is the vast unknown interior.

Some Chemical Considerations.— Chemical reactions, involving exchanges of constituents between substances, are accompanied by changes of temperature and of volume. Burning is a reaction which gives off heat. When carbon is the substance burned, the product is carbon dioxide, CO_2; now we may heat CO_2 to a temperature at which it separates, or dissociates, into two gases (CO and O or carbon monoxide and oxygen), and in this change heat is absorbed; that is to say, in the presence of low temperature the reaction and the effects are the reverse of what they are in the presence of high temperature. If we consider the change of volume involved in different chemical reactions, we shall find those in which there is expansion, and others in which there is shrinkage. When lime is slaked, water combines with the lime and the combined volume is greater than that of the two before combination. The same reaction and result occur when moisture affects feldspar in granite, and combines with or hydrates it. The force of expansion is sufficient to burst the bonds which confine the feldspar crystal in the granite. If we heat the hydrated substance, we can drive off the water; and if the heating occurs under pressure the water is driven off at a lower temperature, because dehydration involves shrinkage, and therefore is promoted by pressure. These illustrations may serve to introduce the general law of chemical reactions as affected by heat and pressure, namely, that between two substances that reaction will tend to occur which meets least resistance or is most effectively aided by the environment.

If we consider the earth's crust as a scene of chemical changes we find that both temperature and pressure increase to a notable degree from the surface downward, and applying the above law we may expect that those reactions which involve liberation of heat and expansion of volume will tend to occur near the cool surface, whereas those resulting in absorption and contraction will be favored in the warmer zones below. The chief effects of weathering in the superficial zone of rocks are the substitution of water, oxygen, and carbonic acid for silica in combination with iron, lime, magnesia, and the

alkalies. Some insoluble oxides result, but silica and carbonates go into solution and pass downward into underlying permeable rocks, where they are deposited in great quantities. Beneath the zone of weathering there is thus a zone of cementation, in which the cavities in rocks become filled. If reactions take place the resulting minerals are those whose constitution is favored by high temperature and great pressure. Carbonates, which in combining expand and give off heat, are formed at less depths than silicates, which contract and absorb heat as they form. The zone of cementation grades downward into that of recrystallization, where chemical changes are brought about chiefly by movements within rock masses, and are altogether such as involve absorption of heat and produce heavy minerals.

If the physical and chemical conditions which have been separately suggested be associated as they are in the earth, we may state the effects in the following way:

and the frequency of overtakes. It may have been sufficient to result in general melting, but more likely was insufficient to raise the temperature of the mass to a high degree. This suggestion does not disregard the existing internal heat of the earth, but it has been shown by calculation that that temperature is adequately accounted for by gravitative concentration of the spheroid without external collision.

The earth, according to these considerations, entered upon its present phase of a solid globe with watery and airy envelopes, possibly from a previous condition characterized by somewhat higher temperature, possibly by aggregation of cold matter. When, if ever, a hot earth and a steaming atmosphere gave place to a cold earth with waters gathered in oceans (or when the growing planet had reached approximately its present mass), then began that chapter of history which may be recorded in existing rocks and which it is the object of geology to elucidate.

Zone	Depth	Physical conditions	Chemical conditions
Of fracture and weathering.	0 to 1 mile.	Many open spaces and relatively large crevices; comparatively free circulation of water.	Active oxidation, hydration, carbonation, and desilicification.
Of flow and fracture and cementation.	From near the surface to 4 miles.	Open spaces relatively small and growing smalier with greater depth, till only capillary openings remain.	Cementation by deposition of oxides, carbonates, sulphides, and silica.
Of flow and recrystallization.	3 to 6 miles.	Only capillary and subcapillary openings.	Alteration of rocks with development of heavy silicates.

GEOLOGIC HISTORY.

General Statement.— The astronomer, the geographer, and the biologist consider the earth's history from distinct points of view, the first regarding it as that of a planet, the second as that of oceans and continents, the third as that of organisms. The geologist's account comprises the later phases of astronomical history, includes all geographical changes, and furnishes the fundamental data for the understanding of organic evolution.

The astronomical history of the planet has since Kant and Laplace been based on the nebular hypothesis, according to which the solar system has resulted from the segregation of a homogeneous nebula, and the material of each planet has condensed from a gaseous condition to that which it now has. Intense heat must result from such condensation, and therefore the earth is thought to have cooled from a molten state. Mathematical tests recently appear to show that a homogeneous nebula could not condense to form a system in which the planetary masses should be distributed as they are in the solar system, and also that at the high temperature and great speed of rotation which are necessary to the hypothesis, the earth could not have held so light an element as hydrogen, which is an abundant constituent of terrestrial substances. An alternative hypothesis formulated by Chamberlain, suggests that small cold bodies, designated planetessimals, moving in a common orbit, have coalesced by overtake, rather than by opposed collision. The heat resulting from such a mode of aggregation may have been more or less, according to the size of the bodies

Permanency of Continents and Oceans.—The student of ancient terrestrial geography approaches his subject with a theory of permanent ocean basins and continents; the Indian, Atlantic, and Pacific, Eurasia, Africa, and the Americas are regarded as primeval features of the earth's surface. Yet it is known that every continental area has been submerged beneath marine waters more or less, again and again. The apparent contradiction of theory and knowledge lies in the fact that the words continent and ocean basin have a popular meaning and a technical one, which are not quite the same. In a popular sense the shore line divides the one from the other; in a technical sense a continent may (and now generally does) extend out under the shallow sea to a terraced slope that descends into the depths of the ocean basin proper. In other words, the ocean basins are too small at present to hold all the waters, which therefore overflow upon the margins of the continents. The basins, having been more or less capacious from age to age in the past, have now held, and again not held, all the waters, which accordingly have withdrawn from the lands, or have submerged them. But these changes have not affected the existence of the basins and continents as a whole.

Geologic Time.— The age of the Earth is inconceivable. This seems to be equally true whether we consider the eons which have elapsed since the planet became an individual in the solar system, or only the eras that have passed since it assumed its present physical characters as recorded in the rocks. That eminent physicist, Lord Kelvin, proceeding on the

assumption that the earth has cooled from a gaseous condition, has calculated that not more than 40,000,000 years, nor less than 20,000,000 years, have passed since condensation began. But we have already seen that the assumption is not surely correct, and geologists have uniformly contended that far more time was necessary for the events of which they observe the evidence. The estimates based on geological phenomena and comprising only the time covered by them, have rarely been less than 100,000,000 years, and larger ones are probably reasonable.

Before proceeding to state the divisions of time which geologists recognize, it is desirable to suggest the evidence upon which they base their distinctions. It is a simple principle that where sediments have been deposited, layer upon layer, the bottom strata are the oldest. And this principle underlies all determinations of relative geological age. It may be applied to any succession of rocks, however thick, which may be observed in a continuous exposure. In regions where the strata lie horizontally, such observations are limited to a few hundred feet, or at most to a few thousand. But strata are often observed to be tilted so that their edges are exposed in a horizontal surface, and there is then the possibility of examining the relations of strata many thousand feet thick.

A second principle rests upon the evidence of interruptions in the accumulation of sediments such as occur when the sea bottom is for a time elevated above the water and is exposed to the process of erosion. Features of a landscape are then cut upon the strata, and a record is made of the topographic aspects of the land. If the surface is again submerged, and stratified rocks are again laid down upon it, the evidence of interruption remains, and the two series of sedimentary rocks are said to be unconformable. It not infrequently happens that during the interval the underlying set has been deformed, has undergone more or less profound changes of character, and is evidently very much older than the overlying sequence. A great interval of time is then represented at the unconformity between the two rock masses, but the record of it can be compared only to torn or missing pages of an ancient manuscript.

Evidences of sedimentation or of erosion enable us to ascertain the succession of events in any one province, that is so far as we can trace and identify the same strata and the same unconformities, but this possibility is limited by many conditions. On comparing the sequences of strata, even of adjacent provinces, marked differences are found and the simply physical phenomena fail as a basis of correlation of events of history which occurred in separated regions.

A third principle rests upon the evolution of organisms. Late in the 18th century an English engineer, William Smith, who was in charge of a canal dug across tilted strata in southern England, observed that many of the beds contained marine shells; that certain kinds of shells occurred particularly in the lower and older beds, and other kinds in the younger and upper beds; and that these differences as to the kinds of shells were definite and constant. Hence he concluded that wherever he might find shells characteristic of a certain stratum he had a representative of that particular bed, even though he could not trace its continuity from place to place. Thus William Smith laid the foundations for one of the great generalizations of geology, which is that in sediments of each epoch of the earth's history since life began were buried the remains of creatures characteristic of that general time; and these remains becoming fossilized serve to identify the strata in which they may be found with the epoch during which the organisms lived. Hence it follows that fossils are used to compare and correlate the events of geologic history in one province with those in another province within any one continent, and also from continent to continent. But correlation even by faunas is not an accurate matching. Faunas of different provinces are rarely closely alike, their migration has been influenced by physical changes, their evolution depends upon the environment which was undergoing change and was shifting. Correlation by faunas, therefore, involves comparisons of developing migrating associations whose likenesses are derived from a more or less nearly related common stock or stocks. Like methods of correlation by physical evidence it is of highest value only within short range; but of all methods, it is that which at present must be relied on for the greatest ranges.

Great sequences of strata, each of which is characterized by peculiar associations of fossils, have been found throughout Europe, and parallel sequences have been identified throughout North America. In other continents also closely related systems of strata are known. Each great sequence thus marked by peculiar remains of life is named and is thought to correspond to a particular geologic period, although the limits of time divisions are indefinite to the extent that correlation is approximate. The errors, however, are small in comparison with the vast lapses of time represented, so that we may say with Huxley that geologic systems were relatively contemporaneous, though not absolutely so.

The recognized systems are enumerated below in the order in which they would be found in a column were they all to occur in any one province, the oldest at the bottom, the youngest at the top. Their names are taken in most instances from districts in which the strata occur typically, or from characteristics of the rocks themselves. The time division corresponding to a system is here called a period. Periods are grouped to constitute eras, and these are named according to the condition of development of the living forms, except the first, the lifeless era. Thus we have the Azoic, lifeless era, the Eozoic, dawn life era (or the Proterozoic, fore life era, or Agnotozoic, unknown life era), the Paleozoic, ancient life era, the Mesozoic, middle life era, and the Cenozoic, modern life era.

Each system is divided into series, some of which have received names that are used alike in Europe, America, and elsewhere wherever the fossils characteristic of the series are found, while others are identified by name in a particular province only. The Quaternary is divided into Pleistocene and Recent, the former term designating collectively the Glacial epochs. The Tertiary of Europe and North America includes the Eocene, Oligocene, Miocene, and Pliocene series, enumerating from earlier to later. These cover the most familiar cases of

Within each series there are many minor subdivisions which represent conditions in local districts of each province, and for these again distinctly local names must be chosen. The common practice is to give to each such minor division of a rock sequence the geographic name of a place at or near which the particular formation is to be seen in typical character, and this name is applied to that formation as far as the latter can be traced continuously. There was formerly an attempt to recognize the details of geologic systems throughout wide areas, even throughout continents. The geology of North America having been studied first in a thorough manner in New York State, names which were selected from New York localities were applied to formations in distant territories. The "Potsdam sandstone" and the "Trenton limestone" are much-abused examples of this practice. But it has been found necessary to recognize the great complexity of the geologic record by giving distinctive names, and the labor of reducing the multitudinous details to that orderly historic record which they no doubt express must proceed slowly with the development of more complete knowledge of the physical and biological conditions of the past.

Aspects of Physical History.— No attempt can be made to condense an account of geologic history into these few paragraphs, but a general view of the subject may be given. We have seen, in considering geologic processes, that deformation is the initiative process, and that all other phenomena are more or less remote effects of the gravitation of the earth's mass toward its centre. Therefore the first question we may put to the historic record is: What have been the chaanges in the internal energy of the earth during recorded geologic time? The commonly accepted view that the earth has cooled from an excessively heated condition, since the formation of the oldest known rocks, is not sustained by geological evidence. It is true that the oldest rocks — those of the Archean — are predominantly igneous rocks, that is to say, they have crystallized from a molten state. There is, however, abundant evidence that the areas in which they are now observed have been very deeply denuded in process of erosion, and therefore that these ancient rocks have come to the surface from great depths, at which at the present time similar rocks are presumably quite as hot as they were. The igneous character of these ancient rocks is, therefore, entirely consistent with the hypothesis of a cool surface at the time of their crystallization. Moreover, there occur with them small but significant amounts of sedimentary rocks, which in chemical and mechanical characters resemble those of later, even of the latest, epochs, and which therefore indicate that the conditions of temperature were not markedly different from those which now exist. We may consider it improbable that the internal energy of the earth has since the beginning of the Algonkian undergone such great changes as are commonly conceived.

Again, it is frequently supposed that the earth's energy as expressed in the development of mountain ranges, was far more intense and effective in earlier geologic periods than now. But each epoch of mountain growth, and there have been many, is recorded in the sediments which resulted from erosion of the uplifted land masses, and from the volume and character of the sediments we may infer the magnitude of the uplift. Studied from this point of view, the sedimentary strata give no reason to suppose that mountains greater than those which now exist have ever diversified the surface. On the contrary, it appears that there have in the past been long ages during which no mountains developed, and that these ages alternated with epochs of shorter duration, during which mountain growth was an active phenomenon. The Algonkian period, whose duration was probably equal to that of all time since its close, may have included several such alternations of quiescence and activity. It certainly was in some districts, as in that of Lake Superior, characterized not only by vigorous but even by volcanic mountain growth. The Cambrian and Ordovician periods, on the other hand, were not thus marked, and sediments, changing as they do from the mechanical products of erosion to those of a marine origin laid down in widespread seas, indicate that the land stood long at a constant level with reference to sea, and that the elevations of an early date were later reduced to wide plains, which were submerged as they subsided. During the Silurian and Devonian there were cycles of erosion resulting from local uplifts, in alternation with epochs during which the processes were relatively at rest; but these appear to have been of shorter duration. The greater part of the Carboniferous, from its earliest epoch on toward the close, was, like the Cambrian, a time of constant level, followed by subsidence of lands and expansion of seas. The closing epoch of the Carboniferous period and of the Paleozoic era initiated an activity which continued into the Triassic and resulted in extensive lands diversified by mountain chains.

During the Jurassic and Cretaceous these were eroded to low plains, and the surfaces of the lands were widely submerged beneath the broad Cretaceous seas. The Tertiary, like the Upper Silurian and Devonian, had its minor cycles, culminating in a broader extension of the lands; and at the present time we live in an epoch of vigorous mountain growth, when the aspects of the earth are most varied and the conditions of environment and climate are most favorable to a great variety of plants and animals.

Much stress has been laid upon sedimentary rocks in the preceding brief statement, because it is through the orderly relations of stratified beds, and through the fossils which they contain, that we are able to make out something of the geologic record.. In order that the reader may gain a clearer idea of the manner of distribution of sediments following upon the great fluctuations in the distribution of lands and seas, the following maps of North America showing the geographical conditions of widely separated epochs, are herewith introduced.

Paleography is that branch of geology which deals with the geography of past times. The appended paleographic maps of North America are based on physical and faunal evidence, which is acceptable as showing the general geographic condition during a geologic age; they are not refined enough to give the geography of a particular epoch. The limits of seas and lands, even where most accurately mapped, were changing, and in no case can one of these maps represent the geography of the continent at a definite date.

FIG. 1.— Geography of North America during the early Cambrian. Preceding this stage land areas had long been extensive; following this stage they became less by general planation and submergence.

Aspects of Climatic History.— Climatic conditions of the past are known to have been variable. There are evidences of extremely luxuriant plant growth, indicative of warm and moist climates, and in alternation with these occurred ages during which chemical sediments, such as salt and gypsum, were laid down in quantities consistent only with great aridity.

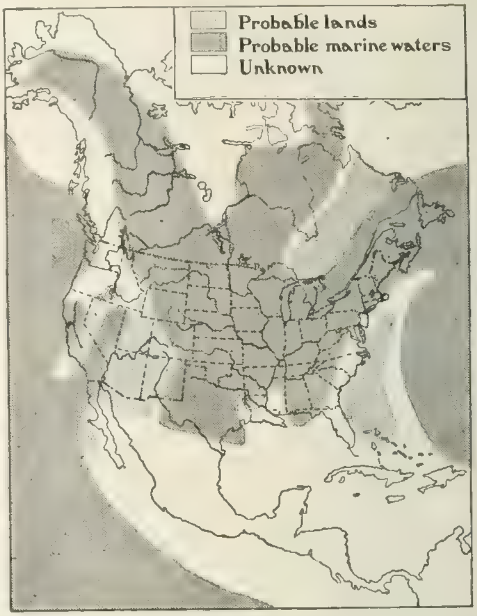

FIG. 2.— Geography of North America late in the Ordovician. About this time the continent was probably more extensively submerged than at any later epoch; extensive emergence followed.

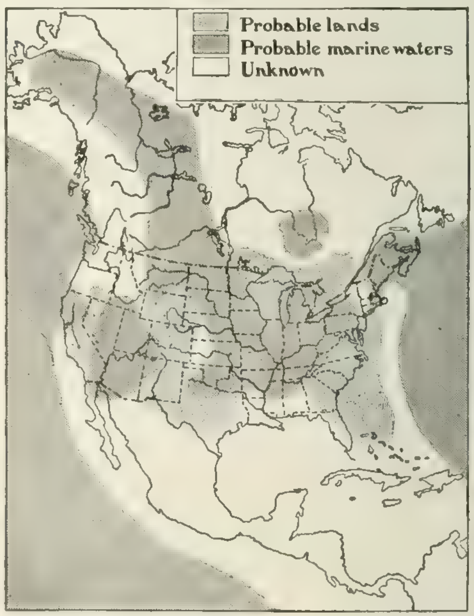

FIG. 3.— Geography of North America late in the Devonian. Preceding this stage land areas had been more extensive, particularly in the eastern United States; following this stage the seas expanded to the condition shown in the next map.

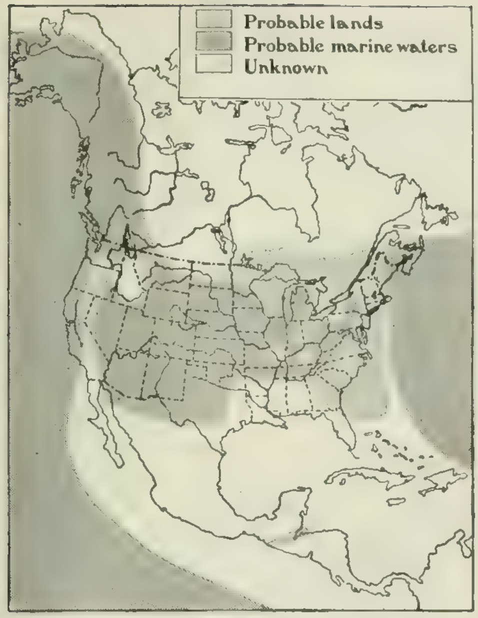

FIG. 4.— Geography of North America during the Mississippian age. At this stage the late Paleozoic seas probably had greatest extent.

Again, there are records of tropical vegetation within the present Arctic Circle, and also of a general ice mantle extending in Europe and America as far south as the fortieth parallel of latitude. Extensive glaciers occurred in Aus-

FIG. 5.— Geography of North America during the Pennsylvanian (Coal Measure) age. Preceded by more extensive seas, this stage was characterized by emerging lands. Marsh, river, and marine deposits alternate in areas shown as fresh water.

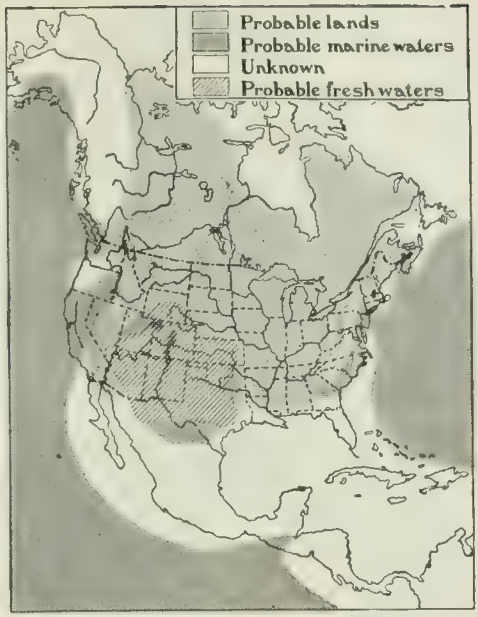

FIG. 6.— Geography of North America during the Permian and Triassic ages. This map represents the passage of the continent from Paleozoic to Mesozoic aspects. From Mississippian to Triassic time the net effect of conflicting movements was the general withdrawal of marine waters from the continent, and the later stages of that phase are here represented. Marine deposits also occur in fresh water areas.

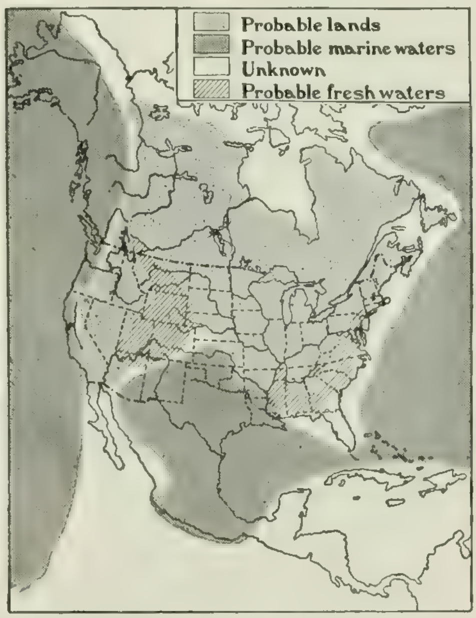

FIG. 7.— Geography of North America during the Lower Cretaceous. Preceding this stage, namely, during the early Mesozoic, land areas had been more extensive than at any time since Algonkian. This map represents the first stage of the Cretaceous submergence which increased to its maximum, see next map.

FIG. 8.— Geography of North America during the Upper Cretaceous. This map represents the culmination of the submergence which occurred during Cretaceous time.

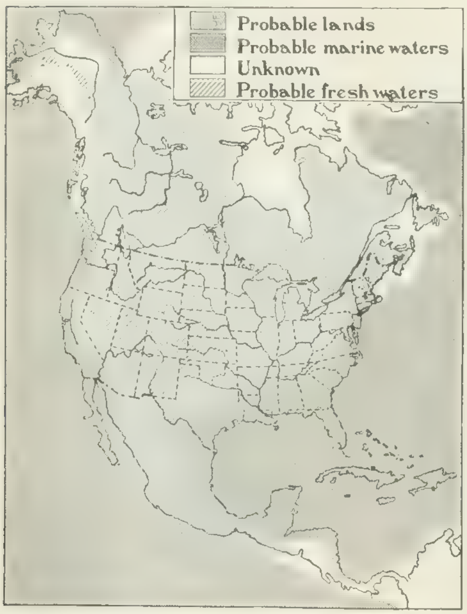

FIG. 9.— Geography of North America during the Tertiary. Accompanying the withdrawal of marine waters from the areas over which they had spread in Cretaceous time, there were effective mountain growths which continued intermittently through the Tertiary and into the Pleistocene, and which resulted in the present distribution of ranges. In the provinces of the Rocky Mountains and Great Plains river and lake deposits of unusual extent accumulated. The map is a composite picture, not one of any definite stage.

tralia and South Africa late in Carboniferous time, where but a short time previously tropical conditions had prevailed, as they do now. Various hypotheses have been framed to account for these special conditions, some of them depending upon changes of astronomical relations of the earth to the sun, others upon altitude of lands above sea, and one upon the constitution of the atmosphere. The last named appears at present to afford the most reasonable basis of explanation, though the hypothesis is by no means established as true in all its phases. It rests upon the physical and chemical properties of carbonic acid (CO_2), and upon the fact that this substance is present in our atmosphere in very small quantities. Physical researches have shown that even the small amount present has a potent influence in absorbing the heat of the sun and raising the temperature of the atmosphere. That is to say, it thickens the atmospheric blanket about the earth. A slight in-

FIG. 10.— Geography of the Pleistocene ice sheets in North America. During the Pleistocene ice sheets developed about three centres in northern Canada and with fluctuations sufficient to characterize several glacial epochs extended at their maximum to the limits shown on this map.

crease in the minute percentage present would suffice greatly to extend the climatic conditions of the temperate and tropical zones toward the north and south poles, whereas a diminution to one half of the present quantity would bring on the conditions of the glacial epoch. Carbonic acid is the most active reagent of the atmosphere entering into decomposing rock masses, and must be taken into combination in relatively great quantities during periods of active erosion. When so combined it occurs in solution in waters in the form of bicarbonates, and in large part passes to the sea. As periods of erosion are not indefinitely continued, but in course of time cease through the activity of the very agencies of erosion, that process runs down, and in time the absorption of carbonic acid becomes relatively insignificant. The

amount of carbonates conveyed to the sea may, however, by that time have been sufficient greatly to promote the activity of organic and chemical agents, through which monocarbonates are deposited, especially as limestone, and the second molecule of carbonic acid is set free. The latter is then returned to the atmosphere, which may thus become re-enriched. This idea is the central one of the carbonic acid hypothesis of climatic variation; but with it are combined many auxiliary facts and conditions which greatly strengthen it and serve to explain many of the minor cycles of variation whose record is noted in the rocks and in the life forms which they contain. The whole hypothesis rests upon the periodic activity of the earth's internal forces, already described in speaking of the growth of continents and mountain ranges; and thus climatic change is traced to deformation, the initiative process of all physical conditions of the earth.

It is estimated somewhat indefinitely that 40,000 years have passed since the climate was such that the southern part of the latest great ice sheet occupied Lake Erie and, retreating, permitted the cataract of Niagara to begin its existence at Lewiston. From that place the river has since cut back its gorge to the present site. That time, 40,000 years ago, may be regarded as the close of winter in one of the great cycles of climatic change. It would be interesting to know how long the seasons of that cycle are. Are forty thousand years a month, a springtime, or more? Do we live in the early vernal season of a great era and is the climate to grow warmer during many tens of thousands of years to come? Or is the summer of this cycle well advanced and will a glacial winter again sheathe the north temperate zone in ice?

Aspects of Organic Environment.— The evolution of organic life is properly a subject for distinct treatment, and not to be considered in this connection, except to point out the influence which changes of environment may have had. As far back as early in the Algonkian period, that is to say near the beginning of well-recognized geologic history, there were deposits of carbonates and of carbonaceous material which seemed to indicate the existence of organisms, and trails made by some low forms crawling upon soft mud are abundant in later Algonkian strata. The beginning of the Cambrian period is, however, the first time at which fossils were preserved in large numbers and of varied species. Six of the nine classes of creatures now recognized are represented in strata of that period, and the vertebrates appeared in the next. The other two classes are not of such organisms as would leave remains likely to be preserved. The variety and exuberance of life shows that evolution had been going on during long ages prior to the Cambrian, and that conditions had long been favorable for organic activity. In this connection it should be noted that during the Algonkian, so far as the record goes, land areas had been extensive and sea basins had probably been correspondingly deep and limited. During the Cambrian and succeeding Ordovician periods, occurred one of the greatest submergences not only of North America but also of Europe, and the expanses of shallow seas afforded great realms in which the conditions were favorable to life. These two periods are also characterized the world over by a predominance of deposits of limestone, which according to the atmospheric hypothesis above suggested should have resulted in warm climates appropriate to exuberant life development.

If we were to trace the great changes in living forms which occurred in passing from the Ordovician to the Devonian, from the Carboniferous to the Triassic, from the Cretaceous to the Tertiary, we should find that each accompanied and probably resulted from the great variations of habitat and of climate. Epochs during which seas were wide and temperatures high promoted development and resulted in great diversity of genera and species. Epochs during which seas were limited to deep basins afforded very narrow areas in which competition was fierce and opportunity limited, and the low temperatures resulting from erosion of extended land areas were unfavorable. It is along these lines of suggestion that the geologist is now seeking for the explanation of the stages of organic evolution and of the unequal progress which has been made from one age to another.

APPLIED GEOLOGY.

Scope of the Subject.— The scientific principles of geology relate to rocks and minerals which are useful to man and afford a means of determining their origin, their forms of occurrence and extent, and the peculiar relations of rock masses or structure which have led to concentration, notably of metallic ores. All classes of mineral products fall within the scope of applied geology. Gravels, sands, and clays of surficial deposits, massive rocks quarried for building and ornamental purposes, coals, and other bedded strata, and the ores of iron and of the precious metals, all these are products of genetic conditions which when understood afford clues that promote discovery and direct exploitation. Inasmuch as only exceptional occurrences are valuable, whereas it is generally supposed that mineral wealth is common, the service of applied geology is as frequently to prevent unprofitable operations as to aid those which may yield results. The essential knowledge belongs in part to each of the sciences of geology, mechanics, physics, and chemistry, and to be reliable should be aided by wide experience in observations underground, as well as of geological phenomena in general. The application of principles must rest upon an intelligent understanding of the conditions of formation of a rock mass or deposit, and accordingly economic minerals are classified by the conditions of genesis.

Classification of Economic Minerals.— Classifications of economic minerals, and especially of ore deposits, have been much discussed, and are still debated. One which is adequate for all general purposes follows the classification of rocks already given, and comprises three classes of economic rocks and minerals: Those of igneous origin, those of sedimentary origin, and those of chemical origin by the agency of underground waters.

Igneous rocks have value as useful and ornamental stones, such as granite, serpentine or verde antique, trap rocks for road metal, etc., and occur in large masses, which as a rule are quarried by the simplest processes. Metal-

liferous ores, which are directly of igneous origin, though commonly supposed to be most abundant, are in fact of limited occurrence. Titaniferous iron ores such as are found in the Champlain district of New York, are igneous rocks peculiarly rich in iron. Ore bodies of other metallic compounds in some instances occur in such relations to igneous masses as apparently to have been formed from gases or waters accompanying the eruptions; but the chief part which igneous rocks play in relation to ores lies in the fact that they contain the metals in appreciable though minute quantities, and yield them to underground waters by which the metalliferous minerals are concentrated in ore bodies.

The class of sedimentary deposits of value includes many clays, sands, building stones, etc.; some iron ores; and coals. The class is characterized by the stratified structure of all materials contained in it. The strata are usually of great extent and moderate thickness, and their dimensions may be observed by tracing and measuring them throughout their appearance at the surface, or outcrop. From these observations the distribution of the strata where they extend beneath the surface, even to considerable depth, may be inferred. It may easily be understood how this method of looking underground is applied to any one tilted stratum, such as a coal bed; and though the operation becomes more complex, the principle remains the same when many beds of known succession are considered. The same method of observing the normal succession and thickness of strata and of drawing inferences as to the extent of formations underground is applied in districts where the layers have been bent into forms of troughs and arches, which are usually long, narrow, and parallel. Any stratum occurring at the surface bears known relations to all those below it, and thus the depth to any other stratum beneath any particular one seen may be estimated. Through many such estimates the form of the trough corresponding to any one stratum may be worked out and delineated by maps, drawings, or models. These principles, based on the regularity of stratification and of sequence of strata, are of most service in regard to coal beds and artesian waters, serving in the former case to afford a basis on which the amount of coal and the methods of mining may be determined in advance; and in the latter case to determine the depth at which an artesian flow of water may be reached. Good topographic and geologic maps are essential preliminaries to such economic investigations if the latter are to be reliable and of value.

Ore Deposits through Underground Waters. — Underground waters circulate deeply downward, laterally and upward in the earth's crust. They dissolve constituents of nearly all minerals, including gold, some of them readily, at surface pressures and temperatures, others in notable quantities only at pressures and temperatures of deeper zones. In circulating they bring together solutions which may differ in composition and may cause chemical reactions; or they may bring solutions into contact with wall rocks that exert similar chemical influences. The results are precipitation of metalliferous minerals in cavities, or the replacement of the wall rock itself by the ore. To these activities most ore deposits are due.

The metallic elements are contained in igneous rocks which are the original sources, but usually in minute quantities and disseminated through large masses and in compounds not available as ores. The universal combinations of iron and other bases with silica are obvious examples, as is also the frequent occurrence of pyrites or "fool's gold." Processes of chemical alteration, solution, and deposition are necessary steps toward concentration, and they may be more or less complex or often repeated. The reagent which accomplishes these chemical reactions is primarily that rain water which percolates beneath the surface and becomes ground water. Charged with oxygen and carbonic acid, it enters the superficial part of the zone of fracture, and is there active in producing oxides and carbonates and displacing silica, as already described. The important reaction upon metalliferous ores is the oxidization and carbonation of sulphides. Descending through the zone of cementation, where it may deposit much or all of the substances taken into solution, the water is warmed or heated, and is under constantly increasing pressure as it sinks deeper. It thus becomes a more active solvent for metalliferous minerals, and in the deep zone of recrystallization, where the movement is through capillary and subcapillary spaces, and is very slow, it may become even more potent. Its course in circulating, however deep and roundabout, is toward an outlet at the surface, and is ultimately upward. Among the ascending waters there may well be those which have escaped from the magmas of the interior and with substances in solution have joined the meteoric waters. The circulating underground solutions are directed in movement by the spaces in and between rock masses, spaces which are very minute in the deeper part of the zone of flow and fracture, and which are larger in the stronger rocks and nearer the surface. The larger ones, which are called trunk channels, are those in or near which ore bodies may form. The courses of descending and ascending waters are also controlled by relatively impervious beds, such as strata of clay, or shale, or schist, which may be too weak to maintain openings and too dense to absorb solutions. The spaces between rock masses are usually effects of deformation, fissures, faults, and folds, which are detected and traced through the fact that along them the rocks have departed from the relative positions or succession which they originally had, or have been brought into contact by intrusion, in the case of eruptive rocks. To understand the character of the structure, whatever it may be, involves primarily an understanding of the nature and original relations of the rock masses.

Large ore bodies if developed in open spaces can only occur in the zone of fracture and in the upper part of the zone of flow and fracture. If they are formed by replacement of the country rock by metalliferous minerals, their limits are determined by the mechanical, physical, and chemical conditions that in the individual case favored replacement. The relative parts played by descending, ascending, and laterally flowing solutions are unlike in the different cases, but are of practical significance in estimating the position and extent of ore bodies. The chemi-

cal reactions which may result in formation of ore minerals from gases, from solution, or by replacement, are controlled by pressure, temperature, and environment, in ways that are not fully understood and that are being actively investigated. It is, however, clear that the exceptional concentrates are to be sought in general in regions of disturbance, and, so far as the precious metals are concerned, especially in districts affected by intrusive igneous rocks; further that ore bodies are usually related to water channels which may best be followed through an understanding of the structure by which they were determined; and that within ore deposits processes of oxidation, carbonation, solution, and reprecipitation are in progress and produce the richest accumulations of ores.

II., 1892); Wright, 'Ice Age in North America' (1893); Zittel (Eastman's), 'Text-Book of Paleontology' (1896).

General Bibliographies.— The literature of the several branches of geological science is voluminous, but there are many articles published in serials which are of interest to the general reader. Reference to all the literature may be had through the following bibliographies: Darton, 'Catalogue and Index of Contributions to North American Geology 1732–1891' (Bull. U. S. Geol. Survey No. 127); Warman, 'Catalogue and Index of the Publications of the United States Geological Survey 1880–1901' (Bull. U. S. Geol. Survey No. 177); Weeks, 'Bibliography of North American Geology, Paleontology, Petrology, and Mineralogy for the years 1892–1900, Inclusive' (Bull. U. S. Geol. Survey No. 188).

The official bulletins, annual reports, and professional papers of the United States Geological Survey contain many special articles, and may be had on application to the director, Washington, D. C.

BAILEY WILLIS,
U. S. Geological Survey.

Geomancy, jē'ō-măn-sĭ (Greek, *gē,* the earth, and *manteia, divination*), a kind of divination formerly practised. Sparry, in his translation of Cattan's 'Geomancie' (written about the middle of the 16th century, and translated in 1591), says: "Geomancie is a science and art which consisteth of points, prickes, and lines made instead of the foure elements, and of the starres and planets of heaven. . . And this arte may be made on the earth or on white paper, or uppon any other thing whereon it may commodiously be done, so that the prickes and lines may be knowen." See DIVINATION; FUNG-SHUI.

Geomet'rical Mean of two numbers is that number the square of which is equal to the product of the two numbers; thus, the geometrical mean of 9 and 16 is 12, for $9 \times 16 = 144 = 12^2$. Hence the geometrical mean of two numbers is found by multiplying the two numbers together and extracting the square root of the product.

Geometrical Optics. See MIRROR; LENS; OPTICS.

Geometrical Progression. A series of quantities is said to be in geometrical progression when the ratio of each term to the preceding is the same for all the terms, that is when any term is equal to the product of the preceding term and a factor which is the same throughout the series. This constant ratio or factor is termed the *common ratio.* See PROGRESSION.

Geometridæ, jē-ō-mĕt'rĭ-dē, a family of moths whose larvæ walk by arching the body and so bringing the hinder feet (prolegs) close up to the forward (thoracic) feet, and again reaching forward. Hence they are called "loopers," "inch-worms," etc. See MEASURING-WORMS.

Geometry. The characteristic aspiration of scientific man is to conceive the universe as a genuine cosmos. Of scientific generalizations, one of the most obvious and important, and one which is at the same time historically among the first, has reference to *order,* namely, that the universe presents or at least suggests two grand order-types: order of coexistence or of side-by-side, that is, order-in-Space; and order of succession or of before-and-after, that is, order-in-Time. These seem to be logically independent. Which one, if either, is the more fundamental remains undetermined. The two combine to give the category of motion, and accordingly the world presents alike to the sense and to thought two complemental aspects, the static and the dynamic. To these and their combination correspond the fundamental sciences. The mentioned order-types taken in the abstract are the subject-matter of mathematics; the former yielding pure geometry, the latter pure analysis; the two together, analytico-geometry and geometrico-analysis.

By perusal of the articles that immediately follow, the reader may gain some notion of the wondrously diverse and manifold significance

assumed by the term geometry in modern times. The view thus gained may be further matured and enriched by reference to such other articles of this work as: CURVES, HIGHER PLANE; CURVES OF DOUBLE CURVATURE, THEORY OF; SURFACES, THEORY OF; MENSURATION; HYPERSPACES; ANALYSIS SITUS; QUATERNIONS; CALCULUS OF VARIATIONS, THE; CALCULUS, THE INFINITESIMAL; HARMONIC ANALYSIS; EQUATIONS, DIFFERENTIAL; INVARIANTS AND COVARIANTS. Some of these latter are indeed primarily analytic. They nevertheless serve to illustrate, not only the unity of mathematics in general, not merely the complemental relationship in which the two grand divisions, geometry and analysis, stand to each other, but in particular the universal pervasiveness of geometric concepts and methods.

CASSIUS J. KEYSER,
Adrian Professor of Mathematics, Columbia University.

Geometry, History of the Elements of. The history of the science of geometry begins in Greece. It is true that mensuration was developed to a considerable extent at an early period in Egypt, Babylonia, and India, and that this work involved the measurement of angles in the astronomical observations of the people of these countries, but the abstract science of form never attained any prominence before the Greek period. In Egypt, for example, the harpedonaptæ (rope stretchers) knew the right-angled triangle whose sides are 3, 4, 5, and stretched their ropes to lay out a right angle in much the same way that a modern surveyor erects a perpendicular by the help of his chain; but there is no evidence that the Egyptians thought of proving the Pythagorean theorem. Herodotus testifies to the fact that the Egyptians divided the land that was subject to the overflow of the Nile, into quadrilaterals, and therefore they must have had some knowledge of elementary surveying. Indeed, long before this time Ahmes (see ALGEBRA, HISTORY OF THE ELEMENTS OF) gave certain rules, partly incorrect, for measuring areas and volumes, in particular an interesting one for the area of the circle, $a=(d-\frac{d}{9})^2$. All of this work was, however, very elementary, and the rules were merely the result of unscientific observation.

In Greece the science of geometry may be said to have begun with Thales (q.v.), who was born at Miletus, c. 640 B.C., and who died at Athens in 548. Brought up in contact with the learning that drifted from the East to the shores of the Mediterranean, in his younger days devoted to those commercial pursuits that made Miletus a centre of wealth, he traveled extensively, and devoted his later years to philosophy. From Egypt he seems to have taken back to Ionia whatever of primitive geometry was known, and his school at Miletus was devoted to the study of philosophy, astronomy, and the science of form. Thales is supposed to have proved the propositions concerning the equality of vertical angles, the sides opposite the equal angles of a triangle, the determination of a triangle by one side and two angles, the bisection of a circle by a diameter, and the nature of an angle inscribed in a semicircle. His most famous pupil was Pythagoras (q.v.), who was born at Samos in 580 and died in southern Italy in 501. A man of great personal magnetism, a mystic, and versed in the lore of the Orient, Pythagoras made his school at Crotona, the mathematical centre of his time. Although none of his works are extant, if, indeed, he wrote any, it is known that he proved the famous theorem which bears his name (Euclid I., 47), a proposition known empirically to the Egyptians, at least for special cases. Pythagoras also gave much attention to the study of proportions and irrational quantities, always from the standpoint of geometry. He also knew the size of the angle of a regular n-gon, and the stellar pentagon was made the badge of his order.

The century following Pythagoras was one of discovery. Among the most noted geometers was Hippocrates of Chios, c. 440 B.C., who must not be confounded with the great physician who wrote on the mystic number 7. Hippocrates, who had come in contact with the Pythagoreans, wrote the first Greek text-book on mathematics, and designated the geometric figures by letters placed at the angles. To him is due the first example of the quadrature of a curvilinear figure, a proposition known as the lunes of Hippocrates. The theorem asserts that if semicircles be described on the three sides of a right-angled triangle in such way as to form lunes on the two shorter sides, the area of the lunes equals that of the triangle. In his attempt to duplicate the cube he showed that the problem can be solved if two mean proportionals can be found between e and $2e$, where e is the edge. This problem was one of the three famous ones of antiquity, the others being to square the circle and to trisect any given angle. It is now known that these problems, easily solved if the necessary instruments are allowed, cannot be solved merely by the use of an unmarked ruler and a pair of compasses. Contemporary with Hippocrates lived Hippias of Elis, to whom is probably due the quadratrix which Dinostratus afterward studied and named. About the same time Antiphon and Bryson sought the quadrature of the circle by means of inscribed and circumscribed polygons, the number of sides being successively doubled, and with them begins the theories of limits and of exhaustions.

The influence of Plato (429–348 B.C.) on elementary geometry was greater than is usually supposed. He found the science in a disordered state, a mass of unrelated propositions, very likely covering much of plane geometry as found in Euclid. His philosophic mind led him to the attempt to put the science on a more satisfactory foundation by insisting upon accuracy of definition, upon a limited number of postulates (including axioms), and upon definite bounds to plane geometry. As a result, only those figures capable of construction by the help of an unmarked ruler and the compasses are recognized as belonging to the field of elementary geometry. To the school of Plato is also due the analytic method of attack in geometry, including the *reductio ad absurdum.* Although not himself a great discoverer in mathematics, two of Plato's pupils reached high eminence in geometry. Of these the first was Eudoxus, who extended the theory of proportion, founded the doctrine of similar figures, gave much attention to the problem of the golden section, applied the method of exhaus-

tions to the mensuration of solids, and wrote the first text-book upon stereometry. The second was Menæchmus, who, in his attempts to solve the duplication (or Delian) problem, discovered the conic sections. The study of the five regular polyhedra also occupied the attention of Plato's pupils, so much so that they received the name of Platonic bodies.

The influence of Aristotle was directed to the encouragement of the study of the history of geometry and the applications of mathematics. As a result, his followers began to collate the work of the earlier Greeks and to consider its relation to physical problems. Elementary geometry now enters the text-book period, and several attempts at works of this character appear in the fourth century, B.C. This movement culminated in the works of Euclid (q.v.), a man of whose personal life we know practically nothing save that he taught and wrote in Alexandria c. 300 B.C. Probably of little originality in the way of mathematical discovery, Euclid had a genius for compilation, and this showed itself in the Στοιχεῖα (connected series), or *Elements*, as it was called in later times. This famous work is devoted principally to plane geometry, and it has formed the basis of practically all elementary treatises up to the present time. The natural effect of Euclid's work was to give the impression that the field of elementary plane geometry was exhausted. Mathematicians therefore directed their energies to the applications of geometry, to stereometry, and to conics. Archimedes (q.v.), writing at Syracuse c. 240 B.C., opened the great field of mathematical physics and carried the study of elementary geometric solids to its greatest height among the Greeks. To him is also due the limits $3\frac{1}{7}$ and $3\frac{10}{71}$ for π, the study of the spiral that bears his name, and the quadrature of the parabola. Apollonius of Perga (q.v.), "the great geometer," wrote eight books on conics c. 225 B.C., and set a standard which still influences the text-books in analytic geometry. Of the minor geometers who followed Apollonius, two may be mentioned. Nicomedes (c. 180 B.C.), who invented the conchoid, a curve which easily solves the trisection problem, and his contemporary, Diocles, whose cissoid furnishes an easy means for duplicating the cube. Of the later Greek geometers the most noteworthy is Hero of Alexandria (see HERO OF ALEXANDRIA), whose personal history, like that of Euclid, is practically unknown, and to whom it is difficult to assign a date even within a century. His most interesting contribution to elementary geometry is the formula for the area of a triangle in terms of the sides,

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)}.$$

Possibly contemporary with Hero lived Menelaus, whose theorem, known in the Middle Ages as the *Regula sex quantitatum*, has made his name well known. His most important discovery, however, was the projective property of the anharmonic ratio. By this time the age of discovery in geometry had passed in Greece, and the efforts of the Neopythagoreans at Alexandria were productive of little that is remembered. Pappus (c. 300 A.D.), an Alexandrian mathematician and geographer, may be called the last of the Greek geometricians who showed any originality. He suggested the theory of involution of points, restated the projective property discovered by Menelaus, and discovered the theorem (which also bears the name of Guldin) concerning the volume generated by a plane figure revolving about an axis.

The Orientals contributed but little to elementary geometry, their interests being rather directed to algebra (q.v.) and trigonometry (q.v.), with astronomy as the leading application for their advanced mathematics. Brahmagupta, a Hindu, born in 598, generalized the Hero formula, showing that the area of an inscribed quadrilateral is expressed by

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)},$$

but aside from problems in mensuration, geometry played but little part in India. The Bagdad school of c. 800 was chiefly interested in geometry only as it concerned trigonometry, and its greatest contribution to the science consisted in the preservation of the works of the Greeks. Euclid, for example, was first made known to Christian Europe in the Middle Ages through a translation from the Arabic by Adelhard of Bath, c. 1120.

Among the first books on mathematics to be printed was Euclid's 'Elements' (1482), a fact which made this famous work again a standard. The appearance of this classic had the same effect as in the later centuries of Greek culture, to encourage commentators rather than investigators. In the way of original work, only such minor efforts as the study of stellar polygons and the geometry of a single opening of the compasses characterized the closing decades of the Middle Ages and the opening years of the Renaissance. Not until Kepler (q.v.) suggested the principle of continuity (1604), and Cavalieri set forth the method of indivisibles (1629; published in 1635), and Desargues began the theory of modern geometry (1639), was there any material advance in the subject. When, however, this advance was undertaken it was so vigorous as to lead from elementary geometry to higher fields. In the latter part of the 19th century there was a renaissance of investigation in the elementary domain, leading to an interesting but not very productive study of the geometry of the circle and the triangle, notably in the work of Lemoine and Brocard. The 19th century also saw an exhaustive study of non-Euclidean geometries (q.v.), those based on other postulates than those of Euclid. This study began with the works of Lobachevsky and Bolyai (qq.v.), and has led to very interesting results, hardly to be ranked, however, in the domain of elementary geometry.

DAVID EUGENE SMITH.
Professor of Mathematics, Teachers College, Columbia University, New York.

Geometry, Cartesian.—Between number and the properties of number, on the one hand, and space and the properties of space, on the other, there is, strictly speaking, no *resemblance*; and the science of number, *i.e.*, algebra or analysis, and the science of space, *i.e.*, geometry, are essentially, psychologically, and logically independent doctrines. But despite their fundamental unlikeness and independence, there is between the two, broadly speaking, a fact-to-fact *correspondence*. For example, there subsists, or may be established, a unique and reciprocal, or one-to-one, correspondence between the real numbers and the points of a straight line or other curve; between the real numbers and the lines of a flat pencil (see PROJECTIVE GEOMETRY) or the tangents to a curve; between the pairs of real numbers and the points or the lines of a plane; between the triplets of real numbers and the circles of a plane or the points or planes of space; between the quartets (permutations four at a time) of the real numbers and the lines or the spheres of space (see LINE GEOMETRY AND ALLIED THEORIES). The theory of the correspondence thus simply exemplified, the logically organic body of propositions setting it forth, is the *science* called analytic or algebraic geometry. It is often called coördinate geometry from the fact that the set of numbers determining or corresponding to a geometric element are called the coördinates of the element. By virtue of the correlation between analytic facts and geometric facts, it is frequently possible, when facts of the one type are known, to infer the corresponding facts of the other, and so to investigate space analytically (algebraically, arithmetically) and to investigate number geometrically. Under either of these aspects, analytical geometry appears as a *method*: analytic investigation of geometry, geometric investigation of analysis. Usually it is the former aspect under which the doctrine is regarded, geometry being the subject-matter, and analysis the means or instrument of research.

The science presents numerous branches or varieties. These differ among themselves in various ways. Two varieties may differ in respect to what is often called their 'spaces,' *i.e.*, in respect to the domains, fields, regions, or extents (as curve, surface, space) containing the configurations with which they deal. Thus arise such distinctive designations as geometry of (on, in) a plane, or plane geometry, geometry on a surface or a curve, geometry of space. Again, a given 'space' or domain may be conceived in countless ways. It may be conceived as the assemblage of its points or of its lines or of its circles, and so on. Accordingly two geometries relating to a same 'space' or domain may yet differ in respect to their *primary* elements, in respect, *i.e.*, to the elements of which the configurations investigated are regarded as composed. So arise, for example, such distinct theories as the point, line, circle, . . . , geometries of the plane, and the point, line, plane, circle, sphere, . . . , geometries of space. Once more, as will appear in this and related articles herein cited, a chosen element in any given domain may be referred to different kinds of configurations of reference; it may, in other words, be determined by, made to correspond to, or be associated with, different kinds of *coordinate systems*. Upon the choice of coordinate system depends, *ceteris paribus*, the analytic form of a given geometric theory. Accordingly, two geometries that are identical in content may differ in form, in algebraic guise or garb.

The primitive, by far the oldest, variety of analytic geometry, the parent of all other varieties, is the Cartesian, so called from its founder, René Descartes (1596–1650). Though originally a plane geometry, its procedure is equally adapted, and has been extended, to spaces of every dimensionality in points (see HYPERSPACES). It is characterized partly by its primary element, the point, and partly by its coordinate system, which will be explained below. Descartes' geometry, contained in his *Discours de la méthode pour bien conduire sa raison et chercher la vérité, dans les sciences*, published in 1637, is to be regarded, on account of its influence on mathematics and upon knowledge in general, as one of the very greatest contributions ever made to science. Descartes was not indeed the first to apply algebra to geometry. That had been done by «the great geometer,» Apollonius of Perga (about 260–200 B. C.), who had referred the conic sections to their tangents and diameters, expressing the relations by linear equations between areas. In the 14th century Oresme and others had applied numbers («latitudo» and «longitudo,» precursors of the modern ordinate and abscissa) to refer a point to two chosen rectangular lines or axes. The point was confined, however, to the first quadrant. In this way the straight line, the circle and the parabola were studied. Other predecessors of Descartes were Vieta (1540–1603), Cavalieri (1598–1647), Roberval (1602–1675), and the brilliant Fermat (1601–1665), who more nearly than any other approaches Descartes in his understanding of the analytic method. Even Fermat, however, had apparently not seen, what Descartes saw, the possibility of referring at once to a single coördinate configuration different curves of different orders.

The following paragraphs give a very brief account of the elements of Cartesian, or ordinary analytical, geometry with special reference to the straight line and the conic section and the simplest configurations of space.

THE PLANE.

Cartesian Coordinates.—Any two straight lines, as XX' and YY', are assumed as lines of reference, or *coordinate axes*. The former is X-axis or axis of *abscissæ*, the latter is Y-axis or axis of *ordinates*. The point O is the *origin* of *distances;* the (half) line OX, the *origin* of *angles*. Distances on or parallel to the X-axis are regarded *positive* (+) if measured *rightward*, *negative* (−) if *leftward*. Distances on or parallel to the Y-axis are regarded *positive* if measured *upward*, *negative* if *downward*. Angles are regarded *positive* or *negative* according as they are conceived to be generated by *counter-clockwise* or by *clockwise* rotation. (See TRIGONOMETRY.) Conceive drawn all lines parallel to the X-axis and all parallel to the Y-axis. Any pair of these lines, one of the former set and one of the latter, determine (intersect in) a point, and all points of the plane are thus determined. Conversely, any point

determines (is the common point of) a pair of the lines, and all the pairs of the parallels are

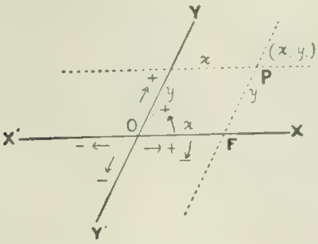

FIG. 1.

thus determined. Obviously any line-pair or its *point* determines two real numbers: the distances OF and FP in terms of any convenient unit. These, denoted respectively by x and y, are named respectively the *abscissa* and the *ordinate*, together the *coordinates*, of the point. Conversely, any *pair* of real numbers determine a point. It is thus seen that, by means of a pair (system) of axes, a one-to-one correspondence is established between the *points* of the plane and the assemblage of real number *pairs*. Any such point and its pair of coordinates are said to *correspond*; the point is said to depict or represent its pair of numbers geometrically, and the number pair is said to represent the point arithmetically or algebraically or analytically.

Transformation of Cartesian Coordinates.—It is plain that (the unit being the same) the coordinates of a point referred to one pair of axes will not coincide with its coordinates referred to a different pair. Formulæ for expressing the old in terms of the new coordinates are exceedingly useful. To find such formulæ, consider first the case where the old and new origins coincide. Denote by α and β the angles made with OX by OX' and OY' respectively. Let x and y be the old, and x' and y' the new, coordinates of any point P, and denote the

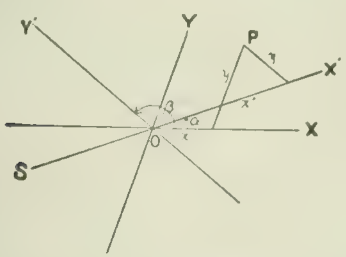

FIG. 2.

angle XOY by ω. The formulæ in question are readily seen to be: $x \sin \omega = x' \sin (\omega - \alpha) + y' \sin (\omega - \beta)$, $y \sin \omega = x' \sin \alpha + y' \sin \beta$. If the origins do not coincide and if h and k be the coordinates of the new origin O' with reference to the old axes, the formulæ of transformation are found by adding $h \sin \omega$ and $k \sin \omega$ respectively to the right-hand members of the foregoing equations. Most commonly the axes are assumed to be *rectangular*. In that case, $\omega = 90°$, $\sin \omega = 1$, $\beta = (90° + \alpha)$, and the equations of transformation become: $x = x' \cos \alpha - y' \sin \alpha + h$, $y = x' \sin \alpha + \cos \alpha + k$. The equations for effecting the *inverse* transformation are found by solving for x' and y' the equations of the *direct* transformation.

Polar Coordinates.—Though it is never necessary, it is often convenient, to employ other than Cartesian coordinates to determine the position of a point. Of such other coordinate systems, the most familiar is the *polar*. About any point O (as center), called the *pole*, suppose drawn all possible concentric circles; also suppose drawn out from the pole all possible *rays* (half-lines). Any circle and any ray determine (intersect in) a point, and all points of the plane are thus determined; conversely, any point determines (is common to) a circle

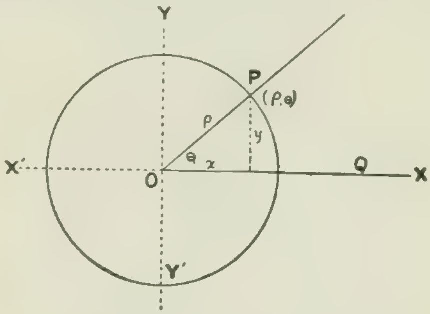

FIG. 3.

and a ray, and all pairs of such lines (circle and ray) are thus determined. A circle is given by its radius ρ, and a ray by its angle θ made with a fixed ray, as OQ, called the *initial line* or *polar axis*. All the circles are obtained by letting ρ vary from 0 to ∞, and all rays by allowing θ to vary from 0 to 2π or 360°. Obviously, to any pair of values (within the ranges of variation mentioned) of ρ and θ there corresponds one point, and conversely. The pair of numbers (ρ, θ) determining or determined by a point P are called the *polar coordinates* of P. In particular, ρ is called the *radius vector*, and θ the *vectorial angle*, of P.

Transformations from Cartesian to Polar Coordinates.—We present here only the simplest and most important case, *viz.*, that wherein the Cartesian axes are rectangular, the origin coinciding with the pole, and the positive half of the X-axis with the polar axis. Let P be any point. It is clear, Fig. 3, that the equations of direct transformation are: $x = \rho \cos \theta$; $y = \rho \sin \theta$. Solving these for ρ and θ, the equa-

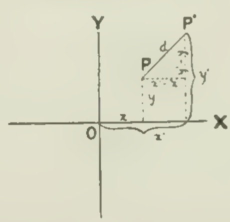

FIG. 4.

tions of the inverse transformation are found to be: $\rho = \sqrt{x^2 + y^2}$; $\theta = \tan^{-1}\frac{y}{x}$.

Distance between Points.—Henceforth the axes will be assumed to be rectangular. Let P and P' be any two points, of coordinates

(x, y) and (x', y') respectively. From Fig. 4, by the Pythagorean theorem, $d^2=(x-x')^2+(y-y')^2$, whence the distance between any two points (x, y) and (x', y') is found to be $d=\sqrt{(x-x')^2+(y-y')^2}$. Transforming to polar coordinates (ρ, θ) and (ρ', θ'), and reducing, there results $d=\sqrt{\rho^2+\rho'^2-2\rho\rho' \cos(\theta-\theta')}$, in agreement with the Law of Cosines. (See TRIGONOMETRY.)

Division of Line-segment in Given Ratio.— Suppose P divides the segment P_1P_2 in the

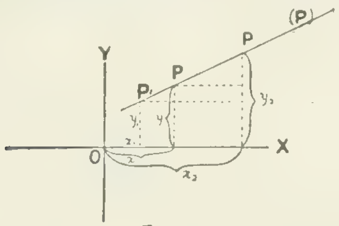

FIG. 5.

ratio, $m_1:m_2$. By hypothesis, $P_1P:PP_2=m_1:m_2$; hence, from similar triangles,

$$m_1:m_2=(x-x_1):(x_2-x)=(y-y_1):(y_2-y);$$

these equations, solved for x and y, yield

$$x=(m_1x_2+m_2x_1):(m_1+m_2)$$

and $$y=(m_1y_2+m_2y_1):(m_1+m_2).$$

If the division be *exterior*, *i.e.*, if P be *outside* the segment, as at (P), one term of the ratio is negative, and the formulæ are

$$x=(m_1x_2-m_2x_1):(m_1-m_2),$$

$$y=(m_1y_2-m_2y_1):(m_1-m_2).$$

If P be the interior mid-point, $m_1=m_2$, and $x=(x_1+x_2):2$, $y=(y_1+y_2):2$. If $m_1=-m_2$, P is the exterior mid-point and its coordinates are both infinite unless the segment is parallel to an axis, in which case but one of the coordinates is infinite.

Locus of Equation.—An equation, $f(x, y)=0$, between the variables x and y, *defines* a system or aggregate or assemblage of *pairs* of numbers, *viz.*, the assemblage of pairs of values of x and y that satisfy the equation. To each of such pairs of (real) values, a system of axes and a unit of distance being chosen, there corresponds a point. The assemblage of all the points so determined constitute the (real) *locus* of the equation. In general, as x or y varies continuously, y or x will vary continuously, and accordingly the corresponding point will trace a continuous path, some *curve*, the locus in question. Conversely, if a point move subject to some geometric condition, its path will be a curve such that the coordinates of its points and of no other satisfy some equation. An equation and its locus or curve are each said to represent the other, and, from the properties of either, corresponding properties of the other can be inferred. An equation defines its locus, a locus defines its equation. Any equation, $f(x, y)=0$, is, of course, satisfied by countless pairs of values of which either (or both) is imaginary or complex. To such a pair no real or «visible» point of the plane corresponds. Nevertheless, in order that the geometric and analytic languages shall be coextensive, it is customary to say that any pair of numbers of which at least one is complex represents an «imaginary point» of the plane. Accordingly the locus (in generalized sense) of an equation is composed of a real part and an imaginary part, the latter consisting of all imaginary points whose coordinates satisfy the equation. The intersection of two loci or curves consists of the points (real and imaginary) whose coordinates satisfy the equations of both curves. The foregoing remarks respecting equations in Cartesian coordinates apply equally to equations in polar coordinates.

The Straight Line and the Linear Equation.— Let (1) be any line through the origin, and denote by θ its angle with OX, and let $m=\tan\theta$. Obviously the x and y of any (every) point of (1) and of no other point are connected by the equation $y=mx$, which therefore defines, and is called the equation of, line (1). To each line through O there corresponds one value of the *slope* m, and conversely. Any line not through O is parallel to a line through O. Hence (2), parallel to (1), represents any line not through O. Clearly by adding b to any y of (1) the corresponding y of (2) is found, while corresponding x's are the same. Hence the equation of (2) is $y=mx+b$. The quantity b is called the *Y-intercept* of the line; if b is zero, (2) goes through O, and conversely. The equation represents a line for every pair of real values of m and b; conversely,

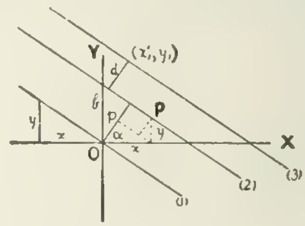

FIG. 6.

every line has a slope and a Y-intercept (positive or negative). Hence every equation of 1st degree in x and y represents a straight line, and conversely. Solving the equation $y=0$ of the X-axis and the equation of (2) as simultaneous, the intersection is found to be $\left(-\frac{b}{m}, 0\right)$, or $(a, 0)$, whence the equation of (2) may be written $\frac{x}{a}+\frac{y}{b}=1$, called the *intercept* or *symmetric form*, a being the X-intercept. The equation $y=mx+b$ is called the *slope form*. Other forms are readily obtainable, of which one of the most important is the so-called *standard* or *normal* form, $x\cos\alpha+y\sin\alpha-p=0$, readily deducible from the figure, where p is the length of the perpendicular (normal) from O to (2), α is the angle indicated, and P is any point of (2). The *general* equation

$$Ax+By+C=0$$

can be reduced to any of the foregoing forms. To reduce it to the normal form, it suffices to multiply by the *normalizing factor*, $1:\sqrt{A^2+B^2}$, yielding

$$\frac{Ax}{\sqrt{A^2+B^2}}+\frac{By}{\sqrt{}}+\frac{C}{\sqrt{}}=0,$$

where $\cos\alpha = A:\sqrt{\quad}$, $\sin\alpha = B:\sqrt{\quad}$, $p = -C:\sqrt{\quad}$, that sign before the radical being chosen which renders the constant (or absolute) term negative. A line is determined by yet other pairs of data, as by its slope m and a given point (x_1, y_1) or by two points (x_1, y_1), (x_2, y_2), and its equation assumes corresponding forms, which may be called respectively the *point-slope* form and the *two-point* form. The former plainly is $y - y_1 = m(x - x_1)$. The necessary and sufficient *condition* that this line shall pass through (x_2, y_2) is $y_2 - y_1 = m(x_2 - x_1)$. Combining the two equations by division, there results the two-point form, $(y - y_1):(y_2 - y_1) = (x - x_1):(x_2 - x_1)$, equation of the line fixed by the points (x_1, y_1), (x_2, y_2).

Distance from Point to Line.—The equation of any line (3), parallel to (2), Fig. 6, is $x\cos\alpha + y\sin\alpha - p' = 0$, where $p' = p + d$. The condition that (x', y') be on (3) is $x'\cos\alpha + y'\sin\alpha = p'$. Subtracting p from both members, we find $d = x'\cos\alpha + y'\sin\alpha - p$, distance from (x', y') to $x\cos\alpha + y\sin\alpha - p = 0$.

Angle between Lines.—Let ϕ be the angle between two lines whose slopes are m_1 and m_2. Then $\tan\phi = \pm(m_1 - m_2):(1 + m_1 m_2)$. If $\phi = 0$, then $\tan\phi = 0$, and $m_1 = m_2$, condition of parallelism. If $\phi = 90°$, then $\tan\phi = \infty$, and $1 + m_1 m_2 = 0$, whence $m_1 m_2 = -1$, condition of perpendicularity.

The Circle and Its Equation.—About any point (a, b) as center describe a circle of any radius r. Let $P(x, y)$ be any point of the circle. A glance at the figure shows that x and y are connected by the relation

$$(x-a)^2 + (y-b)^2 - r^2 = 0,$$

equation of the circle. By comparison with the equation $x^2 + y^2 + 2Ax + 2By + C = 0$, the

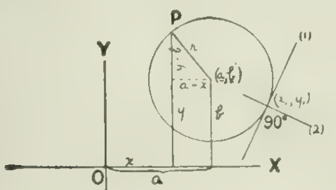

FIG. 7.

latter is found to represent a circle of center $(-A, -B)$, and radius $\sqrt{A^2 + B^2 - C}$. If the radicand be negative, the radius and hence the circle is imaginary. The tangent (1) to the circle at the point (x_1, y_1) is

$$(x_1 - a)(x - a) + (y_1 - b)(y - b) - r^2 = 0;$$

the normal (2) is

$$(y_1 - b)(x - x_1) - (x_1 - a)(y - y_1) = 0.$$

If the center be at the origin, the circle is $x^2 + y^2 = r^2$, the tangent at (x_1, y_1) is $x_1 x + y_1 y - r^2 = 0$, and the normal is $y_1 x - x_1 y = 0$. The line $y = mx + c$ is tangent to $x^2 + y^2 - r^2 = 0$ when and only when the distance from O to the line is r, *i.e.*, when $c = \pm r\sqrt{1 + m^2}$; hence $y = mx \pm r\sqrt{1 + m^2}$ is tangent to the circle and as m varies completely envelops the circle. Similarly it may be found that for every value of m the line $y - b = m(x - a) \pm r\sqrt{1 + m^2}$ is tangent to the circle of center (a, b) and radius r. This equation (in slope form) of the tangent is sometimes called the *magic* equation of the tangent. By transformation of coordinates or otherwise the polar equation of the circle of center (ρ', θ') and radius r may be found to be $\rho^2 - 2\rho'\rho\cos(\theta - \theta') + \rho'^2 - r^2 = 0$.

The Conic Sections: Ellipse, Parabola, Hyperbola.—The equation of the path, locus, or curve generated by a point (x, y) which so moves that the ratio of its distance from a fixed point (called the *focus*) to its distance from a fixed straight line (called the *directrix*) is a constant e (called the *eccentricity*) is of the form $Ax^2 + By^2 + Cxy + Dx + Ey + F = 0$; conversely, the locus of every equation of second degree is a curve of the kind in question. All such curves are called *conics* or *conic sections*, because any one of them is the intersection of a plane and a cone, where by cone is meant the surface that may be generated by a straight line revolving about a fixed point (vertex) and making a constant angle with a fixed line (axis) through the point; conversely, every such intersection is a conic, curve of second degree. The conics, of the very greatest importance alike in pure and in applied mathematics (cf. ASTRONOMY), were studied by the ancients (cf. APOLLONIUS), who conceived them as intersections of plane and cone. There are three species of conics, a conic being named *ellipse* (E), *parabola* (P), or *hyperbola* (H), according as the eccentricity $e <$, $=$, or > 1. The foregoing equation represents an E, a P, or an H, according as $4AB - C^2$ is *positive*, *zero*, or *negative*. Among the conics of any species are *degenerate* or *degraded* or so-called *improper* conics of that species. The degraded form of E is any pair of imaginary straight lines intersecting in a real point (center of the conic, vertex of the cone); any pair of parallel real straight lines is a degraded P; and any pair of non-parallel real lines is a degenerate H. By suitable transformations of coordinates the equation of any conic may be made to assume a simplest, named *standard*, form. The standard forms of the species are presented below.

Ellipse.—The standard form of the E is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, in which a is the half *major*, and b the half *minor*, *axis* of the E. The focus

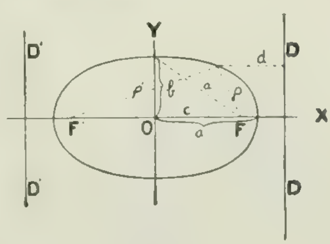

FIG. 8.

and directrix are respectively F and DD or F' and $D'D'$. The equations of the directrices are $x = \pm a:e$; $e = c:a$. The sum of the focal radii of any point of E is $\rho + \rho' = 2a$, a property often taken as definition of the E, instead of the relation $\rho = ed$. If $b = a$, the E is a circle;

hence the circle is an E of coincident foci and eccentricity zero. The area of E is πab.

Hyperbola. — The standard equation is $\frac{x^2}{a^2}-\frac{y^2}{b^2}=1$, where a is half of the *transverse*, and b is half of the *conjugate, axis*. The equation represents the curve composed of the two branches (1) and (2). For any point,

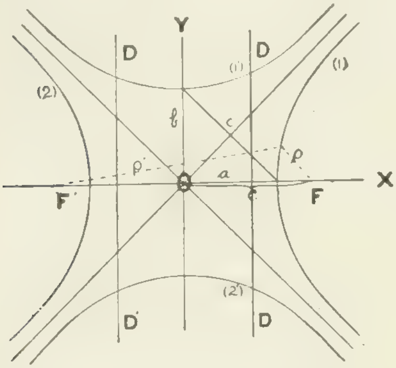

Fig. 9.

$\rho'-\rho=2a$, a defining property of the H. The H composed of (1′) and (2′) is called *conjugate* to the other one and has $\frac{x^2}{a^2}-\frac{y^2}{b^2}=-1$ for its equation. The two oblique lines through O *tangent* to both H's at ∞ are named *asymptotes* of the curves. The equations of the asymptotes are $y=\pm\frac{b}{a}x$. The corresponding lines of the E are imaginary, $y=\pm i\frac{b}{a}x$. If $a=b$, the H, $x^2-y^2=a^2$, is called equiaxial or equilateral or *rectangular*, its asymptotes being at right angles. It is related to the general H as the circle to the general E.

Parabola.—The standard equation is $y^2=4px$. The equation of the directrix is $x=-p$; the coordinates of the focus are $(p, 0)$; for any

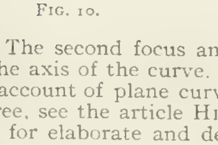

Fig. 10.

point $\rho=d$. The second focus and the center lie at ∞ on the axis of the curve.

For some account of plane curves of higher order or degree, see the article Higher Plane Curves, and for elaborate and detailed treatment of the analytical geometry of the plane, including exhaustive discussion of the conics, see works cited in bibliography below. We add here a note introducing the Cartesian geometry of

Space.

Coordinate Configurations. — Space is tri-dimensional in points, three independent data being necessary and sufficient to determine the position of a point. Of such data the simplest are the distances, Cartesian rectangular *coordinates*, x, y, z, of a point P from three fixed planes XOY, YOZ, ZOX, each perpendicular to the other two. These *coordinate planes* determine three lines, called *coordinate*

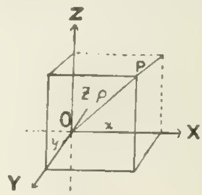

Fig. 11.

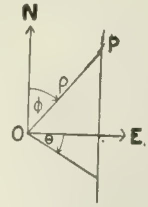

Fig. 12.

axes, having a common point O, the *origin*. Positive directions are indicated by the arrowheads. The polar coordinates of a point P, Fig. 12, are the radius vector ρ, and the vectorial angles θ and ϕ, reckoned respectively from the pole O and the *polar axes* OE and ON. If the pole coincide with the origin, and the polar axes with OX and OZ, then $x=\rho\cos\theta\sin\phi$, $y=\rho\sin\theta\sin\phi$, $z=\rho\cos\theta$, $\rho=\sqrt{x^2+y^2+z^2}$, $\tan\theta=y:x$, $\cos\phi=z:\rho$, formulæ of transformation from either system to the other. If α, β, γ are the direction angles (made respectively with OX, OY, OZ) of the radius vector ρ of any point P, Fig. 11, then $x=\rho\cos\alpha$, $y=\rho\cos\beta$, $z=\rho\cos\gamma$, and $1=\cos^2\alpha+\cos^2\beta+\cos^2\gamma$, sum of squares of *direction-cosines* of ρ. Any linear equation $Ax+By+Cz+D=0$ represents a plane. The symmetric equation of a plane is $\frac{x}{a}+\frac{y}{b}+\frac{c}{z}=1$, a, b, c being the axial intercepts extending from O to the plane. In normal form the equation of the plane is $x\cos\alpha+y\cos\beta+z\cos\gamma=p$, where p is the length, and $\cos\alpha$, $\cos\beta$, $\cos\gamma$ are the direction-cosines, of the perpendicular from O to the plane. To convert $Ax+By+Cz+D=0$ to the normal form it suffices to multiply it by the normalizing factor, $1:\sqrt{A^2+B^2+C^2}$, the new coefficients $A:\sqrt{}$, $B:\sqrt{}$, $C:\sqrt{}$, being $\cos\alpha$, $\cos\beta$, $\cos\gamma$, and $D:\sqrt{}$ being $-p$. The angle θ between two planes $Ax+By+Cz+D=0$ and $A'x+B'y+C'z+D'=0$ is determined by the relation

$$\cos\theta=(AA'+BB'+CC'):\sqrt{(A^2+B^2+C^2)(A'^2+B'^2+C'^2)},$$

whence the planes are parallel when and only when $A:A'=B:B'=C:C'$, and are perpendicular when and only when $AA'+BB'+CC'=0$. The equations of any two of the planes containing a line, *together* represent the line. Accordingly in space the line has *two* equations. Its simplest equations are those of any two of the three planes containing the line and being perpendicular respectively to the coordinate planes, as $x=mz+p$, $y=nz+q$. Such a pair are unsymmetric. Symmetric equations of the line directed by α, β, γ, and going through the point (x_1, y_1, z_1) are

$$(x-x_1):\cos\alpha=(y-y_1):\cos\beta=(z-z_1):\cos\gamma,$$

in number three of which but (any) two are independent. The angle θ between two lines whose direction-cosines are proportional to

L, M, N and L', M', N', respectively, is determined by the relation

$$\cos\theta = (LL' + MM' + NN') : \sqrt{(L^2+M^2+N^2)(L'^2+M'^2+N'^2)},$$

whence the lines are parallel if and only if $L:L' = M:M' = N:N'$, and are perpendicular if and only if $LL'+MM'+NN'=0$. The angle θ between a line of direction-cosines proportional to L, M, N and a plane

$$Ax+By+Cz+D=0$$

is given by the relation

$$\sin\theta = (AL+BM+CN) : \sqrt{(A^2+B^2+C^2)(L^2+M^2+N^2)},$$

whence the line and plane are parallel if and only if $AL+BM+CN=0$ and are perpendicular if and only if $A:L=B:M=C:N$. The necessary and sufficient condition that the line $x=m_1z+p_1$, $y=n_1z+q_1$, shall intersect the line $x=m_2z+p_2$, $y=n_2z+q_2$, is that $(m_1-m_2):(n_1-n_2) = (p_1-p_2):(q_1-q_2)$.

The literature of the analytical geometry of space, herewith barely introduced, is extensive. For some account of further developments of the subject, see the articles SURFACES, THEORY OF, and CURVES OF DOUBLE CURVATURE, THEORY OF, in this Encyclopedia. In the doctrine above introduced the point is employed as element. Some account of the theories that arise on choosing for element some other geometric entity, as the plane, the line, the sphere, etc., may be found in the articles, GEOMETRY, MODERN ANALYTICAL, and GEOMETRY, LINE, AND ALLIED THEORIES, in this work.

Bibliography.—College text-books of analytical geometry abound. One of the scientifically best American texts is W. B. Smith's 'Coordinate Geometry.' The most comprehensive English works are Salmon's 'Conic Sections' and 'Geometry of Three Dimensions' (both of which have been translated into French by O. Chemin, and supplemented and translated into German by Wilhelm Fiedler), and Frost's 'Solid Geometry.'

CASSIUS J. KEYSER,
Adrain Professor of Mathematics, Columbia University.

Geometry, Elementary. Geometry is the science of space. Its object is the study of the properties of forms (configurations, figures) of every conceivable kind. The subject is thus endless in two ways: in the first place, the number of configurations is infinite—this is so even if we restrict ourselves to curves and surfaces; in the second place, any one type of figure has an inexhaustible variety of properties.

Elementary geometry may be roughly described as the study of the simpler or more evident properties of the simpler configurations. Specifically, the title refers to the body of geometric truths incorporated by Euclid in his famous 'Elements.' The text-books on elementary geometry used throughout the civilized world for the last twenty centuries are in fact merely revisions of the 'Elements'; so that the subject itself is often referred to, especially in England, as the study of Euclid. The majority of the theorems refer to points, straight lines, and planes, with their combinations. Of curves, only the circle is considered, and of surfaces, those related to the circle (spherical, cylindrical, conical).

It is not the object of this article to give a résumé of the standard theorems of elementary geometry, but rather to indicate some of the more significant general features, especially in the light of the more recent developments.

LOGICAL FOUNDATIONS.

The most prominent aspect of elementary geometry is the logical aspect: a great number of propositions, termed theorems, are deduced from a comparatively few propositions assumed at the outset and termed axioms or postulates. In the ideal treatment of the subject, all the assumptions should be enumerated explicitly, so that, if the question is asked, «Are the theorems of geometry true,» the mathematician can answer correctly, «Yes, if my postulates are true.» As to whether the postulates are true, that is not a matter for the mathematician as such to consider, but rather comes within the province of the physicist, psychologist, or philosopher.

The ordinary course in geometry, modeled after Euclid, does not carry out this ideal. Assumptions are continually being made as they may be needed for the purpose of proof, in addition to those explicitly enunciated as axioms and postulates. For example, in the first proposition of Euclid, dealing with the construction of an equilateral triangle on a given segment AB, circles are drawn with centres A and B and common radius AB, and it is then assumed that these circles intersect. The only justification given is the diagram or the appeal to spatial intuition. Again, in dealing with the congruence of triangles, it is assumed that a triangle may be moved about without altering its sides or angles, though the stated axioms do not even mention displacement. In spite of himself, Euclid's treatment is (partly) physical or intuitional, instead of purely mathematical, that is, purely logical.

It is only within the last few years that the ideal has been (practically) attained; that is, a set of explicit assumptions (termed axioms or postulates indifferently) drawn up, from which the propositions of ordinary geometry follow by purely logical processes. Geometry becomes then a branch of pure mathematics. As Poincaré expresses it, in this ideal treatment «We might put the axioms into a reasoning apparatus like the logical machine of Stanley Jevons, and see all geometry come out of it.»

Many contributors have aided in this development, among whom may be mentioned Gauss, Lobachevsky, Pasch, Veronese, and especially Peano and his co-workers in symbolic logic, Pieri and Peano. The most elaborately worked out system is that of Hilbert (1900). We give a brief account of his axioms.

Geometry deals with three systems of objects or elements termed *points*, *lines* (used here in sense of straight lines), and *planes*, connected by certain relations expressed by the words *lying in*, *between*, etc. It is not necessary for the development of the subject that these words should suggest visual images; in fact the concrete nature of the elements and

relations is to be eliminated from the discussion. To emphasize this abstract aspect, it is convenient to use symbols, say capital letters for points, italics for lines, and Greek letters for planes. The axioms are arranged in five groups as follows:

I. *Axioms of Association or Connection.* — 1. Any two different points A, B determine a line a. (Such points are then said to lie on the line.)

2. Any two different points on a line determine that line.

3. In any line there are at least two points, and in a plane there are at least three points not on a line.

4. Any three non-collinear points A, B, C determine a plane α.

5. Three non-collinear points of a plane determine that plane.

6. If two points A, B of a line a are in a plane α, then every point of a is in α. (The line is then said to lie in the plane.)

7 Two planes α, β which have a point A in common have at least a second point B in common.

8. There exist at least four points not in one plane.

II. *Axioms of Order.*—These deal with the relation expressed by the term *between*.

1. If A, B, C are points of a line and B is between A and C, then B is between C and A.

2. If A and C are points of a line a, then there exists on a at least one point B between A and C, and at least one point D such that C is between A and D.

3. Of any three collinear points, one and only one is between the other two.

These three axioms deal with the line, while the fourth deals with the plane.

4. If A, B, C are any three non-collinear points, and a is a line in their plane passing through a point of the segment AB, but not through A or B or C, then a contains a point of either the segment AC or the segment BC.

III *Axioms of Congruence.*—The first five axioms of this group relate to congruent segments and congruent angles. For example, a segment AB is congruent to itself and to the reversed segment BA; and segments congruent to the same segments are congruent to each other. Finally, the sixth is a metrical axiom concerning triangles: if two sides and the included angle of one triangle are congruent respectively to two sides and the included angle of another triangle, then the remaining angles are also congruent.

The fact that the remaining sides are congruent is not included as a part of the axiom because it may be proved. The other cases of congruent triangles are theorems. In Euclid the above statement is a theorem, but this is possible, as already observed, merely on account of unstated assumptions relating to displacement. Euclid's axiom that all right angles are congruent, in Hilbert's system becomes a theorem.

IV. *The Axiom of Parallels*.—This contains only the so-called *Euclidean axiom*, in the form: Given a line a and a point A not on a, then in the plane α determined by a and α there is only one line through A which does not intersect a.

V. *Axioms of Continuity.*—The continuity notion is analyzed into two parts of which the first (1) is stated in the axiom of *Archimedes:* 1. On a straight line consider any two points A, B and a point A_1 between them; construct the points A_2, A_3, . . . , in order, so that A_1 is between A and A_2, A_2 between A_1 and A_3, etc., and so that the segments AA_1, A_1A_2, A_2A_3, . . . , are congruent; then among the points so constructed there exists a point A_n such that B is between A and A_n. That is, by repeatedly laying off a given segment however small any assigned point of the line will be passed after a finite number of steps.

This axiom is sufficient for the development of the usual theorems of geometry. However the space to which the theorems apply would not be continuous in ordinary sense. It would in fact contain only those points of the space considered in analytical geometry whose coordinates are rational or expressible by radicals of the second order. To identify with continuous space it is necessary to add a final axiom (2) relating to convergent point sets, or else the so-called axiom of completeness which states that the system of elements (points, lines, planes) cannot be enlarged by adjoining other elements in such a way that all the previous axioms are preserved.

The fact that this set of axioms is sufficient is shown by actually deducing the usual body of theorems. This is done in Hilbert's 'Grundlagen.' Diagrams are here used, it is true, but only for convenience; the proofs can be given without any reference to the diagrams. Often the deduction of those results which are evident to the intuition is long and complicated. This is the case, for example, in showing that a triangle (or any simple polygon) has the properties expressed by the terms inside and outside. It must be shown from the axioms that the given triangle brings about a division of the points in its plane into three classes, namely, points P, points I, and points O, such that any two I points or any two O points may be connected by a broken line not containing any P point, while any broken line from an I point to an O point necessarily contains P points. To the intuition, of course, the P points are the points on the perimeter of the triangle, the I points are those inside, and the P points are those outside.

In the development it is important to observe that some theorems depend upon only part of the axioms. Thus from group I alone it follows that two planes having a point in common necessarily have a line in common, and that a line and a point determine a plane. The property of triangles and polygons stated above follows from group I and II. The theory of proportion may be established without employing group V. The theorem that if two triangles in one plane have their sides respectively parallel, the lines joining corresponding vertices are either parallel or concurrent (a special case of *Desargues'* theorem), can be proved without using axiom III 6 if and only if the spatial axioms in addition to the plane axioms are employed.

An important result which has been obtained recently is that while the areas of plane polygons may be treated without appealing to the continuity axioms, this is not possible with the volumes of polyhedrons. The difference is observed in Euclid's proofs: the

proposition that triangles having the same base and altitude are equal in area is demonstrated by adding or taking away congruent parts from congruent figures, while the corresponding proposition concerning triangular pyramids is proved by the method of limits, or the equivalent method of exhaustion. That this difference in treatment is not avoidable was established by Dehn (1901), who showed that there exist polyhedrons of equal volumes which cannot be formed by the addition or subtraction of respectively congruent polyhedrons. In plane geometry this formation applies to any two polygons with the same area.

The most fundamental question concerning the set of axioms is that of *consistency*. In the development of geometry no contradiction has thus far presented itself; but will this always be the caes? Can it be shown that no inconsistency can ever arise? The only known method of answering this question depends upon establishing a correspondence between the geometrical elements and certain numerical entities, and showing that any inherent contradiction in geometry would involve contradictory relations among these entities. The question is thus transferred to the field of Arithmetic. Are the axioms of number (commutative, associative, distributive, etc.) inconsistent? No direct proof has yet been devised.

Another question to be considered is the independence of the axioms. If any one axiom can be deduced from the others, it may be omitted from the list and introduced as a theorem. It is therefore desirable that the axioms should express mutually independent statements. The standard method employed in proving the independence of an axiom or group of axioms consists in devising a set of objects of any kind which, when considered as elements, fulfill the relations expressed in remaining axioms, but for which the axiom or group in question is not satisfied. Thus the fact that the axiom of parallels (IV) cannot be deduced from the other axioms is shown by the non-Euclidean geometry of Lobachevsky. Similarly, the independence of axiom VI is proved by means of the non-Archimedean geometries of Veronese and Hilbert. Various apparently artificial systems have been devised in this connection, which, while not amenable to the intuition, are conceivable and mathematically true because based on assumptions which may be shown to be free from inconsistency.

The set of axioms presented above is of course not the only one which may serve as foundation for ordinary geometry. Thus the axiom of parallels may be replaced by the statement that the sum of the angles of a triangle is two right angles. In general the propositions of a given collection may be derived from various sets selected from the total collection. In the present case the possibilities are endless.

Geometry may also be founded on other primitive (undefined) concepts than those introduced above. Thus in the discussions inaugurated by Helmholtz and continued by Lie and Poincaré, the principal concept is that of transformation (displacement, rigid motion) and the axioms include the group property (the resultant of two displacements is itself a displacement). The straight line is then no longer, as in Hilbert's system, a primitive concept, but receives definition: if in a displacement two points are fixed, there are an infinite number of fixed points forming, by definition, a straight line (the axis of rotation).

In the usual intuitional treatment the concept of general surface is assumed as a starting-point and the plane is then defined as a surface such that if any two of its points are joined by a straight line, the latter lies entirely in the surface. This obviously states more than is required for the determination of the surface. To meet this objection the plane is sometimes defined as generated by drawing straight lines from a fixed point A to all the points of a straight line a. To obtain the entire plane it is necessary to add the line through A parallel to a. This definition is therefore unsatisfactory, because parallel lines require in their definition the previous definition of the plane. Peano has met the difficulty by this definition: Consider three fixed points A, B, C not in a straight line; take a fixed point D within the segment BC, and on the segment AD take a fixed point E; a plane is then generated by the lines (rays) from E to every point of the perimeter ABC. It may then be proved that a straight line connecting any two points of such a surface lies on the surface.

Problems and Constructions.

The only instruments whose use is implied in the postulates of elementary geometry are the ruler (straight-edge), for drawing straight lines, and the compass, for drawing circles. Only those problems are considered as coming within the domain of elementary geometry which can be solved by a finite number of operations with these instruments. Such constructions are termed *Euclidean*, or sometimes simply *geometric*. An example is the construction for bisecting an angle. With the vertex V as centre and any radius describe a circle cutting the sides of the angle in points A and B; with these points as centres and any (sufficiently large) radius describe circles intersecting in points C and D; the line joining C and D necessarily passes through V and bisects the given angle.

However, many problems arise which cannot be solved in this way. A well-known example is the problem of trisecting an angle. For centuries the Greek geometers and their followers sought for a solution; only within the present century has it been shown that such attempts must necessarily fail. The statement that the problem is impossible does not deny that lines trisecting the given angle exist, but means simply that such lines cannot be obtained by a construction employing a finite number of straight lines and circles.

No one has yet succeeded in demonstrating this impossibility by purely geometric means. The question arises naturally in elementary geometry, but apparently cannot be answered by elementary methods. We give now an outline of the algebraic method for deciding whether a given problem comes within the class of possible or the class of impossible problems.

Any line segment may be represented by a segment, namely, the ratio of the given seg-

ment to an assumed unit segment. Conversely, any number then represents a segment. Consider now the elementary operations of arithmetic or algebra in relation to geometric constructions.

If a and b denote given segments, or the corresponding numbers, the sum $a+b$ is constructed by transferring the segment b, by means of the compass, so that it is collinear and adjacent to a. The difference $a-b$ is also readily constructible.

The product $x=ab$ may be defined by the proportion $1:a=b:x$. The proper construction is then suggested by the theorem that a line parallel to the base of a triangle divides the sides proportionally. Draw any triangle with 1 and a as two of the sides; along the first side prolonged if necessary lay off segment b; from the terminal point draw a line parallel to the base of the triangle; this cuts off on the second side a segment equal to the required x. The quotient $y=a/b$ is obtained similarly from the proportion $b:1=a:y$. Hence all rational expressions, that is, expressions formed by a finite number of additions, subtractions, multiplications, and divisions are constructible.

Furthermore, extraction of square roots is possible. For $z=\sqrt{a}$ may be defined by $1:z=z:a$. Hence if on $1+a$ as diameter a semicircle is described, the perpendicular at the end of the unit segment is the required z. Therefore,

Theorem I.—Any expression involving only rational operations and the extraction of square roots can be constructed with ruler and compass.

Expressions which cannot be reduced to this form cannot be constructed. This we now prove in the form of the converse:

Theorem II.—Any segment which can be constructed with ruler and compass is expressible algebraically by rational operations and the extraction of square roots.

For any such construction consists in drawing a finite number of straight lines and circles and finding their intersections. Employing Cartesian coordinates (see GEOMETRY, CARTESIAN), the equation of a straight line is of the form $ax+by+c=0$, and that of a circle is of the form $x^2+y^2+ax+by+c=0$. The intersection of two straight lines leads to the solution of two equations of the first degree, which requires only rational operations. The intersections of a straight line and circle, or of two circles, depends on the solution of quadratic equations and leads to radicals of the second degree.

We proceed to apply these theorems to several examples.

Consider first the problem of bisecting an angle. The given angle θ and the required angle $\frac{\theta}{2}$ may be determined by their cosines.

Let $a=\cos\theta$ and $x=\cos\frac{\theta}{2}$ From trigonometry $\cos\theta=2\cos^2\frac{\theta}{2}-1$, that is, $2x^2-1=a$. Hence $x=\sqrt{\frac{1+a}{2}}$. Therefore, by Theorem I, the problem is elementary. The formula also indicates a definite method of construction.

In the *trisection* of a given angle we require the formula $\cos\theta=4\cos^3\frac{\theta}{3}-3\cos\frac{\theta}{3}$. Here $\cos\theta=a$ is known, and $\cos\frac{\theta}{3}=x$ is required. The equation of the problem is

$$4x^3-3x-a=0.$$

When solved by Cardan's formula this leads to cube roots. But before Theorem II can be applied it must be shown that no expression involving only square roots can satisfy the equation. This is true in the present case by the following general theorem taken from the theory of equations:

Theorem III.—An irreducible equation whose degree is not a power of two cannot have a root expressible by radicals of the second degree. (The term irreducible equation is here employed to describe an equation $f(x)=0$ with rational coefficients whose left member cannot be factored rationally.)

In general the algebraic questions which arise in this connection require for their complete discussion the powerful Galois Theory of Equations. See EQUATIONS, GALOIS' THEORY OF.

A second of the so-called famous problems of elementary geometry is the *Delian problem*, or the duplication of the cube. Given a cube with side a, to construct a cube with side x having double the volume. The equation of the problem is $x^3=2a^3$. Theorem III and then Theorem II apply. The corresponding problem concerning the square, leading to the equation $x^2=2a^2$, is easily solved: the side of the required square is simply the diagonal of the given square.

Regular Polygons.—The construction of a regular polygon of n sides is equivalent to the division of a given circumference into n equal arcs. The only cases treated by Greek geometers and the ordinary text-books are, for prime numbers, $n=3$ and $n=5$; from these constructions of the regular triangle and pentagon, combined with the construction for bisecting an angle, the constructions for the cases 2^κ, $3\cdot 2^\kappa$, $5\cdot 2^\kappa$, $3\cdot 5\cdot 2^\kappa$, where κ is any integer, are easily found.

No advance was made, that is, no new constructible polygons were discovered, until Gauss, about a century ago, applied the algebraic method. The equation of the problem may be put into the form

$$x^{n-1}+x^{n-2}+\ldots+x+1=0,$$

which is then termed the *cyclotomic equation*. When n is a prime number the equation is irreducible. Hence by Theorem III the construction is possible only when $n-1$ is a power of 2. That is, n must be of the form $2^\mu+1$. Prime numbers of this type are necessarily of the form $2^{2^\nu}+1$, and are known as *Fermat primes*. The values $\nu=0$ and $\nu=1$ give the familiar cases $n=3$ and $n=5$; the first new case, arising from $\nu=2$, is $n=17$. The construction for the regular polygon of 17 sides is complicated, but the steps are indicated definitely by the algebraic solution of the cyclotomic equation, which is in fact solvable by square roots.

The general result on regular polygons is as follows; The regular polygon of n sides

can be constructed with ruler and compass if, and only if, the prime factors of n are 2 repeated any number of times and distinct Fermat primes.

The first impossible cases are $n=7$ and $n=9$.

Quadrature of the Circle.—This most famous problem of geometry requires the construction of a square having the same area as a given circle. That this is impossible (that is, that the construction cannot be effected with the ruler and compass) was not definitely shown until 1882, although the failure of innumerable attempts had led many to suspect the true result. The *rectification* of the circle, that is, the construction of a straight line having the same length as a given circumference, is an equivalent problem, and hence also impossible. This is so on account of the theorem that the area of a circle equals one half the product and the radius into the circumference.

The ratio of the circumference to the diameter is the same for all circles: the constant thus arising has been generally denoted by the symbol π since the time of Euler. It was proved, quite simply, by Legendre that π is not rational (i.e., cannot be represented exactly by the ratio of any two integers, and hence, in particular, cannot be represented by a terminating decimal). The difficulty consists in showing that π is *transcendental*, that is, is not the root of any algebraic equation

$$a_0x^n + a_1x^{n-1} + \ldots + a_n = 0,$$

where n is a positive integer, and the coefficients are any integers. This was finally proved by Lindemann in 1882, after Hermite in 1873 had shown that e, the base of the Napierian system of logarithms, is transcendental. The two numbers are connected by the remarkable relation $e^{i\pi} = -1$, where i is the imaginary unit number $\sqrt{-1}$. Since π cannot satisfy any algebraic equation, it certainly cannot be expressed by square roots. Hence Theorem II proves the impossibility.

Approximate Constructions.—The problems considered cannot be solved exactly by ruler and compass, but they can be solved to any required degree of approximation. Thus a simple approximate solution of the rectification problem is the following: Let O be the centre and AB any diameter of the given circle. At the middle point E of AO construct a perpendicular cutting the circumference in C and D. On AB prolonged lay off $EF = CD$. Draw FD, and on this line lay off $FH = AB$. Then the segment HD is approximately one fourth the circumference. The error is less than one part in 5000.

Other Instruments.—The problems considered may be solved exactly if other instruments in addition to ruler and compass are allowed. Thus the trisection and duplication problems (like all problems depending on cubic and biquadratic equations) can be solved by the instruments for drawing parabolas or other conics, or by appropriate linkages. The quadrature of the circle, being a transcendental problem, cannot be effected by any instrument which draws algebraic curves. It can be solved by various transcendental curves (quadratrix, sinusoid, cycloid); or by the integraph (an instrument which draws the curve $y = \int f(x)dx$, where $y = f(x)$ is a given curve).

We consider now various restrictions which may be imposed on Euclidean constructions.

(1) *Ruler Constructions.*—Here only the straight-edge is allowed. For the possibility of such a construction it is necessary but not sufficient that the corresponding algebraic expression should be rational. If two parallel lines are given, then through a given point a line may be drawn parallel to given lines by a ruler construction. But this is not the case when a line is to be drawn through a given point parallel to a given line. The impossibility proof, based upon projection, may be carried out by pure geometry.

(2) *Masheroni Constructions.*—Here only the compass is allowed. A straight line is considered as known when two of its points are determined. Masheroni, in 1797, showed that all problems which can be solved by the ruler and compass can be solved by the compass alone.

(3) Poncelet and Steiner have shown that, if a single fixed circle with its centre is given, all elementary constructions may be carried out by means of the straight-edge. Again, if a ruler with parallel edges may be employed (it is then, for instance, possible to place the instrument so that each edge goes through an assigned point), all elementary problems may be solved without the compass.

(4) Hilbert considers constructions with the straight-edge and *sect-carrier*. The latter denotes a compass used not to draw circles, but merely to lay off a given segment on a given line. All such constructions can be carried out by the straight-edge and a movable unit sect. The test for deciding the possibility or impossibility of a problem in this sense is exceedingly complicated, depending on the higher theory of algebraic numbers.

Geometrography.—A problem of elementary geometry can usually be solved in a variety of ways by the ruler and compass. Thus for the Apollonian problem (to construct a circle touching three given circles) over one hundred distinct solutions have been worked out (Apollonius, Poncelet, Steiner, Lemoine, Study, etc.). How can we compare these as regards simplicity? It is necessary to adopt some standard or measure of simplicity. One method, for instance, would be to take the number of lines and circles as the measure of simplicity.

A more complete (but still somewhat artificial) discussion has been elaborated by E. Lemoine in his 'Geometrography.' Constructions are analyzed into the following elementary operations: Operation C_1 consists in placing one point of the compass on a given point in the plane of construction; including a given length between the points of the compass is then denoted by $2C_1$; placing a point of the compass on an undetermined point of a line is operation C_2; drawing a circle is C_3; making the edge of the ruler pass through an assigned point is operation R_1, and through two assigned points is $2R_1$; finally, drawing a straight line is operation R_2. Any construction may then be represented by a symbol $l_1R_1 + l_2R_2 + m_1C_1 + m_2C_2 + m_3C_3$, where the coefficients represent the numbers of elementary operations involved. The *simplicity* is measured by $l_1 + l_2 + m_1 + m_2 + m_3$, and the *exactness* by $l_1 + m_2 + m_3$ (the preparatory operations). The number of lines employed is given by l_2 and of circles by m_3.

In the case of the construction for the bisection of an angle explained above the symbol is $3C_1+3C_3+2R_1+R_2$. The construction which leads to the smallest possible value for the *simplicity* is termed the geometrographic solution. There may be more than one solution of this kind.

EDWARD KASNER,
Instructor in Mathematics, Columbia University.

Geometry, Line-, and Allied Theories.—For geometric purposes space may be conceived in an endless variety of ways (see CARTESIAN GEOMETRY), *i.e.*, as the manifold of all the geometric entities of *any* given kind contained in it. In particular, it may be viewed as the assemblage (manifold, aggregate, plenum) of its points or of its planes or of its lines. According as one or another of these views be adopted as fundamental, any configuration, as a curve or a surface, will present as fundamental the corresponding aspect, *i.e.*, it will appear as the *locus* (assemblage) of its points or as the *envelope* (assemblage) of its tangent planes or as the *envelope* (assemblage) of its tangent lines. These various views or aspects are not independent. Each involves the others, but they are not coordinate: one of them being assumed as fundamental or *primary*, the others appear as derived or *secondary*. Space accordingly admits of various geometric theories distinguished by and taking their names from their primary elements. Line-geometry contemplates space as primarily composed of lines, employs the line as fundamental element, and has for its subject-matter the relations and properties of line configurations. Thus the rôle of the right line in this doctrine is quite analogous to that of the point or the plane in the older geometries. The plane, too, has a line-geometry (see GEOMETRY, MODERN ANALYTICAL), but the line and the point theories of the plane, being analytically identical, are best treated simultaneously as dual aspects of a single doctrine.

The honor of having been the first to make formal and systematic use of the right line as primary element in the geometry of space belongs to Julius Plücker (1801–1868), whose 'Neue Geometrie des Raumes gegründet auf die Betrachtung der geraden Linie als Raumelement,' 1868–69, is the first great contribution to the subject. The idea of employing the line as space element had indeed occurred to him at a much earlier date. (Cf. his 'System der Geometrie des Raumes,' 1846.) His first memoir on the subject, entitled 'On a New Geometry of Space,' was published in English in 1865 and may be found in vol. 14 of 'The Proceedings of the Royal Society of London' and elsewhere. Certain important line systems, as congruences and complexes (names given by Plücker), had indeed been previously studied to some extent by others. The notion of congruences of lines naturally first presented itself in geometric researches in optics, and in fact the first appearance of the concept of the line complex seems to be that found in the 'Traité d'Optique' of the physicist, Étienne Louis Malus (1775–1812). The point-plane and line-line correlations or null-systems established by the linear complex were considered in 1827 by the Italian geometrician Giorgini (('Memorie dei XL.,' vol. 20), and in 1833 by Moebius in a memoir entitled 'Über eine besondere Art dualer Verhältnisse zwischen Figuren im Raume' ('Crelle's Journal,' vol. 9–10). Nevertheless the invention of the line geometry of space is, as said, to be properly ascribed to Plücker. His work in this field is the beginning of a great epoch in the science of analytical geometry. The undying influence of that work is due neither to its content nor, strictly speaking, to its method, important as these are. It is rather due to its spirit, which is the spirit of freedom, emancipating alike from traditional concepts and traditional modes of procedure. Since Plücker's time the science begun by him has been greatly refined and vastly extended, and out of it have come great and growing kindred doctrines, as the sphere and the circle geometries of space, and allied theories in spaces of higher dimensionality. The following paragraphs present a brief account of the elements of some of these theories, especially of line geometry, together with some indications of further developments and references to the corresponding literature.

Line Coordinates.—In Cartesian coordinates (see GEOMETRY, CARTESIAN) the line is determined by any pair of its projecting planes, *e.g.*, by the pair $x=rz+\rho$, $y=sz+\sigma$; conversely, any such pair determines a line. Accordingly the position of the line depends upon four independent quantities or *coordinates*, r, s, σ, ρ; the line has four degrees of freedom, space contains a fourfold infinity, ∞^4, of lines; in lines it is 4-dimensional: a being who thought in lines as «naturally» as man thinks in points would regard (our) space as having four instead of three dimensions. Linear transformation of Cartesian coordinates converts the line coordinates r, s, σ, ρ into the coordinates r', s', σ', ρ' (of the same line) where these are fractions whose terms are linear functions of r, s, σ, ρ, and $r\sigma-s\rho$; and, accordingly, an equation of degree n in r, s, σ, ρ is converted into one of degree $2n$ in those quantities. In order that the new and the old equations should be of the same degree in the old coordinates, Plücker introduced a fifth coordinate η, where $\eta=r\sigma-s\rho$. There are numerous other systems of line coordinates, and in his above-cited first paper Plücker himself presents no less than eight distinct systems. Of all the systems those that are *homogeneous* are at once the most artistic and convenient. These naturally present themselves as follows: If x_i and ξ_i $(i=1, 2, 3, 4)$ denote respectively the homogeneous coordinates (see GEOMETRY, MODERN ANALYTICAL) of a point and a plane referred to a fundamental tetraedron, then the equation $\xi_1x_1+\xi_2x_2+\xi_3x_3+\xi_4x_4=0$, or $\Sigma\xi_ix_i=0$, will

serve to represent the plane ξ_i (as locus of points) or the point x_i (as envelope of planes). It is at the same time the condition that the point x_i and the plane ξ_i shall be united in position, each containing the other. The line determined by two planes ξ_i and η_i is represented by the pair of equations $\Sigma\xi_i x_i=0$, $\Sigma\eta_i x_i=0$. It is equally determined by any two planes of the axal pencil $\Sigma(\xi_i+\lambda\eta_i)x_i=0$. Of these the simplest are the four of which each contains a vertex of the tetraedron of reference. Their equations are

$$\begin{aligned}
* \quad + q_{12}x_2 + q_{13}x_3 + q_{14}x_4 &= 0,\\
q_{21}x_1 + \quad * \quad + q_{23}x_3 + q_{24}x_4 &= 0,\\
q_{31}x_1 + q_{32}x_2 + \quad * \quad + q_{34}x_4 &= 0,\\
q_{41}x_1 + q_{42}x_2 + q_{43}x_3 + \quad * \quad &= 0,
\end{aligned}$$

where $\rho q_{jk}=\xi_j\eta_k-\xi_k\eta_j$, ρ being a proportionality factor; *e.g.*, $\rho q_{12}=\xi_1\eta_2-\xi_2\eta_1$. As $q_{jk}=-q_{jk}$, there are but six numerically distinct coefficients q. These are connected by the quadratic identity $q_{12}q_{34}+q_{13}q_{42}+q_{14}q_{23}=0$; as, moreover, only their ratios are essential, the six q's are equivalent to but four independents. Accordingly the q's may be, and for the sake of symmetry are, adopted as *six homogeneous coordinates of the line regarded as the axis* (*envelope*) *of a pencil of planes.*

The line has another aspect; it may be viewed as locus of its points, determined by any pair of them as x_i and y_i. So viewed, it is represented by the pair of point equations $\Sigma x_i\xi_i=0$, $\Sigma y_i\xi_i=0$. The line is equally determined by any two points of the range $\Sigma(x_i+\lambda y_i)\xi_i=0$ and in particular by any two of the four points in which the line pierces the faces (planes) of the fundamental tetraedron. Of these points the equations are

$$\begin{aligned}
* \quad + p_{12}\xi_2 + p_{13}\xi_3 + p_{14}\xi_4 &= 0,\\
p_{21}\xi_1 + \quad * \quad + p_{23}\xi_3 + p_{24}\xi_4 &= 0,\\
p_{31}\xi_1 + p_{32}\xi_2 + \quad * \quad + p_{34}\xi_4 &= 0,\\
p_{41}\xi_1 + p_{42}\xi_2 + p_{43}\xi_3 + \quad * \quad &= 0,
\end{aligned}$$

where $\sigma p_{kj}=x_jy_k-x_ky_j$. The six p's satisfy an identity like that of the q's, the ratios of the p's are alone important, and, again with a view to symmetry, the p's are chosen as the *six homogeneous coordinates of the line conceived as a locus* (*range*) *of points.*

It is readily found that the line p_{jk} and the line q_{jk} are one and the same when and only when $p_{12}:q_{34}=p_{13}:q_{42}=p_{14}:q_{23}=p_{34}:q_{12}=p_{42}:q_{13}=p_{23}:q_{14}$. Accordingly, disregarding both the locus and envelope aspects of the line, we may employ for its coordinates any six quantities r_{jk} which, ρ and σ being proportionality factors, satisfy the relations: $r_{12}=\rho q_{12}=\sigma p_{34}$, $r_{13}=\rho q_{13}=\sigma p_{42}$, $r_{14}=\rho q_{14}=\sigma p_{23}$, $r_{34}=\rho q_{34}=\sigma p_{12}$, $r_{42}=\rho q_{42}=\sigma p_{13}$, $r_{23}=\rho q_{23}=\sigma p_{14}$. The identity connecting the r's may be written (after Koenigs) $\omega(r)=2(r_{12}r_{34}+r_{13}r_{42}+r_{14}r_{23})=0$.

Passing from homogeneous to Cartesian point coordinates, *i.e.*, from a finite tetraedron to an infinite one having three of its faces mutually perpendicular and for the fourth the plane at ∞, there result the six homogeneous line coordinates employed by Plücker. The transition is effected by substituting x', y', z', 1 respectively for x_1, x_2, x_3, x_4, and x'', y'', z'', 1 for y_1, y_2, y_3, y_4; the Plücker coordinates accordingly are:

$p_{12}=x'y''-x''y'$, $p_{13}=x'z''-x''z'$, $p_{23}=y'z''-y''z'$, $p_{14}=x'-x''$, $p_{42}=y''-y'$, $p_{34}=z'-z''$.

If we replace x'', ... by $x'+dx'$, ..., *i.e.*, if we regard the line as determined by consecutive (neighboring, infinitely near) points, the Plücker coordinates assume the form adopted by Sophus Lie. The primes being omitted, the Lie line coordinates are: $p_{12}=xdy-ydx$, $p_{13}=xdz-zdx$, $p_{23}=ydz-zdy$, $p_{14}=-dx$, $p_{42}=dy$, $p_{34}=-dz$.

The general coordinates r_{jk} admit of further generalization. They may be replaced by linear functions of them; *i.e.*, if $r_{jk}=C_{jk\cdot 1}v_1+C_{jk\cdot 2}v_2+\dots+C_{jk\cdot 6}v_6$, where the determinant of the C's does not vanish, the six variables v_i may be employed as line coordinates. The v's satisfy a quadratic identity $\xi(v)=0$, into which $\omega(r)=0$ is converted by the foregoing transformation. A simple special case of this transformation yields an elegant system of line coordinates introduced by Felix Klein. Replacing the v's by x's, the special transformation is: $x_1=r_{12}+r_{34}$, $ix_2=r_{12}-r_{34}$; $x_3=r_{13}+r_{42}$, $ix_4=r_{13}-r_{42}$; $x_5=r_{14}+r_{23}$, $ix_6=r_{14}-r_{23}$; where $i=\sqrt{-1}$. The Kleinian line coordinates are x_j ($j=1,\dots,6$). The identity connecting them is $\Sigma x_j^2=0$.

Condition of Intersection of Lines.—The two lines may be conceived as loci, or as axes, or one as a locus and the other as an axis. In the first case, suppose the lines are determined respectively by the point pairs (x_i, y_i), (x'_i, y'_i). The lines p and p' will intersect when and only when the four points lie in a plane, for which the necessary and sufficient condition is

$$\begin{vmatrix} x_1 & x_2 & x_3 & x_4 \\ y_1 & y_2 & y_3 & y_4 \\ x_1' & x_2' & x_3' & x_4' \\ y_1' & y_2' & y_3' & y_4' \end{vmatrix}=0,$$

which on expansion yields $p_{12}p'_{34}+p_{13}p'_{42}+p_{14}p'_{23}+p_{34}p'_{12}+p_{42}p'_{13}+p_{23}p'_{14}=0$. Of this condition the first member is

$$\frac{1}{2}\left[\frac{\partial\omega(p)}{\partial p_{12}}p'_{12}+\dots+\frac{\partial\omega(p)}{\partial p_{42}}p'_{42}\right]$$
$$\equiv\frac{1}{2}\left[\frac{\partial\omega(p')}{\partial p'_{12}}p_{12}+\dots+\frac{\partial\omega(p')}{\partial p'_{42}}p_{42}\right].$$

Denoting this *polar* form by $\omega(p, p')$, the condition that the two lines (loci, point ranges) p and p' shall have a common point is $\omega(p,p')=0$. In like manner, the condition that the lines (envelopes, axal pencils of planes) q and q' shall have a common plane is $\omega(q,q')=0$. If one of the lines be regarded as a locus, the other as an envelope, the condition of intersection is $\Sigma p_{jk}q'_{jk}=0$ or $\Sigma q_{jk}p'_{jk}=0$. Disregarding the aspects of the lines r and r', the condition is $\omega(r,r')=0$. The preceding transformation from r's to v's converts $\omega(r,r')$ into $\xi(v,v')$, where $2\xi(v,v')=\frac{\partial\xi}{\partial v_1}v_1'+\dots+\frac{\partial\xi}{\partial v_6}v_6'$. Hence the condition that the lines v, v' shall intersect is $\xi(v,v')=0$. In Klein coordinates, the condition for the intersection of the lines x and x' is $\Sigma x_jx_j'=0$ ($j=1,\dots 6$).

Pencils and Hyperpencils.—Let v' and v'' be any two intersecting lines. These determine a flat pencil, *viz.*, that whose vertex is the common point of v' and v'' and whose lines

lie in the plane of v' and v''. All and only the coordinates of the lines of the pencil are given by the formula $v_i = \lambda v_i' + \mu v_i''$. For, first, $\xi(v) = \xi(v')\lambda^2 + 2\xi(v', v'')\lambda\mu + \xi(v'')\mu^2$, and, by hypothesis, $\xi(v') = 0$, $\xi(v'') = 0$, $\xi(v', v'') = 0$; hence $\xi(v) = 0$, and v_i represents a line for all values of the parameters λ and μ. Secondly, if v_i''' be *any* line cutting v' and v'', $\xi(v', v''') = 0$, $\xi(v'', v''') = 0$; hence $\xi(v, v''') = 0$, for $\xi(v, v''') = \lambda\xi(v', v''') + \mu\xi(v'', v''')$; therefore the lines v_i belong to the pencil. Thirdly, these are *all* of the lines of the pencil, for it is easily proved that the ratio, $\lambda:\mu$, can be determined so that the corresponding v_i shall cut *any* given line not contained in the plane of the pencil,

Koenigs has suggested the name hyperpencil (*hyperfaisceau*) to denote alike the totality of lines of a plane and the totality (sheaf, bundle) of lines through a point. A hyperpencil is determined by any three lines (not in a same pencil) of which each intersects the other two. If three such lines be v_i', v_i'', v_i''', then all and only the coordinates of the hyperpencil are given by the formula $v_i = \lambda v_i' + \mu v_i'' + \nu v_i'''$, λ, μ, ν being parameters. The hyperpencil will be a sheaf or a plane of lines according as the given lines determine but one point or three points.

Line Systems in General.—Just as, for example, in ordinary analytical geometry, we study systems (loci) of points represented by equations in point coordinates, so in the present subject we are concerned with line systems represented by equations in line coordinates. The line, we have seen, depends on four independent variables, coordinates, or *parameters.* The totality of lines in space may be called the 4-parameter system; it contains ∞^4 lines, a line in it has four degrees of freedom, one degree for each of the free (unconditioned) parameters or coordinates. One condition on the four parameters renders them equivalent to but three independent ones; hence the lines represented by one equation constitute a 3-parameter system, called by Plücker a line *complex.* A complex contains ∞^3 lines, a line in a complex has but three degrees of freedom. A 2-parameter system or *congruence* (Plücker), containing ∞^2 lines, allowing the line two degrees of freedom, is defined by a pair of equations. A triplet of equations represents a 1-parameter system, a ruled surface, or, better, a *line series* (*Série réglée*, Koenigs); it contains ∞^1 lines; in such a system the line has but one degree of freedom. Finally, a 0-parameter system, defined by four simultaneous equations, contains but a *finite* number of lines. In order, then, that five or more equations should represent a common system of lines, it is necessary that their coefficients satisfy some condition or conditions.

The Linear Complex.—The complex defined by an equation of degree n is said to be of nth degree. If $n = 1$, the complex is called *linear.* The general equation of the linear complex is $c_1v_1 + c_2v_2 + \ldots + c_6v_6 = 0$, or, briefly, $\Sigma c_j v_j = 0$, where $\xi(v) = 0$. How are the lines distributed? Let $v_i = \lambda v_i' + \mu v_i'' + \nu v_i'''$ be an arbitrary hyperpencil. In order that a line of the hyperpencil shall belong to the complex, it is necessary and sufficient that $\Sigma(\lambda v_i' + \mu v_i'' + \nu v_i''') = 0$, a single linear condition on the (two independent) ratios $\lambda:\mu:\nu$. Hence a single infinity of the lines of the hyperpencil belong to the complex. For if $u_i' = \lambda_1 v_i + \mu_1 v_i'' + \nu_1 v_i'''$ and $u_i'' = \lambda_2 v_i'' + \mu_2 v_i'' + \nu_2 v_i'''$ be any two of them, then plainly all lines of the pencil (u', u'') belong to the complex. On the other hand, no other line u''' does so belong, for, if it did, then every pencil determined by u''' and the lines of (u', u''), *i.e.*, all lines of the hyperpencil, would belong to the complex. Hence the proposition: *The lines of a linear complex are so distributed that every hyperpencil in space contains a pencil of lines (and no other line) belonging to the complex.* These pencils are called the pencils of the complex. The proposition admits of various equivalent statements of which one of the most illuminating is: *Given a linear complex, each point of space is the vertex of a pencil of lines of the complex and contains no other line of it; in each plane there is a pencil of lines (but no other line) of the complex.* In the former case the plane containing the pencil of the point is called the *polar* (plane) of the point; in the latter, the vertex of the pencil in the plane is called the *pole* (point) of the plane. Thus a linear complex serves to pair the points and planes of space as poles and polars, any pole and its polar being united in position. If a point P and a plane π be united in position, the pole P' of π and the polar π' of P are also united. Not only, however, are points and planes paired, but lines are paired with lines. The line common to two poles corresponds to the line common to their polars. Two such corresponding lines are called *conjugates* with respect to the complex. To a range of points (poles) corresponds an axal pencil of planes (polars), the base of the range and the axis of the pencil being conjugate lines. A line cutting two conjugates belongs to the complex, and all lines of the complex that cut a given line cut its conjugate also. If two lines intersect, so do their conjugates. Every line of the complex is its own conjugate, self-conjugate, and conversely. If a point moves along a line of the complex, the polar plane turns about the same line. This is a special case of the proposition that if a point glides along any line, the polar plane rotates about the conjugate line. Hence if P_1, P_2, P_3, P_4 be any four positions of the moving point and if π_1, π_2, π_3, π_4 are the corresponding planes, then the anharmonic ratios are equal, *i.e.*, $(P_1P_2P_3P_4) = (\pi_1\pi_2\pi_3\pi_4)$. In general: if C denote any configuration of points, lines, and planes, the polars, conjugates, and poles (with respect to a given complex) constitute a configuration C'. C and C' are called *reciprocal* configurations. The points, lines, and planes of either correspond uniquely and respectively to the planes, lines, and points of the other. In particular, if C is a polyedron, so is C'. The edges of either are conjugates of the edges of the other; the vertices and faces of either are respectively the poles and polars of the faces and vertices of the other. The vertices of either lie in the (polar) faces of the other.

Invariant of Complex, Special Complex, Directrix.—The condition,

$$2\xi(v, v') \equiv \frac{\partial\xi}{\partial v_1'}v_1 + \ldots + \frac{\partial\xi}{\partial v_6'}v_6 = 0,$$

that the line v shall intersect the line v', represents a *special* complex, viz., that of which all the lines cut a given line v', called

the *directrix* of the complex. The complex $\Sigma c_j v_j = 0$ is, then, special when and only when $\frac{\partial\xi}{\partial v_1'}:\frac{\partial\xi}{\partial v_2'}:\ldots:\frac{\partial\xi}{\partial v_6'}=c_1:c_2:\ldots:c_6$. These equations yield the values of (the ratios of) the v_j' in terms of the c_j. Substituting those values in $\xi(v')$, there results a homogeneous quadratic $\Omega(c)$, so that $\xi(v')=\Omega(c)$. Hence $\Omega(c)=0$ when and only when $\xi(v')=0$; hence the necessary and sufficient condition that $\Sigma c_j v_j = 0$ shall represent a special complex is that $\Omega(c)=0$. In such case the coordinates of the directrix are the coefficients c_j. The expression $\Omega(c)$ has been named by Klein the *invariant of the complex* $\Sigma c_j v_j = 0$. The complex is, therefore, special or non-special according as its invariant vanishes or does not. If $\xi(v)$ be reduced to the Plücker type $\omega(v) = 2(v_1v_4+v_2v_5+v_3v_6)$, the invariant assumes the form $\Omega(c)=2(c_1c_4+c_2c_5+c_3c_6)$. In case the above-mentioned Klein coordinates are employed, the form of the invariant is $-\Omega(c)=\Sigma c^2_j$ $(j=1, \ldots, 6)$.

Pencil of Complexes, and Line Congruence.—The system of lines *common* to two complexes is named line *congruence*. It is plain that the lines of the congruence determined by two complexes $\Sigma c_j v_j = 0$ and $\Sigma c_j' v_j = 0$ are common to the complexes of the pencil $\lambda\Sigma c_j v_j + \mu\Sigma c_j' v_j = \Sigma(\lambda c_j + \mu c_j')v_j = 0$ of complexes and that the congruence is equally determined by any two complexes of the pencil. Does the pencil include special complexes? If so, how many? The condition, $\Omega(\lambda c+\mu c')=0$, for special complexes, is quadratic in the ratio $\lambda:\mu$ of the parameters, and hence yields two values for that ratio, which may be real and distinct, real and equal, or imaginary. Accordingly, every pencil of complexes contains two and but two special complexes, real and distinct, coincident, or imaginary. The directrices of the special complexes are cut by all and only the lines of the congruence and are called the *directrices of the congruence*. Conversely, the assemblage of lines that intersect two given lines is a congruence. Hence a congruence is often defined to be the totality of lines intersecting two fixed lines. The directrices of a congruence are conjugate lines with respect to every complex of the corresponding pencil of complexes. In case the discriminant of the foregoing quadratic is zero, the directrices coincide. The (double) directrix is a line of the congruence. That discriminant is called the *invariant of the congruence*. The vanishing of the invariant signifies coincidence of the two special complexes and of their directrices. It may happen that the quadratic is identically zero. Then all complexes of the pencil are special, and the directrices constitute a pencil of lines.

Angle of Complexes; Involution.—Let a, b, c, d be any four values of the parameter $\lambda:\mu$ of the above pencil of complexes. The anharmonic ratio $(abcd)$ may be called the anharmonic ratio of the four corresponding complexes. If l be a line of the congruence, π a plane of l, and P_1, P_2, P_3, P_4 be the poles of π as to the complexes a, b, c, d respectively, then the anharmonic ratio $(P_1P_2P_3P_4)=(abcd)$. Also, if π_1, π_2, π_3, π_4 are the polar planes of a point P of l with respect to the four complexes, then $(\pi_1\pi_2\pi_3\pi_4)=(abcd)$. Hence $(\pi_1\pi_2\pi_3\pi_4)=(P_1P_2P_3P_4)$, and these equal ratios remain *constant* as π rotates about (P glides along) l and also as l varies its position in the congruence. We may suppose that b and d correspond to the *special* complexes of the pencil, and denote by F and F' the points common to l and the directrices, and by ϕ and ϕ' the planes determined by l and the directrices. Then $(P_1FP_2F')=(abcd)=(\pi_1\phi\pi_2\phi')$. Denote this anharmonic ratio by r. The corresponding angle, $A=(\log r):2\sqrt{-1}$, has been named by Klein the *angle of the complexes* a and c. If a and b be so taken (and that is possible) that $A=90°$, whence $r=-1$, then the two corresponding complexes are said to be *orthogonal* or *in involution*. The geometric significance of this relationship is that, when and only when it subsists between two complexes, each contains the conjugates of its lines with respect to the other. This subject of involution is intimately connected with the general doctrine of linear systems of linear complexes, but it cannot be further pursued here.

Hyperpencil of Complexes.—Such we may call the system $\Sigma(\lambda c_j+\mu c_j'+\nu c_j'')v_j=0$ determined by three independent complexes. $\Sigma c_j v_j=0$, $\Sigma c_j' v_j=0$, $\Sigma c_j'' v_j=0$. The name, system of three terms, is often employed instead of hyperpencil. The ∞^1 lines common to the three fundamental complexes are obviously common to all complexes of the hyperpencil. They constitute a ruled surface of second order. That the surface is of second order appears from the fact that the number of points in which it is pierced by a line u_j, *i.e.*, the number of solutions of the equations $\Sigma c_j v_j=\Sigma c_j' v_j=\Sigma c_j'' v_j=\xi(v)=\xi(v, u)$, is two. The surface is in general an *hyperboloid of one sheet;* in special case, a *hyperbolic paraboloid*. The lines constitute, however, but one system of generators. What of the other system? To answer, observe that the condition, $\Omega(\lambda c+\mu c'+\nu c'')=0$, that the hyperpencil shall contain special complexes, yields ∞^1 pairs of values of the (two independent) ratios $\lambda:\mu:\nu$. Hence the hyperpencil includes ∞^1 special complexes. The directrices of these constitute the second system of generators. These last are not lines common to the hyperpencil, on which account it seems better (after Koenigs) to call the lines common to the hyperpencil not a ruled surface, but a demi-quadric or series of lines.)

Complex of Higher Degree.—An equation $f_n(v)=0$ of degree n in line coordinates v_j defines a complex of degree n. Any line-pencil of space contains n lines of such a complex, so that the degree of a complex may be geometrically defined to be the number of lines common to the complex and an arbitrary pencil. The lines common to a complex of nth degree and a hyperpencil constitute a *cone* of *order* n if the hyperpencil is a *sheaf*, and envelope a plane *curve* of *class* n if the hyperpencil is a plane of lines. The cone is called *cone of the complex;* and the curve, *curve of the complex*. Every point of space is the vertex of such a cone, and every plane contains such a curve. As above seen, if $n=1$, the cone degenerates into a plane (pencil of lines) and the curve

degrades into a point (pencil of lines enveloping it). The 'Neue Geometrie' of Plücker is chiefly devoted to the *quadratic* complex, $n=2$, and many of its cardinal properties are there discovered. For the literature of the subject, including the general doctrine of complexes, the reader is referred to the works above cited and to the bibliography below. We give next a very brief account of certain closely

Allied Theories

the study of whose connections and general comparative anatomy is one of the most instructive and fascinating chapters in the development of modern geometry.

Plane Geometry of the Point in Four-space.—Space that is 4-dimensional in points is also 4-dimensional in *lineoids* (ordinary 3-dimensional spaces). It is 6-dimensional in lines and also in planes. Hence in 4-space the *point* and the *lineoid* are *dual* (reciprocal) elements, and so are the *plane* and the *line*. The lineoid contains ∞^4 lines; the point, ∞^4 planes. The lineoid contains ∞^3 points and as many planes; the point contains ∞^3 lineoids and as many lines. Hence in 4-space, the point, plane, and line geometries of the lineoid are respectively dual to the lineoid, line, and plane theories of the point. Between any two of these pairs of reciprocal geometries there is a fact-to-fact correspondence, and the algebras of any such pair are identical. The emphasis here falls upon the fact that the line geometry of the lineoid (*i.e.*, ordinary line geometry) is precisely the same analytically as the geometry of the 4-space point regarded as the assemblage of its (generating) planes. For an introductory detailed account of the elements of the latter theory, and of the mentioned parallelism, see 'The Plane Geometry of the Point in Point-space of Four Dimensions' ('American Jour. of Math.,' vol. 25).

Geometry of (Ordinary) Space in Pentaspherical Coordinates.—The square of the tangent-distance from a point to a sphere is named the *power of the point with respect to the sphere.* Denote by x_k $(k=1, \ldots, 5)$ the powers of a point with respect to five fixed mutually orthogonal spheres. The x_k satisfy the identity $\Sigma x_k^2=0$. To any set of values of their ratios there corresponds a definite point and conversely. The quantities λx_k are called *pentaspherical point coordinates.* Their discovery and introduction into geometry are mainly ascribable to Gaston Darboux (cf. his memoir 'Sur une class remarquable de courbes et de surfaces algébriques,' 1873), but in part also to Felix Klein and Sophus Lie (cf. 'Mathematische Annalen,' vol. 5). In these coordinates the equation of a sphere is linear, *viz.*, $\Sigma m_k x_k=0$ $(k=1, \ldots, 5)$; conversely, every such equation represents a sphere. The radius is $\rho=(\sqrt{\Sigma m_k^2}):\Sigma(m_k \div R_k)$, where the R_k are the radii of the fundamental spheres. Certain analytic correspondences between line geometry (in Klein coordinates) and point geometry in pentaspherical point coordinates are immediately obvious. For example: in the former $\Sigma x_j^2=0$ $(j=1, \ldots, 6)$ is the identity satisfied by the line coordinates x_j; in the latter, $\Sigma x_k^2=0$ $(k=1, \ldots, 5)$ is the identity connecting the pentaspherical point coordinates; in the former, $\Sigma m_j x_j=0$ represents a linear complex; in the latter, $\Sigma m_k x_k=0$ represents a sphere; in the former, $\Sigma m_j^2=0$ means that the complex is special; in the latter, $\Sigma m_k^2=0$ signifies that the sphere is a point; and so on and on.

Sphere Geometry of Space.—In this doctrine, due to Sophus Lie, the sphere is taken as primary element. To pick out a sphere from among all the spheres of space, it is necessary and sufficient to know four independent things about it, as the (three) coordinates of its center and the length of its radius. Hence the sphere, like the line, has four independent coordinates, it has four degrees of freedom, and sphere geometry, like line geometry, is 4-dimensional. We have seen that every equation $\Sigma m_k x_k=0$ in pentaspherical point coordinates x_k represents a sphere, and conversely; hence the five coefficients m_k may be taken as *homogeneous sphere coordinates*, their ratios being equivalent to four *independents.* The system may be rendered homologous to that of the six line coordinates by introducing a sixth sphere coordinate m_6 by the definition, $im_6 \equiv \sqrt{\Sigma m_k^2}$, where $i=\sqrt{-1}$ and $(k=1, \ldots, 5)$. The *six* homogeneous, sphere coordinates m_j $(j=1, \ldots, 6)$ satisfy the quadratic identity $\Sigma m_j^2=0$, identical in form with that connecting the Klein line coordinates. The condition that the *spheres* m and m' shall be *tangent* is $\Sigma m_j m_j'=0$, which is precisely like the condition, $\Sigma x_j x_j'=0$, that the *lines* x and x' shall *intersect*, a most interesting and fruitful principle of correspondence discovered by Lie in his brilliant memoir, 'Über Complexe, in besondere Linien- und Kugel-Complexe, mit Anwendung auf die Theorie partieller Differentialgleichungen' ('Mathematische Annalen,' vol. 5, 1871).

Circle Geometry of Space.—In this beautiful and growing theory, principally due to the French mathematicians E. Cosserat, C. Stéphanos, and G. Koenigs, the circle is employed as primary or generating element of space. In this element, space is 6-dimensional, like point 4-space in lines or planes. A circle is determined as the intersection of two spheres, as $\Sigma m_j x_j=0$, $\Sigma m_j' x_j=0$ $(j=1, \ldots, 5)$. It is equally determined by any two spheres of the pencil or range, $\Sigma(m_j+\lambda m_j')x_j=0$, of spheres containing it, and, in particular, by any two of the included five of which each is orthogonal to one of the fundamental spheres. The equations of those special spheres correspond to the five λ-values that render the coefficients $m_j+\lambda m_j'=0$ in succession. For the sake of symmetry, the *ten* coefficients $p_{ik}=(m_k'-m_k m_i'$ are taken as homogeneous coordinates of the circle. That the ten are equivalent to the necessary and sufficient number *six* of independents is seen in the facts that only their ratios are essential and that they satisfy five (equivalent to three independent) quadratic identities of the form $\omega_\alpha(p)=2(p_{\beta\gamma}p_{\delta\epsilon}+p_{\beta\delta}p_{\epsilon\gamma}+p_{\beta\epsilon}p_{\gamma\delta})=0$. The circle geometry of space is not parallel to the line geometry of ordinary space, but it is parallel, in a fact-to-fact fashion, to the line and the plane geometries of point 4-space.

Theory of Circles Orthogonal to Sphere.—Two spheres m_k and m_k' $(k=1, \ldots, 5)$ are *orthogonal* when and only when $\Sigma m_k m_k'=0$; hence there are ∞^3 spheres orthogonal to a given sphere. A *circle* is *orthogonal* to a *sphere* when and only when any two (and hence all) of its

generating spheres are orthogonal to the sphere. There are, accordingly, ∞^4 circles orthogonal to a given sphere. A one-to-one correlation subsists between such circles and the lines of space. If, in the assemblage of spheres orthogonal to a given sphere, four mutually orthogonal spheres be taken as fundamental or coordinate spheres, any equation $\Sigma m_k x_k = 0$ $(k = 1, \ldots, 4)$ will represent a sphere of the assemblage, and conversely. Hence a pair of such equations will define a circle orthogonal to the fixed sphere, and conversely. It is immediately plain that the coordinates of the circle regarded as element of the assemblage of circles orthogonal to a given sphere are analytically precisely the same as the line coordinates of space. Hence the geometry of such a circle assemblage is analytically identical with line geometry. The first chapters of such a circle geometry are found in the doctor's dissertation (at Columbia University, 1904), 'The Geometry of Circles Orthogonal to a Given Sphere,' by Mr. C. S. Forbes.

Bibliography.—The literature of line geometry and allied theories is extensive and is rapidly increasing. In addition to the foregoing citations, may be mentioned the following works, which together with further citations contained in them constitute a complete bibliography of the subject: Cayley, 'On the Six Coordinates of a Line' (Collected Papers, vol. 7); Klein, 'Einleitung in die höhere Geometrie' and various memoirs by him in vol. 5 and subsequent volumes of *Mathematische Annalen;* Koenigs, 'La géométrie réglée et ses applications' (*Annales de la Faculté des Sciences de Toulouse*, vols. 3 *et seq.*); Cosserat, 'Sur le cercle considéré comme élément générateur de l'espace' (see preceding reference); Loria, 'Il passato ed il presente delle principali teorie geometriche'; E. Pascal, 'Repertorio die mathematiche superiori'; Sturm, 'Die Gebilde ersten und zweiten Grades der Liniengeometrie,' a synthetic treatise; Pasch, 'Zur Theorie der linearen Complexe' (Crelle's Journal, vol. 75); Study, 'Geometrie der Dynamen'; Jessop, 'Treatise on the Line Complex'; 'Encyklopädie der Mathematischen Wissenschaften,' vol. 3.

CASSIUS J. KEYSER,
Adrain Professor of Mathematics, Columbia University.

Geometry, Modern Analytical. No preliminary statement of the significance of this title could be quite satisfactory to any, much less to all. An adequate sense of its meaning can be gained only by study of the subject itself; and in this case, as in that of most other doctrines, it is better for the reader to end, than for the writer to begin, by an attempt at definition. Logically and historically modern analytical geometry is the outgrowth of Cartesian geometry (q.v.). The former, while in a sense it includes the latter as a special case, avails itself of many principles, processes, and points of view unknown to the older doctrine. It is the aim of this article to give a brief account of some of the modern notions and methods, with particular reference to the geometry of the plane. For further information the reader may consult the articles: GEOMETRY, CARTESIAN; CURVES, HIGHER PLANE; LINE GEOMETRY AND ALLIED THEORIES; CURVES OF DOUBLE CURVATURE, THEORY OF; SURFACES, THEORY OF; HYPERSPACES. As to related matter of pure geometry, see the articles: GEOMETRY, ELEMENTARY PURE; GEOMETRY, PURE PROJECTIVE; and GEOMETRY, NON-EUCLIDEAN. In the following, acquaintance with the elements of ordinary (Cartesian) geometry will be presupposed.

One-dimensional Spaces: Range and Pencil; Elements at Infinity.—Any geometric entity in a given space may be taken as generating element of the space, which is then regarded as the assemblage of all the elements of the chosen kind. A space being assumed, its dimensionality depends upon the choice of generating element and is the number of independent parameters, or coordinates, necessary for the determination of the element. This is what is meant, to take the most familiar examples, by saying that any surface, say a plane, is two-dimensional, and that ordinary space is three-dimensional, in points. Any space being assumed, it is always possible to select as element an infinity of different kinds of entities for any one (kind) of which the space shall have a prescribed dimensionality k. Thus the plane is two-dimensional in lines (see below), its dimensionality is 3 in circles, 4 in parabolas, 5 in conics, ..., while the dimensionality of ordinary space is 3 in planes, 4 in lines or in spheres (see LINE GEOMETRY), 6 in circles, etc. A plane curve may in general be conceived either as a *locus*, assemblage of its *points*, or as an *envelope*, assemblage of its (tangent) *lines*. In either view the curve appears as a *one*-dimensional space, of points in the former view, of lines in the latter. Of such one-fold spaces, the simplest, and hence in a sense the most important, varieties are the *range* and the *pencil*, the former being the straight line regarded as the locus or assemblage of its points, and the latter being the point regarded as the envelope or assemblage of its lines (the lines through it). Commonly the line is called the *base* of its range, and the point is called the *vertex* of its pencil. In passing it may be pointed out that if a *pair* or *triplet*, ... of points (lines) be taken as element of the line (point), the line (point) appears as a space of 2, or 3, ... dimensions in such pairs, triplets, ...

Let V and b respectively be any pencil and range. The plane being supposed Euclidean in respect to parallels (see NON-EUCLIDEAN GEOMETRY), V contains a single line parallel

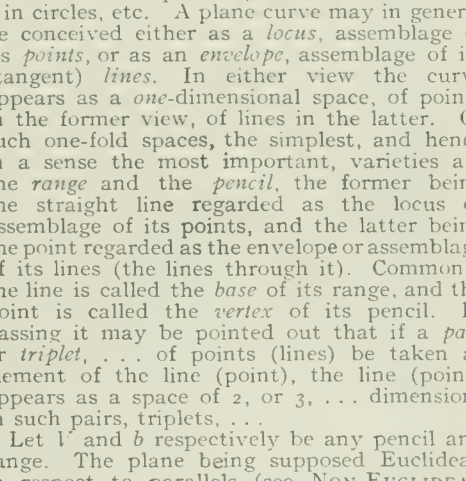

FIG. 1.

to b. Plainly, through any (finite) point of b there passes one and but one line of V: and, conversely, every line of V, except the mentioned parallel, passes through a (finite) point of b. In order to avoid the exception

and render the one-to-one correspondence complete, a convention is made, namely, that every range shall be regarded as having one and but one *infinitely distant* point P_∞, called the *infinite point* of the range, and that the infinite point of any range is identical with that of any parallel range. Accordingly any infinite point of the plane is the vertex of a pencil of parallel lines, and the system of lines parallel to a given one constitute a pencil vertexed at ∞. The notion of parallel lines meeting at ∞ had occurred to Kepler, but the systematic introduction of the convention was made by Gerard Desargues (1593–1662), chief among the founders of modern *pure* geometry. From that convention it readily follows, by the theory of similar triangles, that the (infinite) distances from any two finite points of a range to its infinite point are *equal*. The locus of the infinite points of the plane is a straight line, called *the infinite line* of the plane. As for space, the locus of its infinite points is a plane. In general the locus of the infinite points in a point-space of n dimensions is a point-space of $n-1$ dimensions. If a range rotate (in a plane) about one of its finite points, every other point of the range will generate a circle; the path of the infinite point being a straight line, the latter appears as a circle of infinite radius; a perfectly natural phenomenon, for the curvature, $1:r$, of a circle of radius r, vanishes for $r=\infty$.

Non-homogeneous and Homogeneous Coordinates of Point and Line of Range and Pencil.—In a range choose a point O for *origin* of distances. Denote by d the distance from O of an arbitrary point P of the range. Let $x=\rho d$, where the factor ρ may have any chosen value whatever. To any value of x there corresponds a position of P, and conversely. Hence x may serve as coordinate of the elements of the range. If a pencil be paired with a range as above, x will equally serve for coordinate of the lines of the pencil; or, in the latter case, d may be taken to represent the tangent of the angle made by a varying line of the pencil with a fixed line o, called *origin* of angles. Any point (line) of a range (pencil) will be represented by a linear equation $ax+b=0$, the coordinate of the element being $-b:a$. Conversely any element is defined by such an equation. In general n elements will give rise to an equation of nth degree in x, and any such equation will represent n elements. These (points or lines) will be real or *imaginary* elements of the range or pencil according to the corresponding character of the roots of the equation. All the equations can be rendered *homogeneous* by replacing x by the ratio $x_1:x_2$ and clearing of fractions. The quantities σx_1 and σx_2, σ being any chosen finite quantity called proportionality factor, are described as *homogeneous coordinates* of the point (line) of the range (pencil). The position of the element depends on the ratio of the quantities, which is the same as the ratio of the x's, and the element is accordingly spoken of as the point or line (x_1, x_2). One obvious advantage of the homogeneity thus introduced lies in the artistic quality, notably the symmetry, which it lends to the analysis; for example, the equation of a point assumes the form $a_1x_1+a_2x_2=0$; in particular, the equations of the origin and P_∞ are respectively $x_1=0$ and $x_2=0$. Obvious analogous interpretations hold for the pencil. Indeed it is at once evident that the geometry of the range and that of the pencil are *analytically one*. The algebra remaining the same, either geometry passes over into the other on a mere exchange of notions: point (line) for line (point), pencil (range) for range (pencil).

Geometric Interpretation of Homogeneous Coordinates.—In case of the range assume two origins O_1 and O_2 instead of one and let them be δ apart. These divide the range into two parts, the short segment *between* and the long one (including P_∞) *not* between O_1 and O_2. Strictly, any point of the range other than O_1 or O_2 is between these points, for the range is a *closed* figure, but the meaning of the preceding sentence is sufficiently clear. Let it be agreed that a point in the shorter segment is on the positive side of both O's, whence, naturally, a point in the longer segment will be on the positive side of the remoter, and on the negative side of the nearer, O. Denote by x_1 and x_2 respectively the distances of any point P from O_1 and O_2. For any P, $x_1+x_2=\delta$. To any pair of x's satisfying that relation there corresponds a point, and conversely. Hence the homogeneous coordinates σx_1, σx_2 of a point of a range are the distances (multiplied by any finite constant) of the point from two chosen fixed points. Analogously for the pencil, where, however, distances are replaced not by the angles but by the sines of the angles made by the variable line p with two fixed lines o_1 and o_2 and where it is understood that an angle and its vertical angle are one and the same angle.

Anharmonic Ratio.—The ruling notion in the doctrine of the range (pencil) is the *anharmonic* (double or cross) *ratio* of four elements. If x_1, x_2, x_3, x_4 be any four numbers (say any four values of a continuous variable x), the expression $(\overline{x_1-x_2}\cdot\overline{x_3-x_4}):(\overline{x_2-x_3}\cdot\overline{x_4-x_1})$ is called the anharmonic ratio of the four values taken in the order x_1, x_2, x_3, x_4, and is conveniently denoted by the symbol $(x_1x_2x_3x_4)$. If a one-to-one correspondence be established between the continuum of x-values and the elements of a geometric continuum, the notion of the anharmonic ratio of any four x-values may be and is associated with the corresponding four geometric elements, as the points of a range, the lines of a pencil, the planes of an *axal pencil* (assemblage of all planes containing a same line), and so on. The *order* of the elements is essential. The 24 possible permutations of 4 elements yield six (in general distinct) values of their anharmonic ratio. The exchange of two *alternate* elements, as x_2 and x_4, *inverts* the ratio. Thus, if $(x_1x_2x_3x_4)=r$, then $(x_1x_4x_3x_2)=1:r$. To exchange two *consecutive* elements, as x_2 and x_3, takes the *complement* of the ratio to 1. Thus $(x_1x_3x_2x_4)=1-r$. The six values are r, $1:r$, $1-r$, $1:(1-r)$, $(r-1):r$, $r:(r-1)$.

Geometric Interpretation of Anharmonic Ratio in Range and Pencil.—Let x_1, x_2, x_3, x_4 be the distances of the points P_1, P_2, P_3, P_4 of a range from the origin. Then x_1-x_2, x_3-x_4, x_2-x_3, x_4-x_1 represent, in sign and magnitude, the distances $\overline{P_1P_2}$, $\overline{P_3P_4}$, $\overline{P_2P_3}$, $\overline{P_4P_1}$. Hence

$(x_1x_2x_3x_4) = (P_1P_2P_3P_4) =$ the *ratio* of the *distance ratios* $\overline{P_1P_2}:\overline{P_2P_3}$ and $\overline{P_1P_4}:\overline{P_4P_3}$. In case of a pencil, if the x's denote the tangents of the angles α_1, α_2, α_3, α_4 made by the lines p_1, p_2, p_3, p_4 with the origin, or fixed line, o, then $x_1 - x_2$, . . . are the tangent differences $\tan\alpha_1 - \tan\alpha_2$, . . . , and $(x_1x_2x_3x_4) = (p_1p_2p_3p_4) = \{(\tan\alpha_1 - \tan\alpha_2)(\tan\alpha_3 - \tan\alpha_4)\} : \{(\tan\alpha_2 - \tan\alpha_3)(\tan\alpha_4 - \tan\alpha_1)\} = \{(\sin\overline{\alpha_1 - \alpha_2})(\sin\overline{\alpha_3 - \alpha_4})\} : \{(\sin\overline{\alpha_2 - \alpha_3})(\sin\overline{\alpha_4 - \alpha_5})\} =$ the *ratio* of the *sine ratios* $(\sin\overline{p_1p_2}):(\sin\overline{p_2p_3})$ and $(\sin\overline{p_1p_4}):(\sin\overline{p_4p_1})$, where p_ip_κ means the angle between p_i and p_κ reckoned from the former to the latter.

Special Relations of Four Elements.—These correspond to equalities among the six anharmonic ratios, and conversely. By equating r in succession to each of the other ratios, the following special values of the ratios are found: 1, -1, 0, ∞, 2, $\frac{1}{2}$, ω, and ω', the last two being the imaginary cube roots of -1. If $r = 1$, the six values are $1, 1, 0, 0, \infty, \infty$; if $r = -1$, the six are $-1, -1, 2, 2, \frac{1}{2}, \frac{1}{2}$; if $r = \omega$ or ω', they are $\omega, \omega, \omega, \omega', \omega', \omega'$; finally, if $r = 0$ or ∞, the six values are $0, \infty, 1, \infty, 1, 0$. The special relations accordingly fall into three cases, *viz.*, $r = 1$, $r = -1$, $r = \omega$. If $r = 1$, either $x_1 = x_3$ or $x_2 = x_4$, *i.e.*, two of the points (lines) coincide. Hence this case is called the *coincident* case. If $r = -1$, then, if s_1 and s_2 are the intervals into which the range (pencil) is divided by a pair of alternates, one element of the remaining pair is in s_1 and the other is in s_2; the pair x_1, x_3 is said to be *harmonically* related to the pair x_2 x_4; and conversely. In particular if one of the points bisects the finite segment s_1 the alternate point bisects the other segment s_2, *i.e.*, it is the infinite point of the range. And if one line bisects the angle s_1, the alternate line bisects the supplementary adjacent angle s_2. The case, $r = -1$, called the *harmonic* case, is of great importance, leading to the theory of *involution;* all point (line) pairs of a range (pencil) that are each harmonic (conjugate) to a fixed pair are said to constitute an involution of points (lines.) The case, $r = \omega$, is called *equianharmonic* (by Cremona) because the six values fall into two triplets, instead of three pairs, of equals. This case serves as a door for the entrance of imaginary elements into the geometry of the range (pencil), for obviously four *real* points (lines) cannot have an imaginary anharmonic ratio.

Conjoined Range and Pencil.—From any line a range is cut by any pencil, as in Fig. 1. If the elements be paired so that each line

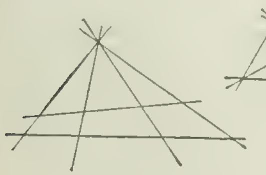

FIG. 2.

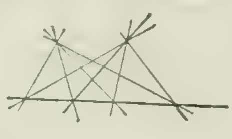

FIG. 3.

corresponds to the point it passes through, the range and pencil are said to be *in perspective* or to be *conjoined.* *Two ranges* (Fig. 2) conjoined with a same pencil are said to be *in perspective;* the vertex of the pencil is called the *centre* of perspective. Also *two pencils* (Fig. 3) conjoined with a same range are said to be *in perspective;* the base of the range is named *axis* of perspective. If a range and a pencil are conjoined and if P_1, P_2, P_3, P_4 be any four points of the range and p_1, p_2, p_3, p_4 are the corresponding lines of the pencil, then, by definition of anharmonic ratio, $(P_1P_2P_3P_4) = (p_1p_2p_3p_4)$, a theorem which in another form was known to Pappus (about 300 A.D.). It follows that corresponding anharmonic ratios of any two perspective ranges (pencils) are equal.

If the elements of two ranges or pencils or a range and a pencil be paired in such way that corresponding anharmonic ratios are equal, the two systems are said to be *projective.* Obviously, if the anharmonic ratio of four elements of which three are known be given, the fourth element is uniquely determined. It follows that any two projective systems can be placed in perspective. To place two projective ranges P_1, P_2, P_3, P_4, . . . , and P_1', P_2', P_3', P_4', . . . , in perspective, it suffices to place P_1 on P_1' and to take for perspective center the common point of the lines joining P_2 to P_2' and P_3 to P_3'. Similarly for two projective pencils.

The Anharmonic Ratio as Coordinate.—Let $(abcx) = r$ be the anharmonic ratio of four elements of which a, b, c are *fixed* and x is *variable.* To each value of x, *i.e.*, to each point (line) of the range (pencil), there corresponds one value of r, and conversely. Hence the anharmonic ratio r may be taken as coordinate of the point (line) of a range (pencil), referred to three arbitrarily taken fixed points (lines) of it. Now, $(\infty\ 1\ 0\ x) = x$; hence, if x in case of a range denote distance from the origin, it appears that the ordinary *distance-coordinate* of a point is its anharmonic ratio referred to the infinite point, the point 1 and the origin, of the range. Similarly, if for fixed lines be taken two perpendicular lines (of which one is the ordinary origin) and the bisector of their angle, the anharmonic ratio of those lines and a (variable) fourth line is the tangent (coordinate) of the angle of this line and the origin. The anharmonic ratio is thus seen to be the coordinate par excellence of the element of any one-fold continuum.

Linear Transformation.—The importance of the anharmonic ratio in the theory of simple continua comes clearly to view in connection with the linear transformation of them. The general equation of such transformation is $x' = (ax + b):(cx + d)$. To any point (line) x corresponds one point (line) x'. Viewing the transformation as an operation on all the elements at once, we say that each element x is transformed or converted into an element x'. Obviously the range (pencil) is converted into itself as a whole, the arrangement of the elements being in general changed. It is plain, too, that the transformation can be used to pair the elements of a range (pencil) with those of a pencil (range) or to pair two ranges or two pencils. The three independent ratios of the coefficients a, b, c, d are the parameters of the transformation. Hence there are ∞^3 transformations. Any two of them are equivalent to a third, and so they constitute a *group* (see GROUPS, THEORY OF); and the parameters

can be so determined as to convert any specified three elements into three specified elements. If x_1, x_2, x_3, x_4 be any four elements of a system (range or pencil) and if x_1', x_2', x_3', x_4' be the correspondents of the same or other system of the same or the other kind, then $(x_1x_2x_3x_4) = (x_1'x_2'x_3'x_4')$; *i.e.*, the anharmonic ratio is an absolute *invariant* (see INVARIANTS) under every transformation of the group. It is this property of invariance that lends the anharmonic ratio its great importance in geometry. Because anharmonic ratios are preserved by it, the linear transformation is called *projective:* any two systems paired by it are projectively related. Every transformation of a system into itself leaves two elements *fixed.* These are found by writing x for x' and then solving for x. The fixed elements, variously called the *poles, foci, double* or *conjugate* elements, of the transformation, will be real and distinct, coincident or imaginary, according as the *discriminant*, $D \equiv (d-a)^2+4bc$, is positive, zero, or negative; and the corresponding transformations are described respectively as *hyperbolic, parabolic,* and *elliptic,*—distinctions that cannot be here further pursued. In homogeneous coordinates the linear transformation is defined by the pair of equations $\rho x_1' = ax_1 + bx_2$, $\rho x_2' = cx_1 + dx_2$.

Range and Pencil; Dual Elements of the Plane.—Hitherto we have been mainly concerned with the line and the point (the range and the pencil) considered *in themselves.* These one-dimensional spaces are now to be viewed as *elements* of a twofold space, the plane. In Cartesian coordinates the equation of the line is $Ax+By+C=0$, or $ux+vy+1=0$. The equation, which represents the line as a *range* of points (x, y), contains *two* parameters u and v, which determine the range, or line. Hence the plane is two-dimensional in *ranges* (lines) as well as in *pencils* (points). Since one and but one line is determined by any pair of values of u and v, u and v may be employed as *coordinates* of the *line.* We may speak of the line (u, v) as of the point (x, y). If u and v vary and x and y do not, the equation *represents the point* (x, y) as a *pencil* of lines (u, v). We have here simple illustrations of three important *principles* of modern analytical geometry. As the equation of the line contains two independent parameters, we conclude that the plane is two-dimensional in lines. The dimensionality of any space in an element is always the number of independent parameters involved in the general analytic representation of the element. This principle of "enumerating constants" to determine questions of dimensionality is one of many principles introduced into analytical geometry by Julius Plücker (1801–1868). Another is that of *multiple interpretation* of equations. Thus we have seen that a same equation may be interpreted to represent now a point and now a line. Another great principle is that of *duality* or *reciprocity* introduced into *analytical* geometry by Plücker, though it was before employed in *pure* geometry by Poncelet (1788–1867) and his contemporary Gergonne, to the latter of whom geometric nomenclature is indebted for the word duality. Two elements e and e' of a given space are dual elements of it when its dimensionality is the same in both and when the analytic representations of e and e' are identical in form. Thus the point and the line (more properly, the pencil and the range) are reciprocal elements of the plane. The analogues for space are the point and the plane, the equation $ux+vy+wz+1=0$ representing either a plane (u, v, w) as a field of points or a point (x, y, z) as a *sheaf* (*bundle*) of planes. The mentioned reciprocity of the point and the line is immediately evident in such familiar pairs of propositions as: two points (lines) determine a line (point); three points (lines) determine three lines (points). In general, to any proposition about points (lines) corresponds an immediately derivable proposition about lines (points). So arise two parallel geometries of the plane, or, say, two reciprocal aspects of one geometry. The two algebras are one: dually interpretable. Using two variables, as ξ, η, to denote either point or line, any equation $f(\xi, \eta)=0$ will represent either a curve as an assemblage or *locus* of points or a curve as an assemblage or *envelope* of lines (tangents). The degree of the equation is called the *order* of the locus, *i.e.*, the number of points common to it and an arbitrary range, and it is called

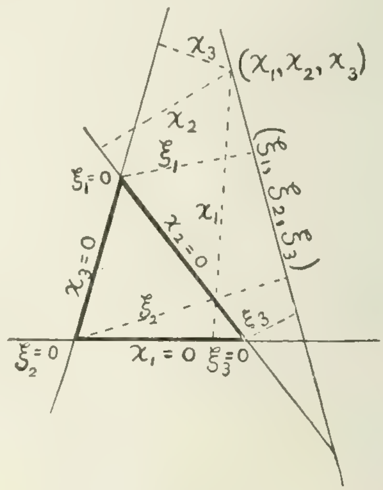

FIG. 4.

the *class* of the envelope, *i.e.*, the number of lines common to it and an arbitrary pencil. The two curves are in general not the same. But every curve, the point and line excepted, is conceivable as both a locus and an envelope and may at once be doubly generated as such: *i.e.*, by the figure of a point and a line through it so moving that the line is continuously tangent to the point's path at the point; such twofold genesis being another conception due to Plücker. Accordingly a curve has a point equation and a line (tangential) equation. For example, the ordinary point equation of the circle, centre at origin and radius r, is $x^2+y^2=r^2$; the line equation is $r^2(u^2+v^2)=1$. These are of the same degree, exemplifying the fact that every curve of *second* order is of *second* class, and conversely. In general, however, the order and the class of a curve are not equal; for example, the curve whose point equation is $x^3+y^3+1=0$ has for line equation the sextic, $u^6+v^6-2(u^3+u^3v^3+v^3)+1=0$, and is accordingly of order 3 and class 6.

Homogeneous Point and Line Coordinates and their Geometric Interpretation.—By replacing x by $x_1:x_3$, y by $x_2:x_3$, u by $\xi_1:\xi_3$, and v by $\xi_2:\xi_3$, all equations of loci and envelopes may be rendered homogeneous. In particular the equation of the line (point) becomes $\xi_1 x_1 + \xi_2 x_2 + \xi_3 x = 0$. The three ξ's (x's), or arbitrary multiples $\mu_i \xi_i$ ($m_i x_i$) of them, on whose two independent ratios the line (point) depends, are called the *homogeneous coordinates of the line* (*point*). Such coordinates admit of various closely allied interpretations of which the simplest is that, Fig. 4, in which the x's (ξ's) are the distances of the point (line) from the sides (vertices) of an assumed *fundamental* triangle, or triangle of *reference*, signs being so determined by convention that a point within the triangle is on the positive side of the three sides and that any two of the ξ's agree or do not agree in sign according as the corresponding line does not separate or separates the corresponding vertices. Such coordinates are often called *triangular* or *trilinear*. Plainly, they may be replaced by arbitrarily chosen multiples of them The x's (ξ's) are, of course, not independent. If Δ denote the area of the triangle and a_1, a_2, a_3 the lengths of its sides, the distances x satisfy the identity $a_1 x_1 + a_2 x_2 + a_3 x_3 = 2\Delta$. An analogous identity connects the ξ's. The x's and the ξ's need not be referred to the same triangle, but when they are (and that is generally the most convenient convention), the foregoing equation of the line (point) signifies also that the line and point it represents are united in position. Homogeneous coordinates were first employed, from mechanical motives, by Möbius in his 'Barycentrischen Calcul,' 1827, and by Plücker, from geometric motives, in his 'Analytisch-geometrischen Entwickelungen,' 1828. The artistic and economical device of denoting several coordinates by a single letter distinguished by subscripts was introduced by Hesse (1811–1874), whose 'Analytische Geometrie des Raumes,' 1861, remains a model of elegance.

The Method of Abridged Notation, and the Conics.—This powerful method, simultaneously and independently introduced into geometry by Plücker (cf. 'Entwickelungen,' above) and by Bobillier (*Annales de Gergonne*, vol. 18, 1827–8), consists primarily in denoting by a single letter the left-hand member of the equation of a curve or surface, whence the curve or surface is represented by placing the letter equal to zero. The advantages of the method, as combining ideally with the method of parameters and as greatly economizing at once both physical and intellectual energy, are obvious. For an illustration, let $P^i \equiv x_1{}^i\xi_1 + x_2{}^i\xi_2 + x_3{}^i\xi_3$ and $L^i \equiv \xi_1{}^i x_1 + \xi_2{}^i x_2 + \xi_3{}^i x_3$, then the equations $P^i = 0$, $L^i = 0$ will respectively represent a point and a line. If $P' = 0$ and $P'' = 0$ be two points, their range is represented by $P' + \lambda P'' = 0$, definite points of the range corresponding to definite values of the parameter λ; in like manner the pencil determined by two lines $L' = 0$ and $L'' = 0$ is $L' + \lambda L'' = 0$. In general the points (lines) common to any two loci (envelopes) $C' = 0$ and $C'' = 0$ are common to all the loci (envelopes) of the family $C' + \lambda C'' = 0$. If $\lambda' = (a\lambda + b).(c\lambda + d)$, the two pencils, $L' + \lambda L'' = 0$, $L''' + \lambda' L^{iv} = 0$, are projectively related. Any pair of corresponding lines determine a point. By elimination of λ and λ', the equation of the locus, Fig. 5, of all such points is found to be $aL'L^{iv} - bL''L^{iv} - cL'L''' + dL''L''' = 0$.

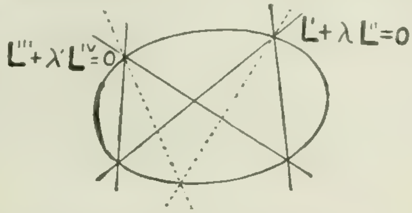

FIG. 5.

This being of second degree in point coordinates, the locus is of second order, a conic containing the vertices of the given pencils. Reciprocally, the envelope, Fig. 6,

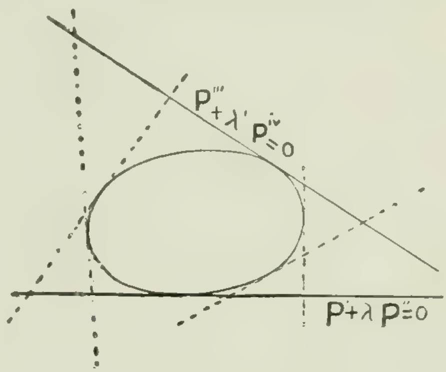

FIG. 6.

$aP'P^{iv} - bP''P^{iv} - cP'P''' + dP''P''' = 0$, of the lines joining corresponding points of two projective ranges, $P' + \lambda P'' = 0$, $P''' + \lambda' P^{iv} = 0$, is of second class, a conic touching the (bases of) the given ranges. The number and species of the conic depend on the ratios of the constants a, b, c, d. Obviously there are ∞^3 loci of second order (envelopes of second class) passing through two given points (touching two given lines).

Near-lying subjects such as the general conic, systems of conics, poles and polars, transformations, the circular points at infinity, circle and other geometries of the plane, cannot here be broached, much less the corresponding subjects in space.

Bibliography.—In addition to the works above cited, the following may be named as those which render the subject most readily accessible: Charlotte A. Scott, 'An Introductory Account of Certain Modern Ideas and Methods in Plane Analytical Geometry'; Fiedler's German edition of Salmon's 'Conic Sections' and 'Geometry of Three Dimensions'; Lindemann's 'Vorlesungen über Geometrie von Clebsch' (also in French, by Benoist).

CASSIUS J. KEYSER,
Adrain Professor of Mathematics,
Columbia University.

Geometry, Non-Euclidean. The primitive meaning of Non-Euclidean Geometry was the system which follows from the denial of Euclid's Postulate: «Through a given point there is not more than one parallel to a given straight

line,» when all of Euclid's other assumptions, explicit and unconscious, are retained.

It has sometimes been used in the sense of what Bolyai called Absolute Geometry and Lobachévski Pangeometry, namely, the system which simply dispensed with the above Euclidean Postulate, using neither it nor any contrary assumption; undifferentiated, therefore, as between Euclidean and primitive non-Euclidean.

When Euclid's tacit assumption, «the straight line is infinite,» is also dispensed with, we have Metageometry.

When this tacit assumption is denied, we have two new systems, to which the name non-Euclidean was immediately extended.

At present, by a non-Euclidean geometry is meant any system of geometry which, while differing in essential particulars from that of Euclid, is nevertheless in accord with experience and experiment, within the limits of the errors of observation. The space in which such a geometry is true is a non-Euclidean space.

The easiest way to get an appreciation of non-Euclidean geometry is to begin by following its early development historically.

The promise of its birth goes back almost to Euclid's very day, for it arose from endeavors to improve his treatment of the theory of parallels, which was the one point where his wonderful Elements had been criticised from antiquity. The attempts of Proklos and Claudius Ptolemæus to improve on Euclid here have been preserved to us. They were the first of a long line of geometers of every rank who have toiled over what they thought a blemish.

Such attempts may be classified under the three following heads:

1. *The Substitution of a Different Definition of Parallels.*—Euclid's own definition was: Two parallels are coplanar straights with no common point. It remains to this very day the only good definition of parallels for elementary geometry. The introduction of infinity in modern geometry gives its characteristic definition due to Desargues, 1639: Parallels are straights on a common point at infinity (figurative point). This has the advantage (1) of being freed from the necessity of specifying coplanarity, and (2) hence of giving an exact analogue for planes: Parallel planes are planes on a figurative straight; (3) of being wholly positive instead of chiefly negative; (4) of giving the dual in the plane of the fundamental «2 points determine a straight,» namely, «2 straights determine a point,» and hence the inestimable advantages of duality for the plane, including the doctrine of poles and polars.

But so far was the explicit use of infinity from being considered allowable in elementary geometry, that Borelli in 1658 objected to even so much of infinity as is implicit in Euclid's phrasing of «with no common point,» namely, «and which being produced ever so far both ways do not meet,» and so proposed as substitute: Parallels are straights with a common perpendicular

Géminos (about 100 B.C.) had defined parallels as straights everywhere equidistant, but Giordano da Bitonto (1680) saw that this presupposed the assumption of Clavius, 1574, that a line coplanar with a straight and everywhere equidistant from it is itself straight; so using a figure found in Clavius, made by joining together the ends of two equal perpendiculars to a straight, he tried to prove this join everywhere equidistant from the straight. This very figure reappears in Saccheri, of whom more anon.

Another definition is, Parallels are straights having the same direction. This also is worse than worthless.

2. *The Substitution of a Different Postulate.*—Of these the most famous is due to W. Ludlam, fellow of Saint John's College, Cambridge, who, in his 'The Rudiments of Mathematics' (1794), says: « The 12th axiom is not properly an axiom; but, instead of it, you may substitute the following simple proposition. Axiom: Two straight lines meeting in a point, are not *both* parallel to a third line.» This axiom has been persistently attributed to Playfair, despite the fact that he explicitly credits it to Ludlam in a note in his Euclid, on Prop. XXIX, where he says: «This axiom has been assumed by others, particularly by Ludlam, in his very useful little tract entitled 'Rudiments of Mathematics.' »

Other famous alternative postulates are those of Wallis, 1663: «To any triangle another triangle as large as you please can be drawn which is similar to the given triangle»; of Saccheri: «There is a triangle whose angle-sum is two right angles»; of Bolyai, F.: «Every three points are costraight or concyclic.»

3. *The Attempt to Deduce Euclid's Postulate from his Other Assumptions.*—The most famous is by Saccheri in his book 'Euclid Vindicated from Every Fleck' (Milan, 1733).

Ostensibly this is simply a very long demonstration of Euclid's Postulate by the indirect method, *reductio ad absurdum*. Denying this postulate and assuming a contradictory postulate together with all Euclid's other assumptions, if contradiction follows, this contradictory postulate is disproved. If thus the only possible alternatives to Euclid's Postulate are disposed of, it is demonstrated.

On the surface, then, it seems that Saccheri supposed himself to have proved the indemonstrable postulate.

If so, he has no claim to be the discoverer of non-Euclidean geometry. But upon a profounder study of his marvelous work, the suspicion comes that he knew the logical and mathematical truth of one at least of his non-Euclidean hypotheses and the consequent final and eternal indemonstrability of Euclid's Postulate. In that case, he cherished his work, just as we do, not for its fallacious conclusion, necessitated to get for his book the *imprimatur* of the Inquisition and of the Society of Jesus, Saccheri being a Jesuit, but for the beautiful non-Euclidean results which immortalize it.

The angles at the extremities of two equal perpendiculars are equal and either right, obtuse, or acute. These are Saccheri's three hypotheses: the hypothesis of right angle, the hypothesis of obtuse angle, the hypothesis of acute angle.

The first is Euclid. The last is the primitive non-Euclidean geometry.

This was consciously discovered by Schweikart in 1812 at Charkow, communicated to Bessel, and in 1818 a written statement of it sent to Gerling which he was afterwards asked to transmit to Gauss. He did so, and thus

this precious document, the first published (not printed) non-Euclidean geometry, is still preserved. (Translated by Halsted, 'Science,' N. S., Vol. XII, pp. 842–846.) Two of its theorems are: (*a*) The sum of the three angles in the triangle is *less* than two right angles; (*b*) This sum becomes smaller the more content the triangle encloses.

The first to print a non-Euclidean geometry (1829–30) was a Russian-Lobachévski, professor of mathematics in the new University of Kazan.

In place of Euclid's Postulate he substitutes the following, which directly contradicts it: «All straight lines which, in a plane, radiate from a point, can, with reference to any given straight line in the same plane, be divided into two clasess—into *cutting* and *not cutting*. The *boundary lines* of the one and the other class are called *parallel to the given line.*»

If the length of the perpendicular from the given point to the given straight line be p, the acute angle it makes with either of the two parallels is denoted by $\Pi(p)$. With a suitable choice of the unit of length, $\tan \frac{1}{2}\Pi(p) = e^{-p}$.

Lobachévski never claimed to have discovered the non-Euclidean geometry before 1826, and the tell-tale title of his paper of 1826, 'Exposition succincte des principes de la Géométrie avec une demonstration rigoreuse du théorème des parallèls,' has never been explained.

Even in 1837 in Crelle's Journal he made the mistake of calling his discovery «Géométrie Imaginaire.»

How different the brilliant young Hungarian, John Bolyai, who in 1823 had written to his father Bolyai Farkas (Wolfgang Bolyai): «I have discovered such magnificent things that I am myself astonished at them. It would be damage eternal if they were lost. *From nothing I have created another wholly new world.*»

His brief exposition of this new world, with the same unflinching recognition of its momentous importance, he calls «The Science Absolute of Space.» It is the most extraordinary two dozen pages in the history of human thought. It was published in 1831 as an appendix to the first volume of a work by his father.

In this tiny appendix, with unparalleled boldness and power, the young Magyar hero squares the circle in Bolyai space, shows that the area of the greatest possible triangle (which has all its sides parallel and all its angles zero) is πi^2, where i is what is now called the space constant, shows how through a given point to draw a parallel to a given straight, and how to draw a perpendicular to one arm of any acute angle which shall be parallel to its other arm.

To get a sharp idea of this primitive non-Euclidean geometry, which may be named after either Lobachévski or Bolyai, contrast a few of its theorems with some of Euclid's:

Proposition 32, Book I of Euclid, is that the sum of the angles in every rectilineal triangle is *just exactly* two right angles. In Bolyai geometry, on the contrary, the sum of the angles in every rectilineal triangle is *less* than two right angles.

In the Euclidean geometry parallels *never* approach. In this non-Euclidean geometry parallels *continually* approach.

In the Euclidean geometry all points equidistant from a straight line are on a *straight* line. In this non-Euclidean geometry all points equidistant from a straight line are on a *curve* called the equidistantial.

In the Euclidean geometry the limit approached by a circumference as the radius increases is a *straight* line. In this non-Euclidean geometry this limit is a *curve* called the oricycle. Thus the method of Kempe's book, 'How to Draw a Straight Line,' would here draw not a straight line, but a curve.

In the Euclidean geometry, if three angles of a quadrilateral are right, then the fourth is *right*, and we have a rectangle. In this non-Euclidean geometry, if three angles of a quadrilateral are right, then the fourth is *acute*, and we never can have any rectangle.

In the Euclidean geometry two perpendiculars to a straight line remain *equidistant*. In this non-Euclidean geometry two perpendiculars to a straight line *spread away from each other* as they go out; their points two inches from the straight line are farther apart than their points one inch from the line.

In the Euclidean geometry every three points are either on one straight line or on one circle. In this non-Euclidean geometry there are triplets of points which are *neither costraight nor* concyclic. Thus three points each one inch above a straight line are neither on a straight line nor on a circle.

In 1867, after Riemann's death, was published an inaugural lecture he had delivered in 1854: 'On the Hypotheses which are at the Foundation of Geometry.' Here occurs for the first time the extraordinary advance that the straight line may be closed and finite; that space though unbounded may still be finite, that, for example, a finite number of our common building bricks might be written down which might be more than our universe could contain. This at once gave Saccheri's «hypothesis of obtuse angle» equal standing with his other two, giving a new genus of non-Euclidean geometry, the Riemannian, with two species, the elliptic and the spheric. These varieties of Riemann's space are also called the polar and antipodal forms of elliptic space, Euclid's space being called parabolic, and that of Bolyai and Lobachévski hyperbolic, space. Riemann gets his profound hold of this matter with the aid of two fundamental conceptions, that of a *manifold*, and that of what he called the *measure of curvature* of a continuous manifold having flatness in its smallest parts. This phraseology, especially the use of the word curvature, proved unfortunate, misleading philosophers and even mathematicians into supposing non-Euclidean spaces curved and necessarily contained in Euclidean spaces. How far this is from being the case is shown by the beautiful «Theorem of Barbarin»: «Each of the three spaces, Euclidean, Lobachévskian, Riemannian, contains surfaces of constant curvature of which the geodesic lines have the metric properties of the straight lines of the three spaces.» Riemann himself created point-manifolds with measure of curvature not zero utterly without reference to anything not contained in the manifold itself. Hence to avoid all appearance of implying for non-Euclidean spaces a curva-

ture in Euclidean space, the phrase *space-constant* serves, it being equal to the reciprocal of the square root of Riemann's measure of curvature.

Lambert in his 'Theorie der Parallellinien' (1766), showed that Saccheri's «hypothesis of obtuse angle» holds on a sphere, and to-day pure two-dimensional spherics is not only the best Euclidean analogue of a Riemannian geometry, but inversely the geometry of two-dimensional antipodal Riemannian space gives the best insight into Euclidean spherics and spherical trigonometry. These reciprocal advantages will be found utilized in Chapter XV, *Pure Spherics*, of Halsted's 'Rational Geometry,' which may be taken as the simplest, most detailed, most complete Riemannian geometry in print.

But it must not be supposed that the surface of a sphere *is* a plane of antipodal Riemannian space. They have the same internal relations, abstraction made of all points not *on*, that is, *in* them. To realize how tremendously different they are in other respects, you have only to recall that the sphere has a triple infinity of points within it, including the center, while the antipodal Riemannian plane has no points within it, no points toward which it is concave.

In the polar form of Riemannian space two coplanar straight lines always intersect once and only once. A complete straight line does not divide a plane; a plane does not divide space, it is unilateral. In this space alone do we have complete, absolute point and plane duality.

Another genus of Euclidean analogues of non-Euclidean spaces was obtained by Klein by a variation of the absolute in Cayley's projective metrics. The coordinates employed in the projective foundation of metrics must be defined non-metrically. This is accomplished by means of the pure projective geometry of von Staudt founded on his famous quadrilateral construction, by which, entirely without any metrical presuppositions, order is assigned among the points of a line. This Cayley-Klein translation of non-Euclidean systems furnished a final proof that no logical outcome of a non-Euclidean geometry could ever be self-contradictory, since any self-contradiction in a non-Euclidean system would be but a like self-contradiction in the Euclidean system. Another equally sweeping but much simpler proof of this on the same principle is given by Poincaré in his remarkable book, 'Science and Hypothesis.'

To the genius of Helmholtz is due the conception of studying the essential characteristics of a space by a consideration of the movements possible therein. Felix Klein it was who first called the attention of Lie to this work of Helmholtz, and pointed out its connection with Lie's group-theory. In 1886 Lie gave briefly his weightiest results. The whole investigation, published in Vol. III of his 'Theorie der Transformationsgruppen,' 1893, was in 1897 awarded the first Lobachévski Prize, a great recurring prize founded at Kazan by contributions from all over the world in honor of the Russian creator of the first non-Euclidean geometry. If Hungary had a man like Vasiliev of Kazan, she too would be honoring herself by marking with a Bolyai Prize her pride in the greatest idea which ever originated in a Magyar brain.

Lie proves that free motion in the strict meaning of the word can happen in three and only three spaces, namely, the traditional or Euclidean space and the two kinds of non-Euclidean space, a Bolyai space, a Riemann space, of which latter there are two species. These four are thus the only spaces allowing free motion as a whole.

A new genus of non-Euclidean spaces, forms of space which do not allow free motion as a whole, called by Killing the Clifford-Klein spaces, may be said to have arisen from Clifford's unbounded surface of finite extent and zero curvature, whose connectivity and geometry are those of a plane Euclidean parallelogram whose opposite sides correspond point for point, these opposite pairs being considered as one point. The connectivity is that of an anchor-ring.

In this the moving on itself of the closed surface in its totality is sharply restricted, while the movements of a comparatively small area on the closed surface remain unrestricted. Clifford's surface is the locus in the polar form of Riemannian space of the point whose perpendicular to a given straight is congruent to a given sect, that is, of points at a constant distance from a given axis. This locus is a ruled quadric surface. The joins of the correlated points of two projective ranges whose bearers are not coplanar form a «ruled system» or regulus of straights no two coplanar. For were two coplanar, then two points on the bearer m and two on the bearer m_1 would all four be on this plane, and so m and m_1 coplanar, contrary to hypothesis.

Let the straights n, n_1, n_2 be any three of the elements of a ruled system, and N_2 any point on n_2. Put a plane on N_2 and the straight n_1, and let its pass with n be called N. The straight NN_2 cuts n, n_1, n_2 all three. Projecting the generating ranges of the ruled system (on the bearers m and m_1) from the straight NN_2 (or m_2) as axis produces two projective axial pencils, which having three planes m_2n, m_2n_1, m_2n_2 self-corresponding are identical. Therefore every pair of correlated points of the ranges on m and m_1 is coplanar with m_2; that is, m_2 cuts every element of the ruled system.

By varying the point N_2 we obtain ∞^1 straights, all cutting all the ∞^1 straights of the original ruled system and making on every two projective ranges. Of the straights so obtained no two cross, for that would make two of the first ruled system coplanar. Either of these two systems may be considered as generating a «ruled surface,» which is the bearer of both.

Each of the two systems is completely determined by any three straights of the other, and therefore so is the ruled surface also. From the construction follows that the straights of either ruled system cut all the straights of the other in projective ranges. So any two straights of either system may be considered as bearers of projective ranges generating the other system, or indeed the ruled surface. On each point of this ruled surface are two and only two straights lying wholly in the surface (one in each ruled system). The figure of two so united ruled systems, due to Monge, is one of the most noteworthy creations of modern geometry.

In Clifford's surface any two of the elements of the same ruled system have an infinity of common perpendiculars all congruent, as have also any element and the axis of the surface Clifford called all the elements of the same ruled system '*parallel*' to each other and to the axis.

Generalizing, a transformation in this polar space of three dimensions in which all straights of a certain straight-congruence remain fixed while any point is displaced along the straight of the congruence on which it lies is called a *translation*, and the straights of the congruence are called *Clifford Parallels*. From any point of either of two Clifford parallels a common perpendicular can be drawn to the two, and all such are congruent. Moreover, if a straight cut two Clifford parallels, the corresponding angles are congruent.

The Clifford parallels are of two kinds, according as the generators of the fundamental quadric which determine them are elements of one or the other of the two ruled systems of the quadric. Similarly translations are to be distinguished as of two kinds. Two successive translations of the same kind are equivalent to a translation, but two translations of different kinds are not equivalent to a translation.

From these considerations we get, even when the measure of curvature is taken as zero, by the side of ordinary Euclidean space three other types or species of the genus Clifford-Klein space, given by the use of translations alone. These may be studied from the Euclidean geometry: 1° Within a parallelopiped with three finite edges; 2° Within a parallelopiped one of whose edges becomes infinite; 3° Within a parallelopiped two of whose edges become infinite.

In the Clifford-Klein space corresponding to 1°, geodesics may have the finite length $la+mb+nc$, where a, b, c are the lengths of the edges of the parallelopiped and l, m, n are any three relatively prime integers. Geodesic surfaces may be like a plane, a cylindric, or an anchor-ring surface.

If, finally, the same considerations be applied to the case where the measure of curvature is a negative constant, there results an infinity of varieties corresponding exactly to the configurations considered by Poincaré and Klein in the theory of automorphic functions. The great importance of the Clifford-Klein space-forms rests upon this, that they show with especial clearness what a mighty difference it makes whether we, from the beginning, assume the geometric axioms as valid for space as a whole or merely for an every way bounded piece of space. In the first case we obtain, besides the Euclidean, only the three now well-known non-Euclidean space-forms. In the second case appears also a manifold, at present not yet dominated, of different space-forms, new non-Euclidean universes.

Bibliography.—A bibliography of non-Euclidean literature down to the year 1878 was given by Halsted, 'American Journal of Mathematics,' Vols. I, II, containing 81 authors and 174 titles, and reprinted in the collected works of Lobachévski (Kazan, 1886) giving 124 authors and 272 titles, which was incorporated in Bonola's 'Bibliography of the Foundations of Geometry' (1899), reprinted (1902) at Kolozsvár in the Bolyai Memorial Volume. Bonola adds the titles of 27 articles written by Halsted, a study and synthesis of which will be found in 'Euclid's Parallel Postulate' (Chicago, 1905, pp. i–x, 1–192). See also 'Report on Non-Euclidean Geometry' (American Association, 1899, and Supplementary Report on Non-Euclidean Geometry, 1901).

Saccheri, rediscovered, was first given to the world by a translation in the 'American Mathematical Monthly' (Vols. I and II). Lobachévski and Bolyai we have in the 'Neomonic Series,' published at The Neomon, Gambier, Ohio: (Vol. I); Vasiliev's 'Address on Lobachévski': (Vol. III); Bolyai's 'Science Absolute of Space': (Vol. IV); Lobachévski's 'Geometrical Researches on the Theory of Parallels': (Vol. V); 'Introduction to Lobachévski's New Elements of Geometry.' In French, 'La Géométrie non euclidienne;' par P. Barbarin, is a little gem. In German, for exposition, 'Nichteuklidische Geometrie,' von H. Liebmann (1905); for the sources, Stäckel and Engel, 'Die Theorie der Parallellinien' (1895); Engel, 'Lobatschefskij' (1899).

GEORGE BRUCE HALSTED,
Professor of Mathematics, Kenyon College, Gambier, Ohio.

Geometry, Pure Projective. *Introductory.*—Projective geometry, as the name indicates, has to do with the theory of projection. Pure projective geometry is that which is conducted by means purely geometric, without initial recourse to algebraic methods (see GEOMETRY, MODERN ANALYTICAL), and which makes only subordinate mention of properties other than projective. The adjective synthetic is frequently used as practically a synonym for pure.

The process of projection is of constant occurrence—*e.g.*, in photographing (the lens must be strictly rectilinear), in preparing a lantern-slide from the photographic plate, and in throwing the image upon a screen. Thus in passing from an object to its representation upon the screen there are three successive projections—a fourth enters with the visual image formed upon the retina when the screen is viewed. Fig. 1 serves to illustrate the process of projecting a line $ABCD$ into another $A''B''C''D''$.

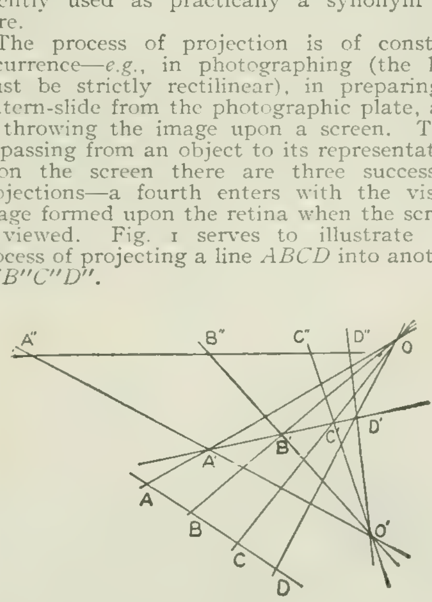

FIG. 1.

Reference to the figure will show that the length of a line is changed by projection AB is not equal to $A''B''$. Moreover, even the ratio of two lengths is changed. $AB \div BC$ is

not equal to $A''B'' \div B''C''$. The study of projective geometry is the study of such properties of figures as are unaltered by successive projections. Lengths and ratios of lengths are not such properties, and by right enter only subordinately into pure projective geometry.

Historically considered, projective geometry arose by considering changes in lengths, and was thus far from pure. A theorem attributed to PAPPUS (q.v.) states that the *double ratio* of the lengths is unchanged by projection—thus,

$$\frac{AB}{BC} \div \frac{AD}{DC} = \frac{A'B'}{B'C'} \div \frac{A'D'}{D'C'} = \frac{A''B''}{B''C''} \div \frac{A''D''}{D''C''}.$$

It was upon such basis as this that the subject developed until VON STAUDT (q.v.) in his famous 'Geometrie der Lage,' published in 1847, showed how the development might proceed in a manner more truly in the spirit of pure projective geometry. From the publication of this book dates the modern point of view in treating projective geometry as a pure self-sustaining branch of mathematics. It is this point of view that is here adopted.

Fundamental Notions.—Properly to appreciate pure projective geometry it is necessary definitely to take a point of view radically distinct from that taken in ordinary elementary geometry. This may perhaps be done best by making a first appeal, as von Staudt did, to the physical sensation of sight. What characterizes ordinary geometry (which is usually called *metrical*, as opposed to projective geometry) is its close relation to the conceptions of rigid motion, of distance, and of measurement—in short, to things connected with the sensation of touch. Whereas projective geometry is intimately concerned with the look (Schein) or projection of objects and not with their actual dimensions. Thus in the figure the set of points A, B, C, D would have the same 'look' to an observer at O as would A', B', C', D'; and these in turn would appear the same from the point O' as would A'', B'', C'', D''. There is, however, one respect in which the idea of 'looking' must be generalized. If the view-point is situated between the points A', B', C' and A'', B'', C'', as in Fig. 2,

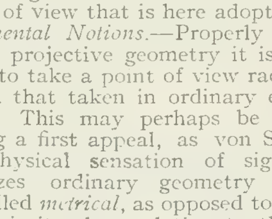

FIG. 2.

the sets of points are still said to 'look' the same, or to be projections of one another with respect to the point O'. Precisely herein lies the distinction between projective geometry and what has been called descriptive geometry (B. Russell, 'Principles of Mathematics,' p. 393). Namely, the former considers the line of vision or projection to be the whole line through the point of observation, whereas the latter takes it as merely a half-line and thus corresponds somewhat more closely to the real visual space.

The point, the straight line, and the plane are assumed as the fundamental geometric elements. They are denoted respectively by italic capitals A, B, C, . . . ; by lower case italics, a, b, c, . . . ; and by Greek letters, α, β, γ, . . . It may be noted that these elements are themselves projective, that is, appear respectively as points, line, and plane from any view-point not situated upon them. A circle has not this property: for when viewed from any point, not upon the line through its center and perpendicular to its plane, it appears noncircular. Hence the circle could not serve as a fundamental locus in pure projective geometry.

Fundamental Propositions. Parallelism.—There are a considerable number of immediately obvious relations connecting the fundamental elements, points, lines, planes. From among these it is necessary to select a certain number to serve as fundamental propositions or premises for future deductions. (Note. The propositions so selected may be called axioms or postulates. This, however, is not the place to discuss such matters, which belong to the foundations of mathematics. See LOGIC, SYMBOLIC.)

F. P. 1. Two points determine a line—the line joining them and upon which they lie.

F. P. 2. Two planes determine a line—their line of intersection and through which they pass.

F. P. 3. Three points not in the same line determine a plane—the plane passed through them and in which they lie.

F. P. 4. Three planes not passing through the same line determine a point—their point of intersection.

F. P. 5. A point and a line not passing through the point determine a plane.

F. P. 6. A plane and a line not lying in the plane determine a point—their point of intersection.

From these propositions follow a number of theorems:

Th. 1. If two points lie in a plane, the line joining them lies wholly in the plane. Proved from F. P. 3 and F. P. 5.

Th. 2. If two planes pass through a point, their line of intersection passes through the point. Proved from F. P. 4 and F. P. 6.

Th 3. If two lines have a point in common, they determine a plane. Proved by F. P. 3 and Th. 1.

Th. 4. If two lines lie in the same plane, they intersect in a point. Proved by F. P. 4 and Th. 2.

Th. 5. If two triangles are so situated that the lines joining corresponding vertices meet in a point, the points of intersection of corresponding sides lie on a line.

The proof in case the triangles do not lie in the same plane is as follows: Let ABC and $A'B'C'$ be the triangles. As AA' and BB' meet in a point, the lines AB and $A'B'$ determine a plane (Th. 3, Th. 1) in which they intersect (Th. 4). But as AB lies in the plane ABC, and $A'B'$ in the plane $A'B'C'$, they can only intersect on the line common to these two planes. Hence the intersection of AB and $A'B'$ is on this line. Similarly BC and $B'C'$, and CA and $C'A'$, intersect on this line. The proof in case the triangles lie in the same plane is obtained by comparing each of them with a triangle out of their plane.

Th. 6. Converse of Th. 5. Proof similar.

Th. 7. If two triedral angles are so situated that the lines of intersection of corresponding faces lie in a plane, the planes determined by corresponding edges pass through a line. The proof follows that of Th. 5.

Th. 8. Converse of Th. 7. Proof similar.

From the point of view of elementary geometry theorem 4 is incorrect and should read 'if two lines lie in the same plane they either intersect or are parallel.' What has become of parallelism? Reflexion will disclose that for projective geometry there is no such thing as parallelism. For, consider two parallel lines upon a horizontal plane and project them upon a vertical plane (as is done in photographing a straight, flat railroad track). In the projection the lines meet upon the horizon (Fig. 3). Thus the property

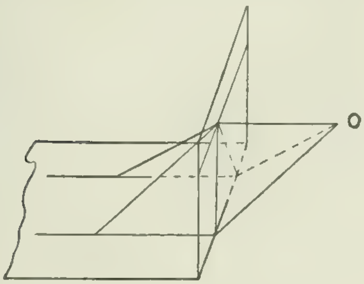

Fig. 3.

known as parallelism in elementary geometry is not unchanged by projection and cannot enter into projective geometry. From the visual point of view all lines seem to intersect. F. P. 2, F. P. 4, and F. P. 6 are subject to the same comment. From this it will be seen that the statements for projective geometry are much simpler than those for elementary geometry, inasmuch as no special cases or exceptions need be introduced to cover the possibility of parallelism. At first this might seem unnatural or even wrong, but it is in the true spirit of the subject and after a little usage appears as one of the principal beauties.

The expression is often used that parallel lines and planes meet "at infinity." This is convenient in expressing the relations of projective to elementary geometry (§ 7), but it must not be allowed to introduce confusion. There is no such thing as distance, much less infinite distance or infinity, in pure projective geometry. (See, however, § 8.)

4. *Harmonic Elements. Duality.*—A set of points situated upon a line is called a *range.* A set of planes passing through a line is called a *pencil* of planes. A set of lines lying in a plane and passing through a point is called a *pencil* of lines.

It may be said that the fundamental construction of projective geometry is the construction of a harmonic range. Given a pair of points A, B on a line (Fig. 4) and a third point C. To find the fourth harmonic point D draw through C any line. In the same plane draw AE and BE cutting the line through C in F and G. Join F to B and G to A by lines intersecting in H. Draw the line connecting E and H, and let it cut the line AB in D. Then D is said to be the fourth harmonic point in the range $AB \cdot C$. It may be proved by the theorems given above that: 1° no matter how the construction be carried

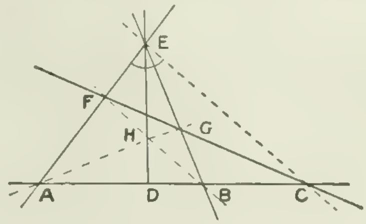

Fig. 4.

out, it always leads to the same point D; 2° if the three given points be $AB \cdot D$, the fourth harmonic is C, and hence the pair of points C, D may be said to divide the pair A, B harmonically; 3° the pair A, B also divide C, D harmonically, and hence the pairs $AB \cdot CD$ may simply be called harmonic pairs or a harmonic range.

A pencil of lines such as $E\text{-}AB \cdot CD$ which cuts a line in a harmonic range is by definition a harmonic pencil. It may be shown that if any line cuts a harmonic pencil, the range of points is harmonic. Similarly if a pencil of planes cuts one line in a harmonic range, it cuts every line in a harmonic range and is said to be a harmonic pencil. The harmonic property is thus evidently a true projective property, being unchanged by projection.

A characteristic of higher geometry is the frequent use of correspondences—that is, of methods for obtaining from a given group of theorems another group merely by substituting different words in the statement of the given theorem. The simplest of these correspondences is *duality.* There are several dualities established in projective geometry. Of these the most important are duality in space and duality in the plane.

Spatial duality is obtained by substituting respectively for 'point,' 'line,' 'plane,' the words 'plane,' 'line,' 'point,' and making such corresponding changes from 'pass through' to 'lie on' as may be necessary. In the fundamental propositions the duality appears. Thus F. P. 1 and F. P. 2 are dual statements. The same is true of F. P. 3 and F. P. 4 and of F. P 5 and F. P. 6. As this dual relation extends through all the fundamental propositions, it must extend through all propositions immediately derived from them. For, the proof of a dual proposition may be given by merely making in the proof of the given proposition the same changes as in its statement. As this may be done at every step, the two sets of propositions may be developed side by side, and the duality can never break down until the introduction of some additional definition or fundamental proposition which is not accompanied by its dual. Thus Th. 1 and Th. 2 are dual, and the proof of Th. 2 is the exact dual counterpart of the proof of Th. 1.

The duality in the plane may be obtained by substituting for 'point' and 'line' the words 'line' and 'point.' A 'range of points' becomes a 'pencil of lines' and *vice*

versa. Thus Th. 1 and Th. 4, and in case the construction be confined to a plane Th. 5 and Th. 6, are duals. According to the definitions above given it did not appear that the harmonic pencil was the dual of the harmonic range. It is, however, possible to give for a harmonic pencil a construction which is the dual of that given for the range, and it may be proved that this construction is equivalent to the earlier definition. Therefore all theorems concerning harmonic properties have dual counterparts.

If four lines no three of which pass through the same point be drawn in the plane, they will intersect in six points. This figure is called the *complete quadrilateral* (the heavy lines of Fig. 4, except *ED*. The three dotted lines are the three diagonals). In a dual manner the six lines which may be drawn through four points (no three of which lie on a line) in the plane constitute the *complete quadrangle.* The properties of these two figures are much studied in plane projective geometry.

5. *Order, Continuity, Projectivity, Correlation.*—If three lines a, b, c, lying in a plane, pass through a point, they determine a certain *order* in which the pencil may be conceived as described by a movable line—the order *abc* to which *cba* is opposed. Two lines alone cannot determine the order of description: for it is possible to pass from one to the other in either of two ways. Similarly three points upon a line determine an order upon the line, and three planes through a line fix an order about that line: but two cannot (see § 7). Thus a new element, *order*, is added to the fundamental elements, point, line, plane. It is intuitively obvious that:

F. P. 7. Order is unchanged by projection. Thus if a point describe a range in the order ABC, its projection will describe the projected range $A'B'C'$ in the same order (see Figs. 1 and 2).

One more fundamental proposition, the so-called postulate of continuity, the importance of which is quite overlooked in all but the best and most recent works, may be stated as follows:

F. P. 8. If a line be ordered and if Y follow X in that order; if, moreover, the points of the segment XY be divided into two classes so that 1° every point of the segments belongs in one of the classes and 2° every point of one class precedes all points of the other class, then there must be a point Z in the XY such that every point which precedes Z lies in the first class and every point which follows Z lies in the second.

If one range may be obtained from another by successive projection, the two ranges are said to be projective. The relation between the ranges is called a *projectivity.* (Similar definitions cover the relations between ranges and pencils or between two pencils. For simplicity the treatment will be confined to ranges.)

Fundamental Theorem.—Three corresponding points A, B, C and A', B', C' determine uniquely the projectivity between two ranges. That three elements of one range may be projected into any three elements of another range may be seen from Fig. 2. That the projective relation is thereby uniquely determined follows from F. P. 8. In like manner the correspondence of four points, no three of which lie on a line, determines the projectivity between two planes (which may coincide); and five points determine the projectivity between two spaces (these must coincide).

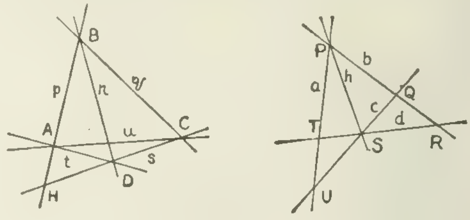

Plate I. Plate II.

Fig. 5

If the points of one plane are placed in correspondence with the lines of a second plane (which may be coincident with the first) in such a manner that to each point corresponds one line and conversely, and to the intersection of two lines corresponds the line joining their corresponding points, the relation is called a *correlation.* A correlation is completely determined by the correspondence of four given elements. (In the figure corresponding elements have the same letters.)

6. *Conics.*—If in one and the same plane a correlation be so established that when the point P corresponds to the line p, then conversely the line p corresponds to the point P, the correlation is called a *polarity.* Corresponding points and lines are *poles* and *polars* in the polarity. In general the poles do not lie on the polars: but certain of the poles do usually lie on their polars. The locus of the poles which lie on their polars is a curve to which the polars themselves are tangent and is called a *conic.* This definition is self-dual. A large number of theorems and their duals follow from the definition. For example, with their duals:

1. Pole, polar, and conic cut out a harmonic range on any line through the pole.

2. The locus of the intersections of corresponding lines of two projective pencils is a conic.

3. If a hexagon be inscribed in a conic, the points in which the three pairs of opposite sides intersect lie on a line.

This last is the famous Pascal's theorem, which with its dual, Brianchon's theorem, is very useful in the theory of conics. The second theorem is taken to define conic sections by many less modern writers. It is a very convenient graphical method. From it the various other properties may be deduced, though with much less directness and power than in the way here sketched. The first theorem is taken to define pole and polar by most of the writers who base conic sections on the second theorem. Another method of treating poles and polars is to consider projectivities not merely on a line but on a conic. The points of a conic are associated so that to each point A, B, C, . . . , corresponds a point A', B', C', . . . Three pairs of corresponding points determine the projectivity. If it so happens that A', B', C', . . . , correspond conversely to A, B, C, the projectivity is called *involutory* (just as the polarity

was the involutory correlation, § 4) or merely an *involution*. The study of involutions on a conic leads to an elegant theory of poles and polars.

Quadric surfaces may be defined analogously to conic sections. The treatment of cubic curves on such surfaces has been considerably developed. The treatment of plane curves of order and class higher than conics may be developed to some extent synthetically, but is generally carried on analytically (see CURVES, HIGHER PLANE). The linear and tetrahedral line complexes and certain line congruences have received synthetic treatment. The analytical discussions are, however, better known (see GEOMETRY, LINE-).

7. *Relations to Metrical Geometry.*—If the word meet be changed to meet or are parallel, every theorem of projective geometry becomes a theorem of metrical geometry. But in order conversely to interpret a metrical theorem as a theorem of projective geometry, it is first necessary to state the theorem in terms unchanged by projection—that is, in terms of double ratios (§ 1). This is usually done in one of two ways.

First, if the point D retreats indefinitely, AD/DC approaches -1 and the double ratio

$$\frac{AB}{BC} \div \frac{AD}{DC}$$

approaches the simple ratio AB/CB. Thus any ratio in metric geometry may be turned into a double ratio and rendered projective by adding the point at infinity upon the line to the three finite points A, B, C. In the particular case of a harmonic range (§ 4) $AB \cdot CD$ if D be at infinity, C bisects AB. This introduction of a point at infinity also accounts for the fact that a pair of points AB suffice in metric geometry to determine an order on the line (§ 5). The order is that of $AB\infty$.

The relation between metric and projective geometry may be used to obtain metrical theorems from projective theorems by specialization of the figure, or to obtain projective theorems from metrical by generalizing the figure by projection. Thus the theorems «the diagonals of a parallelogram bisect each other» and «a diagonal of a complete quadrangle is divided harmonically by the other two diagonals» may be obtained one from another. (See Fig. 4.)

Second, the double ratio of four lines a, b, c, d may be written as

$$\lambda = \frac{\sin \measuredangle ab}{\sin \measuredangle bc} \div \frac{\sin \measuredangle ad}{\sin \measuredangle dc}.$$

If only a simple angle such as $\measuredangle bd$ is given, the two other lines of the pencil may be assumed to be the «minimal lines» or «lines to the two circular points» determined by

$$x \pm \sqrt{-1}\, y = 0.$$

The double ratio λ becomes

$$\lambda = e^{2\phi i} = \cos 2\phi + i \sin 2\phi,$$

$$\phi = \frac{1}{2i} \log \lambda.$$

Thus an angle ϕ has been expressed in terms of a double ratio λ by the introduction of the two circular points. If, in particular, ϕ is a right angle, $\lambda = -1$, and the pencil is harmonic.

The properties of circular points most necessary to establish the relation of metrical to projective geometry are: They lie on the line at infinity. All circles pass through them. The lines (imaginary) joining the center of a circle to the circular points are tangent to the circle. Thus the theorem «the locus of the vertex of a right angle (or any angle) whose sides pass through two fixed points is a circle through the fixed points» becomes «the locus of the vertex of a harmonic pencil (or any pencil of constant double ratio) whose sides pass through four fixed points (two of these correspond to the circular points) is a conic section passing through the four fixed points.»

8. *Relations to Analytic and Non-Euclidean Geometry.*—The fact that in metrical geometry the point 1 upon a line is half-way between the points 0 and 2 furnishes a clue for constructing a projective scale purely by harmonic constructions. Let three points A, B, C be arbitrarily assigned the numbers 0, 1, ∞. By finding the fourth harmonic to 0 with respect to 1 and ∞, a point is constructed to which the number 2 is assigned. In like manner all the positive integers may be located. The negative integer $-N$ is assigned to the point harmonically situated with respect to $+N$ and the pair 0, ∞. By projecting 0, N, ∞ into 0, 1, ∞ the points $1/N$, $2/N$, . . . can be located. Thus all the rational numbers are assigned to points on a line. By use of F. P. 8 it may be shown that to each point of the line corresponds a number rational or irrational or ∞, and to each number corresponds just one point.

To obtain a system of coördinates for the plane, assume two lines in the plane. Mark their intersection as 0 and upon each of them mark arbitrarily the points 1, ∞. Then to

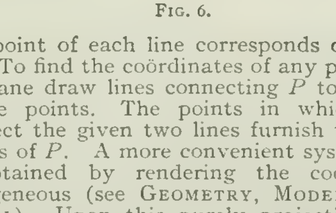

FIG. 6.

each point of each line corresponds one number. To find the coördinates of any point P of the plane draw lines connecting P to the two infinite points. The points in which these intersect the given two lines furnish the coördinates of P. A more convenient system may be obtained by rendering the coördinates homogeneous (see GEOMETRY, MODERN ANALYTICAL). Upon this purely projective basis all analytical geometry may be built up. The system is evidently that which is obtained by projecting the ordinary Cartesian system of coördinate axes into the system here assumed. In practically all treatises upon analytical geometry the coördinates are introduced as metrical quantities and are only later proved to be truly projective. Analytical projective geometry is closely related to Invariants and Covariants (q.v.), Geometry of Hyperspaces (q.v.), Modern Analytical Geometry (q.v.),

Higher Plane Curves (q.v.), and Determinants (q.v.).

Projective geometry includes in itself not only metrical geometry, but the ordinary non-Euclidean geometries as well. This is seen from examining the fundamental propositions upon which those geometries are based, or, better, by following the analytical method of A. Cayley (q.v.), and defining distance in the various geometries as the logarithm of a double ratio. (See GEOMETRY, NON-EUCLIDEAN.)

9. *New Problems and Bibliography.*—It may well be said that pure projective geometry, which rose with von Staudt in 1847 and was carried on by numerous investigators during the next fifty years, has now reached a stage that is near finality, and that new problems are likely to be on neighboring fields. Thus at present there is a great deal of work on the foundations of mathematics. For pure projective geometry this means the determination of one or more sets of postulates and fundamental concepts which shall be 1° projective, 2° complete, 3° compatible, 4° independent and irreducible, and 5° as nearly self-dual as possible. This problem is not yet settled in a wholly satisfactory manner, despite the researches of Pieri, Schur, Moore, and Veblen. The fundamental propositions assumed in earlier sections are far from satisfying rigorously all these conditions. They are, however, sufficiently good for most purposes.

The theory of involutory projectivities has been satisfactorily developed as far as its application to transformations which leave a quadratic form fixed is concerned, but for the general case there remains much to be done. And so with many other special problems which might be enumerated.

Of late Wilczynski has been developing a projective theory of curves and surfaces which, though not wholly in touch with pure projective geometry, promises valuable additions to the subject.

A complete bibliography of memoirs and books may be found in the historical account of the subject by Ernst Kötter, 'Die Entwickelung der synthetischen Geometrie,' the first volume of which appeared in 1901. The work is not yet complete. The same is true of the 'Encyclopedie der mathematischen Wissenschaften' (vol. III, Pt. 1). The following text-books may be cited: von Staudt, 'Geometrie der Lage' (1847); 'Beiträge zur Geometrie der Lage' (1856–1860); Reye, 'Geometrie der Lage' (1892–1899), partly translated by Holgate, 'Geometry of Position' (1898); Böger, 'Geometrie der Lage' (1900); Sannia, 'Geometria proiettiva' (1895); Enriques, 'Lezioni di Geometria proiettiva' (1898), translated into German, 'Vorlesungen über projektive Geometrie' (1903). From the older standpoint: Steiner, 'Vorlesungen über synthetische Geometrie' (1898); Cremona, 'Projective Geometry' (1893, translated by Leudersdorf); Poncelet, 'Traité des Projections' (1866); Duporcq, 'Premiers Principes de Géométrie modernes' (1899).

EDWIN BIDWELL WILSON,
Instructor in Mathematics, Yale University.

Geophagy, jē-ŏf'ajĭ, **Geophagism,** or **Dirt-eating,** the practice of eating some kind of earthy matter, as clay or chalk, common among uncivilized peoples, such as the South American Ottamacs, the Indians of the Hudson Bay country, the West Indian blacks, the negroes in some of the United States, and among the less civilized whites in the mountain districts of Tennessee and Kentucky. In some cases it is probably used to allay hunger, but it is also practised where the supply of food is sufficient. Among chlorotic young women a similarly depraved appetite is not uncommon.

George, surnamed «THE BEARDED,» duke of Saxony: b. 27 Aug. 1741; d. 17 April 1539. He was the son of Albert the Brave, the founder of the Albertine line of Saxony, and succeeded, in 1500, to the hereditary dominions of the Albertine house. Later on he became involved in the turmoils of the Reformation Period. He was not at first wholly hostile to reform, but thought that it could be better effected by means of papal edicts than by the revolt of Luther. Accordingly he became embittered by the uncompromising tone of Luther's later writings, and endeavored to suppress the Reformation in his dominions by violent measures. These, however, were unsuccessful, and in 1539, on the accession of his brother Henry, who was a Protestant, the Reformation was introduced into the dominions of the Albertine house of Saxony.

George, Saint, the especial patron of chivalry, and tutelary saint of England: d. Nicomedia 23 April 303. Though venerated both in the Eastern and Western Churches, his history is extremely obscure, the extant accounts containing very much less history than legend. The story in the 'Acta Sanctorum' ('Deeds of the Saints') is that he was born of noble Christian parents in Cappadocia, became a distinguished soldier, and after testifying to his faith before Diocletian, was tortured and put to death He was adopted by the Genoese as their patron saint, and in 1222 the Council of Oxford ordered that his day (the 23d of April) should be observed as a national holiday in England. In 1344 an order was instituted in his honor by Edward III., and in 1350 this was made the Order of the Garter, of which accordingly Saint George is the patron.

George I. (GEORGE LOUIS), king of Great Britain, and Elector of Hanover: b. Hanover, Germany, 28 March 1660; d. Osnabrück 11 June 1727. He was the son of the Elector Ernest Augustus, by Sophia, daughter of Frederick, elector palatine, and granddaughter to James I. In 1682 he married his cousin, Sophia Dorothea, daughter of the Duke of Celle. The union was not a happy one. George I. was both a faithless and a jealous husband, and when his wife, who was guilty of some imprudences, brought on herself the suspicion of carrying on an illicit intrigue with Count Königsmark, he caused her to be imprisoned, and kept her in confinement for the rest of her life. The offspring of the marriage were George, Prince of Wales, afterward George II., and Sophia, the mother of Frederick the Great. In 1698 he succeeded to the electorate, and in this succession was joined in the alliance against France. The command of the imperial army was conferred upon him in 1707, but owing to jealousies among his confederates he resigned the command at the end of three campaigns. At the Peace of Rastadt Louis XIV. recognized the electoral dignity in

the house of Lunenburg, as he had already by the Treaty of Utrecht recognized the succession of the same house to the throne of Great Britain, which event took place on the death of Anne in 1714, when the elector was in the 55th year of his age. His reign in England was disturbed first by a rising of the Scottish Jacobites in favor of the son of James II., and afterward by wars with Spain, undertaken first in conjunction with Holland and France (the Triple Alliance of 1717), afterward in addition with Austria (the Quadruple Alliance of 1718), with the view of checking the schemes of the Spanish minister Alberoni. George I. was plain and simple in his taste and appearance; he possessed much natural prudence and good sense, and his management of his Germain dominions, to which he showed more attachment than to his English dominions, was able. See Coxe, 'Life of Walpole' (1808); Wright, 'England Under the House of Hanover' (1848); Thackeray, 'The Four Georges' (1860).

George II. (George Augustus), king of Great Britain, son of George I.: b. Hanover 10 Nov. 1683; d. London 25 Oct. 1760. He married in 1705 Wilhelmina Carolina of Brandenburg-Anspach. In 1708, then only electoral prince of Hanover, he distinguished himself under the command of Marlborough. He came to England with his father at the accession of the latter, and was created Prince of Wales. He was made regent during the king's visit to the continent in 1716, but a political difference ensuing, he lived some time estranged from the court. This breach was finally accommodated, and in 1727 he succeeded to the throne. He inherited in full force the predilection of George I. for Germany; and the same system of politics and the same ministers continued to govern the nation after his accession as before it. In the earlier part of his reign, during the greater part of the ministry of Walpole, the neutrality of England was preserved during the wars on the continent. In 1739 the depredations committed by the Spaniards in America on the commerce of England led to war, which brought about the resignation of Walpole in 1742. England next took part in the war of the Austrian Succession, in which George II. himself shared, being present at the battle of Dettingen, in 1743. His reign is also memorable on account of the second Jacobite rising in Scotland in 1745–6, headed by Prince Charles Edward. In 1755 the disputes between Great Britain and France in relation to their respective boundaries in Canada produced hostilities in that country, and an open war between the two nations the following year. The events of this war, in which the principal powers of Europe became engaged, raised Great Britain, under the able auspices of Pitt (first earl of Chatham), to the pinnacle of power. George II. was a prince of very moderate abilities, parsimonious, and wholly regardless of science or literature; hasty and obstinate, but honest and open in his disposition. His queen, the cultivated and well-informed Caroline, acquired a great ascendency over him, which did not, however, prevent some of the irregular attachments so common with royalty. See Hervey, 'Memoirs of the Reign of George II.' (1854); Walpole, 'Memoirs of the Last Ten Years of the Reign of George II.' (1822–46); Schmucker, 'History of the Four Georges' (1860); Thackeray, 'The Four Georges' (1860); Jesse, 'Memoirs of the Court of England from the Revolution of 1688 to the Death of George II.' (1843).

George III., king of Great Britain: b. London 4 June 1738; d. Windsor 29 Jan. 1820. He was the eldest son of Frederick, Prince of Wales, by the Princess Augusta of Saxe-Gotha. On the death of his father in 1751, his education was entrusted to the Earl of Harcourt and the Bishop of Norwich; but the formation of his opinions and character seems to have been materially influenced by the maternal ascendency of the princess dowager, who was principally guided by the counsels of the Earl of Bute. George III., who had been previously created Prince of Wales, ascended the throne on the demise of his grandfather, George II., being then in his 23d year. In the following year he married the Princess Charlotte Sophia of Mecklenburg-Strelitz, a union which in its result operated materially on the domestic character of this reign. In 1763 the Seven Years' war was concluded by the Peace of Paris under the ministry of Lord Bute. In 1764 Mr. George Grenville, who had become premier by the retirement of the Earl of Bute, began those measures in relation to the American colonies, the consequences of which proved so momentous; and the Stamp Act was passed the following year. About the same time, in consequence of some appearances of the mental derangement of the king, a bill was passed to enable his majesty to appoint the queen, or any of the royal family residing in England, guardian to his successor, and regent of the kingdom. In 1766 the Rockingham administration repealed the American Stamp Act; at the same time passing a declaratory act asserting the right of taxing the colonies. The Rockingham cabinet was dissolved 30 July 1766, and succeeded by one formed by Pitt, now earl of Chatham. In 1768 Lord Chatham, disgusted with the conduct of his colleagues, resigned the privy-seal, and was succeeded by Lord Bristol. The same year was distinguished by the return of John Wilkes for Middlesex, and the popular tumults attendant upon his imprisonment and outlawry. In 1773 the discontents in America burst into an open flame, and a royal message, in the commencement of the session of 1774, called on Parliament to maintain the English supremacy. Notwithstanding the subsequent loss of an empire, George III., by the steadiness with which he put down the coalition administration, acquired a degree of popularity which never afterward entirely deserted him. The smooth course of the early years of the administration of Pitt materially added to this disposition, which exhibited itself very strongly when the constitutional malady of the king again displayed itself in 1789, and still more upon his subsequent recovery. In reference to the French Revolution, and the important contests which arose out of it, it is sufficient to remark that George III. zealously coincided in the policy adopted by his administration. A similar observation will apply to the domestic, and Irish and Indian policy of the Pitt cabinet; as also to the transactions connected with the Irish rebellion. George III. was immovable in his opposition to the demands of the Irish Catholics, and, seconded by the influence of the Church and the popular feeling, was enabled to eject

the Fox and Grenville administration, which succeeded on the death of Pitt. The proceedings of the Perceval administration, until the final retirement of the king in 1810, need not be detailed here; while the insanity of the monarch renders the interval which elapsed from his retirement to his death a blank in his biography. George III. possessed personal courage and steadiness of character in a high degree. Of a plain, sound, but not enlarged understanding, he acted upon his convictions with sincerity. His tastes and amusements were plain and practical. Literature and the fine arts engrossed but a small share of his attention, and hunting, agriculture, mechanical contrivances, and domestic intercourse, seem to have chiefly occupied his leisure. Religious, moral, and temperate, the decorum of his private life was always exemplary. His deportment as a father and a husband, according strictly with the national notions of propriety, rendered him and the queen a constant theme of praise; and the throne was regarded as a pattern in respect to the conjugal duties. See Walpole, 'Memoirs of the Reign of George III.' (1894); Massey, 'History of England During the Reign of George III.' (1855).

George IV. (George Augustus Frederick), king of England: b. London 12 Aug. 1762; d. Windsor 26 June 1830. He was the son of George III. and the Princess Charlotte of Mecklenburg-Strelitz. His dissipated life, his extravagance, his supposed marriage with a Roman Catholic, Mrs. Fitzherbert, and his connection with the most prominent members of the Opposition, alienated from him the affection of his father and the esteem of the nation. In 1795 he consented, on condition of the payment of his debts, to marry the Princess Caroline of Brunswick, but he soon began to treat her with neglect, and after the birth of their daughter, Charlotte Augusta, abandoned her. (See Caroline Amelia Elizabeth.) On 3 Feb. 1811, he was appointed regent, with limited powers, on account of the king being attacked the previous year by a repetition of the mental malady to which he was subject. The Whigs, his former friends, now hoped to come into office, but the prince showed a sudden change of sentiments, and maintained the Perceval ministry in power. The distress caused by the interruption of the demand for manufactures, and the high price of the means of subsistence after the general peace of 1815, occasioned great discontent among the people, and the violent measures adopted by the government increased the unpopularity of the regent, upon whose life an attempt was made in 1817 when he was going to open the session of Parliament. In 1820 he became king, on the death of George III. In February 1827, Canning became head of the government. The most important event after his attaining the throne was the passing of the Catholic Emancipation Act, by the Wellington ministry, in 1829. George IV. left no descendants, his only daughter, the Princess Charlotte, wife of Leopold of Saxe-Coburg, having died childless in 1817. He was therefore succeeded by his brother William, Duke of Clarence (William IV.). See McCarthey, 'History of the Four Georges and of William IV.' (1884-1901); Thackeray, 'The Four Georges' (1860); Cooly, 'Life of George IV.' (1830); Lady Bury, 'Diary of the Times of George IV.' (1838).

George I., king of Greece, with the title, King of the Hellenes: b. Copenhagen 24 Dec. 1845. He was second son of the king of Denmark. In 1863 he was elected king by the Greek National Assembly. In 1867 he married the Princess Olga, a niece of the Russian czar. His conduct as a constitutional monarch has been always correct and regular, and he won the popular sympathies by the efforts he made on behalf of the expansion of Greek nationality. His children have been bred in the Greek faith.

George V., king of Hanover: b. Berlin 27 May 1819; d. 12 June 1878. He was son of Ernest Augustus. He ascended the throne of Hanover in 1851; in the war between Prussia and Austria in 1866 took side with the latter, and in the same year was removed by Prussia, which annexed the kingdom on 20 September. As ex-king he assumed the titles of Duke of Cumberland and Teviotdale (Great Britain) and Earl of Armagh (Ireland).

George II., duke of Saxe-Meiningen: b. Meiningen 2 April 1826. He was educated at Bonn, received the commission of major in the Prussian cuirassier-guards, succeeded to power upon the abdication of Duke Bernhard, his father, in 1866, and served in the Franco-German war as Prussian general of infantry. Assisted by the manager Cronegk he did much to improve the artistic presentation of German drama.

George, prince of Denmark: b. 1653; d. 1708. He was son of King Frederick III., and husband of Queen Anne of England. He sided with William of Orange in the Revolution of 1688, and received the title of Duke of Cumberland. Later he became grand-admiral. From his favorite exclamation he was jocosely known as *Est-il-possible*.

George, Greek prince, 2d son of George I., king of the Hellenes: b. Corfu, Ionian Islands, 25 June 1869. He was appointed lieutenant in the Greek navy 19 July 1889. While traveling in Japan, in 1891, with his cousin, the grand-duke (afterward Nicholas II.) of Russia, he rescued the latter from death at the hands of a religious fanatic. He was appointed high commissioner in Crete in December 1898.

George, duke of Clarence, and brother of Edward IV., king of England; d. 1478. He espoused the cause of Henry VI. and his queen, Margaret of Anjou, against his brother and sovereign. Some years afterward he was accused of having sought the hand of Mary, duchess of Burgundy. He subsequently married a daughter of the Earl of Warwick (the "king-maker"), and joined him in his revolt against the royal authority. Being taken prisoner, he was condemned to death. The unfortunate prince, being allowed to choose the mode of his death, is said to have drowned himself in a butt of Malmsey wine.

George, Ernest, English architect: b. London 13 June 1839. He studied at the Royal Academy and received the queen's gold medal of the Royal Institute of British Architects in 1896. He has conducted extensive restorations, etc., at Welbeck Abbey and has built various

country-seats and churches in Devon, Hertfordshire, and other parts of England.

George, Henry, American political economist: b. Philadelphia 2 Sept. 1839; d. New York 29 Oct. 1897. He made his way to California as a sailor in 1858, and worked there as a printer for several years, until he became a reporter for the San Francisco *Times,* and in 1867 the editor of the same paper. In 1871 he published 'Our Land and Land Policy' in which he advocated the single tax theory, later developed more fully in 'Progress and Poverty' (1879). In this latter work, he not only explained his policy of land taxation (see SINGLE TAX), but also attacked the doctrine of Malthus (q.v.), and the "wages fund" theory, advancing the theory that the wages of labor are paid out of the value that the laborer creates, not from a "fund" of capital. The book did not at once attract much attention, and was first widely noticed in England; later attaining great popularity in this country. George visited England in 1880-1, and on his return settled in New York, where he devoted his time to writing, and agitation and organization for the single tax movement. In 1886 he was nominated for mayor of New York by the United Labor party, but was defeated, though receiving over 67,000 votes. In 1897 he was again nominated for mayor and took an active part in the campaign, but died before election day. His works, besides those already mentioned, include: 'The Irish Land Question;' 'Social Problems' (1883); 'Property in Land;' 'The Condition of Labor;' 'Protection or Free Trade' (1886.

George, Hereford B., English writer: b. Bath, Somerset, 1838. He was educated at Winchester and Oxford, was called to the Bar in 1864 but returned to Oxford in 1867, and was tutor at New College, Oxford, till 1891. He has published: 'The Oberland and Its Glaciers;' 'Genealogical Tales Illustrative of Modern History;' 'Battles of English History;' 'Napoleon's Invasion of Russia;' 'The Relations of Geography and History;' etc.

George, James Zachariah, American politician: b. Monroe County, Ga., 20 Oct. 1826; d. Mississippi City, Miss., 14 Aug. 1897. He fought in the ranks in the Mexican war, afterward studied law, became brigadier-general in the Confederate army during the Civil War, and in 1879-81 was chief justice of the supreme court of Mississippi. In 1880 he was elected to the United States Senate as a Democrat, and in 1886 and 1892 was re-elected. As a jurist he aided in drafting the present State Constitution of Mississippi, and in the Senate he was well known as an orator.

George, William Reuben, American philanthropist: b. West Dryden, N. Y., 4 June 1866. From 1880 he was in business employment in New York. His study of conditions among poor children resulted in the formation of the George Junior Republic (q.v.), of which he became director.

George Eliot. See ELIOT, GEORGE.

George Sand. See SAND, GEORGE.

George Junior Republic, the community established (1895) near Freeville, N. Y., by W. R. George (q.v.) as a method of reform in the treatment of dependent and delinquent children. The organization is that of a miniature republic, with a constitution and machinery of government based on that of the United States. Originally the founder was president with other adults in the more important posts, but from 1896 all offices have been held by citizens. Each citizen may work for the founder or for other citizens who contract for labor. All purchase is made by the Republic's aluminum coin, later redeemed by United States currency. School is held, and farming, carpentry, printing, care of the establishment, dressmaking, domestic service, and cookery are the other activities followed. The entrance age is from 12 to 18.

George, Lake, in the eastern part of the State of New York, is one of the most beautiful, noted, and picturesque lakes in the world. It is fed mostly by ice cold springs, there being less than half a dozen living streams flowing into it. Its outlet is Lake Champlain in the Saint Lawrence river basin. It is the headwaters of one of the most noted of the Saint Lawrence valleys. It narrows at its outlet and the waters enter Lake Champlain by a short creek, which has a descent of about 230 feet in a mile with a series of cascades and an abrupt fall of 30 feet at Ticonderoga. Its length is about 36 miles, and it is 346 feet above the sea, and at its headwaters it is 247 feet above Lake Champlain.

In 1609 Champlain sailed up the lake which bears his name, and Indians told him of the beautiful water called Andiatarocti (Place Where the Lake Contracts) but there is no record that he ever saw Lake George. Father Jogues, a Jesuit missionary, first saw the lake on 29 May 1646, and because it was the eve of Corpus Christi he called it Lac du St. Sacrament, or Lake of the Blessed Sacrament, a name which it retained until it was changed by Gen. William Johnson, 28 Aug. 1755, and given that of Lake George, after George II. The name "Horicon" given it by Cooper, is an historical fraud, the creation of the novelist's brain.

This lake is on the direct route of travel which was used in the early days of exploration and colonization in journeying to and from Canada and New York. It was on the Great War Trail of the Nations, and was in turn under the control of the French, the English, and the Colonists, while our country was in its formative stage. During the French and Indian War, forts were built at Carillon (Ticonderoga) by the French, and at the head of Lake George (Fort William Henry, Fort George, and Fort Gage) by the English. It has been the scene of numerous bloody contests, between the whites and the Indians, the French of Canada and the English of the colonies. The encounter known as the "Battle of Lake George" occurred 8 Sept. 1755, between the French and Algonquins under Baron Dieskau, and the English and Iroquois under Sir William Johnson, with an Indian chief, King Hendrick, in charge of the Indians. A monument commemorative of this battle was unveiled at Lake George 8 Sept. 1903. It consists of heroic figures of Sir William Johnson and Chief Hendrick, designed by Albert Weinert. The State of New York has purchased here a large tract of land, containing the battlegrounds and Fort George, the reservation being known as "Battle Park." A few miles to the south King Hendrick fell, while a monument marks the spot where Col. Ephriam

Williams, founder of Williams College, met his death. Among the more important were the siege by Montcalm, capture and massacre at Fort William Henry 9 Aug. 1757; the gathering of Lord Abercrombie's great army, its defeat, and death of Lord Howe at Ticonderoga, 5-8 July 1758; the building of Fort George, advance down the lake and capture of Fort Ticonderoga by Lord Amherst, July 1759; capture of Fort Ticonderoga by Ethan Allen, May 1775; removal of guns and stores over the lake, winter of 1775-76 to Boston by Col. Henry Knox; and occupancy by American forces, spring 1776, followed by devastating smallpox epidemic; seizure by General Burgoyne, summer 1777; unsuccessful attack on Diamond Island by Americans under Colonel Brown on English forces, 22 Sept. 1777; capture of Fort George by Major Christopher Carlton (English) Oct. 1780; visit of General Washington and staff, July 1783.

The State has bountifully stocked its waters with fish. Deer, black bear, rabbits, partridges, foxes, minks, and rattlesnakes are to be found among its mountains, and ducks, eagles, gulls, and all kinds of wild birds fly above its waters. The lake is surrounded by mountains, the most striking of which are Prospect (1,800 ft.), Buck (2,000 ft.), Tongue, with its succession of mounts, Erebus, Shelving Rock, Black (2,315 ft.), Anthony's Nose, named after Anthony Wayne, and Rogers' Slide, after the fabled exploit of Rogers the Ranger, in 1757-58.

Lake George has more than 200 islands, among the largest of which are Long and Big Burnt Islands; Dome Island is the highest, Green Island is the most beautiful, and Diamond the most celebrated historically and sentimentally; Tea — so-called from «a tea house» erected there in 1828; Recluse and Floating Battery, occupied by Abercrombie 1758; Fourteen Mile, used by Burgoyne's forces for camping purposes; Harbor Islands, scene of a bloody conflict 25 July 1757 between French and Indians and English; and Prisoners', at foot of lake, used by the French as a place of confinement for captives. «The Narrows,» half way down, are narro passages in the lake, filled with large and small islands, known generally as the «Hundred Islands.»

There are many indentations in the lake line, some forming large bays. The best known are Dunham's, Kattskill, Bolton, Northwest, in itself a considerable lake; Fourteen Mile, and Paradise, the most beautiful bay in the world. The lake is well served by three fine steamers run in connection with the D. & H. Railroad and Champlain Transportation Line. The principal villages on the lake are — Lake George, at the head, located in the town of Caldwell (pop. [1900] 534); Bolton Landing, and Hague, near which are the Dixon graphite mines, the largest of their kind in existence. The ruins of Fort Ticonderoga (q.v.) are not far from the foot of the lake. Geologically, Lake George is thought to be a formation of the glacial age. To the mineralogical expert specimens of value are readily accessible in the surrounding mountains. Garnets, resinites, cocolite, pyroxene, sphene, graphite, and tourmaline are found at Rogers' Slide; feldspar, hermatite at or near Anthony's Nose; while the beach sands contain powdered garnet, amethyst, crystal quartz, magnetic sand, and epidote; on Diamond Island are found quartz crystals; gold in nonpaying quantities has also been discovered.

James A. Holden.

George, Order of St. See Garter, Order of the; Orders (Royal): *Russia, Bavaria, Hanover, Sicily, Great Britain.*

Georgetown, capital of British Guiana, situated on the eastern side of the Demarara River, at its mouth, with the Caribbean Sea for a second frontage. The city covers an area of 1,200 acres. Nearly every building is isolated from its neighbor and surrounded by palms, shrubs, or forest trees. The streets cross each other at right angles; those which run north and south in some cases have long canals in the centre, beyond which are the roadways — the width of such streets being more than 100 feet. On Main (or High) street are situated the town-hall, Victoria law courts, police magistrate's office, Colonial Bank, Presbyterian Church, Portuguese Roman Catholic Church, and the Methodist Church. The public buildings, where the Court of Policy sits, and the Anglican Cathedral are also in this section. Another fine street is the Brick Dam, the two rows of houses in which constituted the entire town of Stabroek before the colony was captured by the British. The finest building in the colony, the Roman Catholic Cathedral, stands a short distance east of this street. The Royal Mail Company, with its fortnightly mail service, makes the port of Georgetown a terminus; boats of the French Compagnie Generale Transatlantique call monthly on the way to Cayenne; the Dutch Mail does the same when going to Surinam; and steamers of a Canadian line also call every fourth week. Vessels drawing more than 20 feet cannot cross the bar at the mouth of the river, and those of even lighter draught are obliged to wait for high water. A line of steamers subsidized by the government makes daily trips from Georgetown to Essequebo; three times a week a steamer runs to Berbice; twice a week up the Demarara and Berbice rivers; and there is fortnightly communication by boat with Morawhanna, the capital of the northwestern district. A railway connects Georgetown with Mahaica, on the east coast. The West India & Panama Telegraph Company also puts the city and colony in communication with other countries. There are good street-car and telephone services. The city water, brought from creeks 20 miles distant through the Lamah Canal, is chiefly valuable in case of fire; it is not sufficiently pure for household use. The city is lighted by gas and electricity. Municipal affairs are managed by a mayor and town council. The value of real property is nearly $8,000,000; the portion held by Europeans and creoles (other than Portuguese) being valued at $4,611,575; the portion held by Portuguese at $1,938,370; by East Indians, $101,930; and by Chinese, $45,750. The tax-rate is usually 2 per cent per annum on the appraised value of private property. There is a well-equipped and trained fire brigade. Among the important institutions are the Royal Agricultural and Commercial Society, which has a library of over 17,000 volumes, and maintains reading-rooms, etc.; the Institute of Mines and Forests, and the Chamber of Commerce. Of the newspapers, one is

issued daily, and a number weekly, bi-weekly or tri-weekly. The port is regarded as healthy. There were two or three severe attacks of yellow fever half a century ago; but since that time the drainage has been improved, and the neighborhood of the wharves kept clean, and during the past 50 years only one serious outbreak has occurred. The number of inhabitants is given as 53,176. (See GUIANA, BRITISH.) Consult Rodway, 'Handbook of British Guiana.'

MARRION WILCOX,
Authority on Latin-America.

Georgetown, Col., a town and the county-seat of Clear Creek County; situated, at an altitude of 8,475 feet, in a picturesque valley in the heart of the Rocky Mountains, 52 miles west of Denver on Clear Creek and the Colorado & Southern railway. It is the centre of an important silver district, and has also important gold-mining interests. There are several public parks, and gas, water, and electric-light plants. Pop. (1900) 1,418.

Georgetown, Del., a town and the county-seat of Sussex County, 40 miles south by east of Dover; on the Philadelphia, Wilmington & Baltimore railway. It is situated in an agricultural section. The chief interest is the canning industry. Pop. (1890) 1,353; (1900) 1,658.

Georgetown, D. C., at one time a town in the District of Columbia; now included within the limits of Washington (q.v.), and sometimes called West Washington. It was at the head of Potomac navigation, and the port of entry for the District of Columbia.

Georgetown, Ky., a city and the county-seat of Scott County, 12 miles north of Lexington and 20 miles east of Frankfort; on the Frankfort & C., the Cincinnati, N. O. & T. P., and the Louisville S. R.R.'s. It is in the heart of the "blue grass" region, and the centre of an important stock-raising and agricultural district. Flouring-mills, brick-works, and other industries are also located here. Georgetown College (q.v.) is here situated. The "Royal Spring," which rises in the centre of Georgetown and furnishes about 200,000 gallons of water per hour, supplies the municipal water plant and affords the power for the street railway, an ice plant, a flour mill, and other establishments. Georgetown was settled in 1776, incorporated in 1790, and received its charter in 1894. The government is administered by a mayor, chosen for four years, and municipal council, elected on a general ticket. Pop. (1900) 3,823.

Georgetown, Ohio, a village and the county-seat of Brown County, 42 miles east by south of Cincinnati and 7 miles north of the Ohio River; on White Oak Creek and the Cincinnati, Georgetown & Portsmouth railway. It is the centre of an agricultural region, the growing of tobacco being an especially important industry. There are also some manufactures, and blue limestone is quarried in the vicinity. Pop. (1900) 1,529.

Georgetown, Ontario, a town of Halton County, 25 miles west of Toronto; on Credit River and the Grand Trunk railway. The water-power is excellent. There are paper-mills, knitting-machine manufactories, and knitting and woolen factories. Pop. (1901) 1,313.

Georgetown, P. E. I., town and port on the eastern coast; by rail 39 miles east of Charlottetown. It is the chief winter port of the island. Pop. about 1,500.

Georgetown, S. C., a city and the county-seat of Georgetown County, about 55 miles northeast of Charleston; at the head of Winyah Bay and on the Georgetown & Western railway. It is a port of entry and a seaport of considerable importance, being the central market for an excellent agricultural region whose rivers, with a total navigable distance of 1,000 miles, empty into Winyah Bay. There are exports of rice, pine lumber, turpentine, fish, cotton, shingles, and other commodities. Georgetown was first settled about 1700 and was incorporated in 1805. The Marquis de Lafayette landed here at the beginning of his first visit to the United States (1784). The government is by a mayor, biennially elected, and a municipal council, chosen at large. Pop. (1900) 4,138.

Georgetown, Tex., a city and the county-seat of Williamson County, 30 miles north of Austin; on the San Gabriel River and a branch of the International & Great Northern railway. The surrounding region is an agricultural one. Georgetown has cotton-gins, cottonseed-oil mills, and planing-mills, and manufactories of plows, ice, harness, and woodwork. Here are located mineral springs whose waters are similar to those of the well-known springs at Karlsbad, Germany. Georgetown is also the seat of Southwestern University, an institution of the Methodist Episcopal Church, South, founded in 1873. It was settled in 1854, incorporated in 1874, and is governed by a mayor and council, biennially chosen. Pop. (1900) 2,790.

Georgetown College, Ky., a coeducational institution in Georgetown, founded in 1829 under the auspices of the Baptist Church; reported at the close of 1900: Professors and instructors, 19; students, 360; volumes in the library, 12,000; productive funds, $235,000; grounds and buildings valued at $194,000; income, $23,500; number of graduates, 580.

Georgetown University, D. C., an institution of higher education, under the direction of the Roman Catholic Church. The plan of the institution was undertaken as early as 1785 by the Rev. John Carroll, later first archbishop of Baltimore. In 1786 the corporation of clergymen in the chapter held at Whitemarsh, Md., adopted a series of resolutions directing the establishment of the institution and the erection of its first building. The year 1789 is generally considered the year of the foundation of the university, though students were not received until 1791. Upon the reorganization of the Society of Jesus in Maryland in 1805, the Georgetown College, as it was then called, was transferred to that society, under whose direction it still remains. In 1815 the university was empowered by act of Congress to confer any degree in the arts, sciences, and liberal professions which are conferred in other colleges and universities, and, in 1833, the Holy See empowered the university to confer, in the name of the Church, degrees in philosophy and theology. The university is composed of the college; the school of medicine, organized in 1851 and including since 1901 a school of dentistry;

and the school of law, organized in 1870. The college comprises three distinct departments, the graduate school, the undergraduate department, and the astronomical observatory. A preparatory department is also connected with the university. The teaching of the university is guided by the principles of the Ratio Studiorum, formulated by the Jesuit order, and a strict standard of scholarship is maintained. The facilities of the university include the Coleman Museum of Natural History, the Beauchamp Hughes Art Cabinet, and the Riggs Memorial Library. In 1904–5 there were reported a faculty of 140 and a student enrolment of 544.

George Washington University, The (formerly Columbian), a non-sectarian university with graduate departments for post-graduate and professional studies, and colleges conducting undergraduate, technical, and specialized work, located in Washington, D. C.; organized by special act of Congress in 1821 and by special amendatory acts of Congress. The University is divided first into departments for graduate work: a department of arts and sciences leading to the masters' degrees and the degree of doctor of philosophy; a department of politics and diplomacy, leading to the degrees of master of diplomacy and doctor of philosophy; a department of medicine comprising a four-year course, leading to the degree of doctor of medicine, and a three-year course leading to the degree of doctor of dental surgery; a department of law and jurisprudence with a three-year course leading to the degree of bachelor of laws, a fourth year additional leading to the degree of master of laws, a graduate course of one year leading to the degree of master of patent law, and a three-year course for graduate students in arts and law, leading to the degree of doctor of jurisprudence; Columbian College for undergraduates with courses leading to the degrees of bachelor of arts and bachelor of science; Washington College of Engineering, with courses for undergraduates leading to the degrees in engineering; and a division of architecture with courses for undergraduates and graduates leading to the degrees in architecture.

By an act of Congress amending the charter, approved 3 March 1905, colleges may be organized under the charter of the University upon independent financial foundations, but educationally a part of the University, for educational work in arts, sciences, liberal and technical knowledge. The University reported (1904–5): professors and instructors, 186; pupils, 1,408.

Otis D. Swett,
Registrar.

Georgia, in Europe (by the Russians called Grusia, by the natives Karthli), formerly a kingdom, but now included in the Russian government of Tiflis and Kutais, though the name is sometimes loosely employed to designate a much larger portion of the territory possessed by Russia south of the Caucasus. Area, in the latter sense, about 34,000 square miles; of Georgia proper, about 15,000 square miles; pop. 2,110,000. The history of the Georgians first becomes trustworthy about the time of Alexander the Great, to whom they became subject. After Alexander's death, in 323 B.C., they gained their independence under Pharnvas. The country was then governed by various dynasties of kings. Christianity was introduced toward the close of the 4th century; soon after the death of Mohammed, numerous followers of his entered the country and compelled the inhabitants to accept Islam. In the 11th century Georgia was twice invaded by the Seljuk Turks, and in the 13th, after widespread devastation, was captured by the Mongols under Timur. The Mongols were expelled in 1403 by George VII. In the 16th and 18th centuries Georgia was harried by the Persians, and at the same time the Turks were continually making encroachments. Aga Mohammed Shah in 1795 razed Tiflis to the ground, the king, Heraclius II., abandoning all resistance and taking refuge in the mountain fastnesses. In 1799 George XIII. formally resigned the crown in favor of the Emperor Paul of Russia, and in 1801 Russia annexed the country. Consult: Brosset, 'Eléments de la Langue Georgienne' (1837); Chubinov, 'Russian-Georgian Dictionary' (1846; new ed. 1886); Leist, 'Georgische Dichter Verdeutscht' (1887); Wardrop, 'The Kingdom of Georgia' (1888). See Georgian.

Georgia, the last settled of the 13 original States of the American Union; bounded on the north by North Carolina and Tennessee, on the northeast by South Carolina, on the east by South Carolina and the Atlantic Ocean, on the south by Florida, and on the west by Alabama; capital, Atlanta; area 59,475 square miles, of which 495 are water. Pop. (1900) 2,216,331, of which the white population numbers 1,181,109 and the colored 1,034,998.

Topography.— The northeastern part of Georgia is traversed by that part of the Appalachian chain of mountains known as the Blue Ridge, which in Georgia has an altitude of from 3,000 to 5,000 feet above sea-level. After running one third the distance across the State, it terminates abruptly, but appears again in short ranges and detached peaks. Northwest Georgia, the limestone region embracing about 3,600 square miles, has an altitude ranging from between 600 and 700 to 2,500 feet above sea-level. About 6,000 square miles of northern Georgia are above the altitude of 1,000 feet. About 20 miles to the west of the Blue Ridge lies the Cohutta Range, a continuation of the range known in Tennessee as the Unaka. The Cohutta has an altitude of 3,000 feet above sea-level with an abrupt escarpment toward the valley of the Oostenaula on the west, and then continues into Alabama in a low elevation called Dugover Mountain. To the northwest are Lookout and Sand Mountain ranges, which with their table-lands constitute a part of the Alleghany range, which, like the Blue Ridge, belongs to the great Appalachian system.

High Point, the loftiest part of Lookout Mountain, has an elevation of 2,408 feet. Its northeastern spur, called Pigeon Mountain, has an elevation of from 1,800 to 2,000 feet above the sea, its highest point rising to 2,331 feet. Another spur of Lookout, called Round Mountain, has an elevation of over 2,200 feet. Taylor's Ridge and its prolongation, called the White Oak Mountains, rise to an elevation of from 1,300 to 1,500 feet above sea-level. A little farther south, Rocky Face Ridge, with an elevation of from 1,500 to 1,700 feet, forms the

eastern watershed of Chickamauga Creek (or river, as it is sometimes called), which flows through the valley at an elevation of 900 feet above the sea. There are several detached peaks, among which the most noted are Pine, Lost, and Kennesaw Mountains, the last named with its double peak rising to the height of 1,809 feet. In De Kalb County, 14 miles east of the city of Atlanta, in a comparatively level country, Stone Mountain, a vast mass of granite, rises to the height of 1,686 feet.

One of the most prominent features of northeast Georgia is the Blue Ridge chain of mountains, already mentioned. Some of the peaks of this chain rise to an elevation of 5,000 feet. The following is a list of the most noted of the mountain peaks of Georgia with their height above the level of the sea: Sitting Bull (middle summit of Nantahela) in Towns County, 5,046 feet; Mona (east summit of Nantahela) 5,039 feet; Enota in Towns County, 4,797 feet; Rabun Bald, in Rabun County, 4,718 feet; Blood, in Union County, 4,468 feet; Tray, in Habersham County, 4,403 feet; Cohutta, in Fannin County, 4,155 feet; Dome, in Towns County, 4,042 feet; Grassy, in Pickens County, 3,290 feet; Tallulah, in Habersham County, 3,172 feet; Yona, in White County, 3,167 feet. In all the mountain section of Georgia are charming valleys abounding in very productive lands. The most noted are Cedar, Texas, Broomtown, and Vann's valleys in northwest Georgia, and Nacoochee (Evening Star) and Santee valleys in the northeast section of the State. Among the interesting features of northwest Georgia are numerous caves. Hardin's Cave, near Kingston, has chambers 20 to 30 feet high. Middle Georgia is the most thickly settled section of the State. With the exception of two mountains, this region varies in altitude from 180 to 500 feet, and in a few instances to 1.000 feet. Lands too steep for the plow are seldom found in middle Georgia.

South Georgia embraces more than half the area of the State and extends from the southern limit of middle Georgia to Florida and the Atlantic coast. Its altitude ranges from 100 to 500 feet. About 3,000 square miles of the coastal region have an elevation of 100 feet.

Rivers.— The drainage system of Georgia comprises nine basins. The Tennessee basin is drained by tributaries of the Tennessee River. The Mobile basin is drained into the Gulf of Mexico by the Coosa and Tallapoosa rivers, and their tributaries. The Apalachicola basin is drained by the Chattahoochee and Flint rivers. These, uniting in the southwestern corner of Georgia, form the Apalachicola River which, flowing through Florida, empties into a bay of the same name, an arm of the Gulf of Mexico. The Altamaha basin is drained by the Oconee and Ocmulgee rivers, which empty into the Altamaha, flowing into the Atlantic Ocean. The Ogeechee basin is drained by the Ogeechee River into the Atlantic Ocean through Ossabaw Sound. The Savannah basin is drained by the Savannah River and its tributaries into the Atlantic Ocean. The Ocklockonee basin is drained by the river of that name into the Gulf of Mexico through Ocklockonee Bay. The Suwanee basin is drained by the river of that name into the Gulf of Mexico. Although the Suwanee runs for the greater part of its course through the State of Florida, it rises in southeast Georgia, and two of its main tributaries, the Allapaha and Withlacoochee rivers, are streams of south-central Georgia. The Satilla and St. Mary's basin is drained by the Satilla and St. Mary's rivers. The Satilla is the more northern and enters the Atlantic through St. Andrew's Sound. The St. Mary's enters the Atlantic Ocean through Cumberland Sound. Between these rivers lies the noted Okefinokee swamp. Its numerous large rivers furnish the State with excellent water transportation. Although the extensive railroad lines have built up in Georgia flourishing cities and towns remote from any water highway, yet those which are upon navigable streams enjoy the advantage of a competing water line. The Savannah is the most important river of Georgia for the reason that over 18 miles of its course is navigable for ocean vessels. The Savannah is navigable for river steamboats to Augusta, 230 miles to the north. The Chattahoochee is navigable for steamboats from Columbus to the Apalachicola and through that stream to the Gulf of Mexico. Through its several steamboat lines Columbus has a considerable river trade. The city of Rome in northwest Georgia has besides its several railroad lines a fine river trade through the Oostanaula and the Coosa. Steamboats carry to Rome the productions of the Coosa valley, lumber, iron, grain, and cotton, and the staple products of the Oostanaula valley. Albany, in southwest Georgia, enjoys an extensive steamboat traffic by the Flint River. The St. Mary's River is navigable for the largest vessels up to and beyond the town of that name, which is nine miles from the ocean. The Satilla and Ogeechee are each navigable for some distance, but their advantages have not been utilized to any considerable extent. Other navigable waters of Georgia are the inlets and sounds, flowing between the mainland and the islands that skirt the coast from the Savannah to the St. Mary's rivers. Through St. Simon's Sound the largest vessels pass up the Turtle River, a short but deep stream, to the city of Brunswick, the second in importance of the ports of Georgia, being, like Savannah, the centre of a fine fruit and trucking section. Every section of Georgia is drained by rivers of considerable size, and is consequently a splendid agricultural country. Its numerous navigable streams, supplementing its great railroad system, conspire to give its people unusual advantages for both internal and foreign commerce.

Climate.— Of nine climate belts in the United States eight are represented in Georgia. The lowest of these eight belts in mean annual temperature is below 40°, the highest between 70° and 75°. The climate of less than 40° mean annual temperature is found only on some of the mountain peaks. On the sides of these mountains below the summit the mean annual temperature is between 40° and 45°, corresponding with upper New England and New York and the mountain region of Virginia. There is a still larger climate zone of between 45° and 50° which corresponds with that to be found in portions of New York, Pennsylvania, and Ohio. The zone of between 50° and 55° embraces a narrow strip which runs northward through North Carolina and Virginia up to New Jersey. The zone between 55° and 60° of mean annual temperature contains an area two or

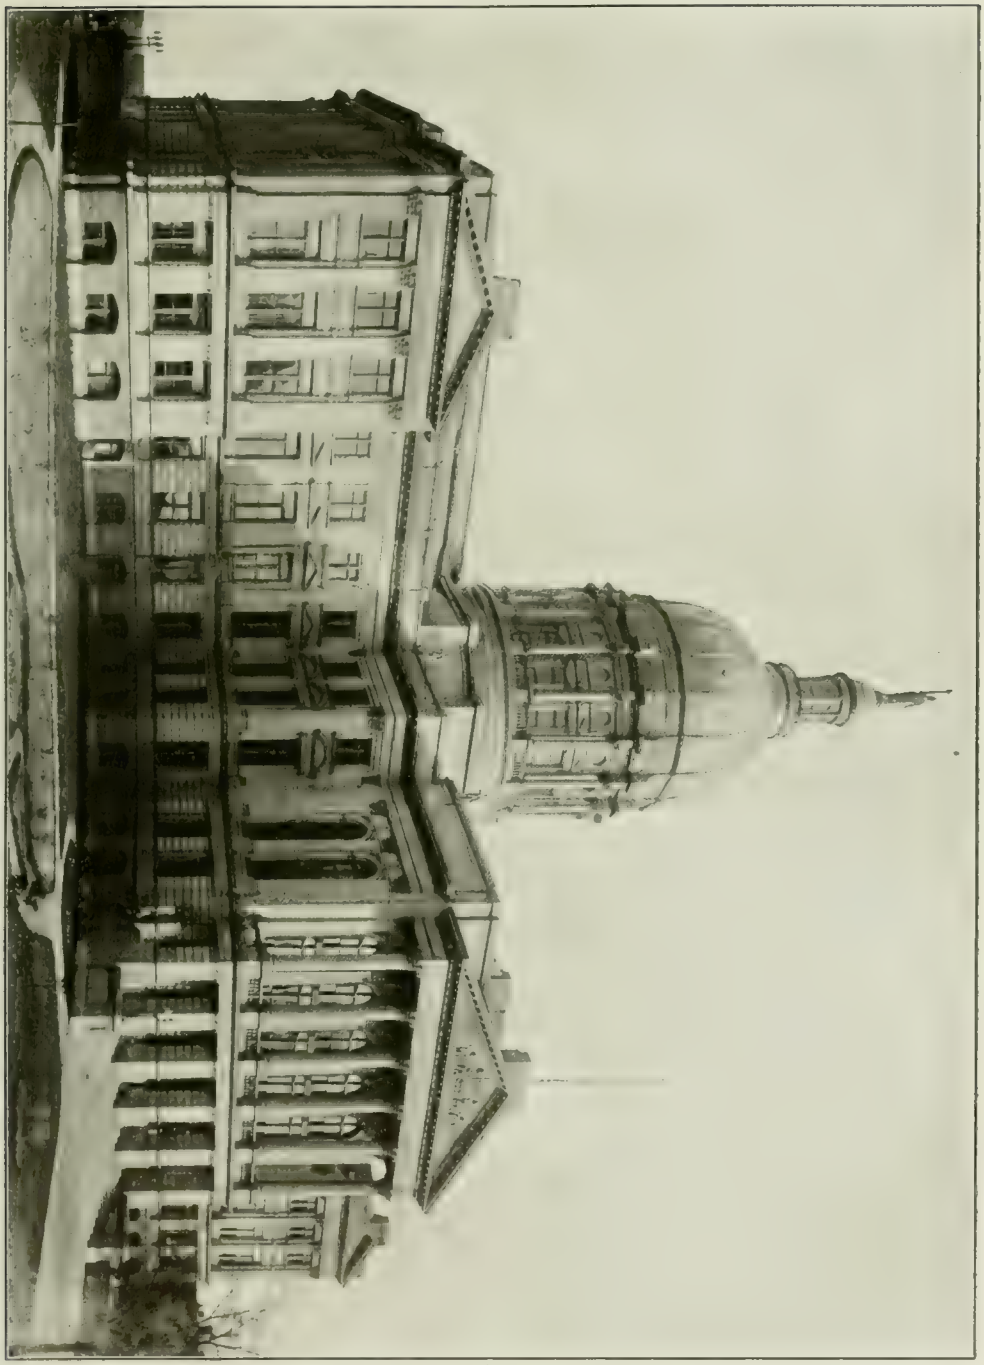
three times as large as all the preceding zones together and, passing through both Carolinas, ends in Virginia. The zone between 60° and 65° embraces nearly all of middle Georgia, corresponding with that of upper Alabama, Mississippi, Louisiana, Texas, West Tennessee, and Arkansas, and extends into Virginia. The mean annual temperatures at some of the important stations in this area are: Rome, 61.9; Gainesville, 61.3; Atlanta, 61.4; Carrollton, 62.; Athens, 63.; Augusta, 64.; LaGrange, 64.1; Thomson, 64.7.

The climate of southern Georgia is between 65° and 70° of mean annual temperature and corresponds with that of southern Texas, Louisiana, Mississippi, and upper Florida. At Macon it is 66.1°; Cuthbert, 68.1; Americus, 68.2; Brunswick, 68.7. Blackshear with 70.2° is the only station touching the zone between 70° and 75°. For the whole State the mean temperature for July is 81.8°. The isothermal line of 80°, July temperature, runs above Augusta and Macon to West Point. Above this line embracing the greater portions of north and middle Georgia the July temperature is between 75° and 80°. Below this line, embracing the greater part of East Georgia and nearly all of southeast and southwest Georgia the July temperature is between 80° and 85°. The climate of Atlanta, situated as it is on a ridge 1,050 feet above sea-level, corresponds with that of Washington, St. Louis, and Louisville, the winters being warmer and the summers cooler. Snow seldom falls in southern Georgia, and then rarely to a depth of more than two inches. In middle Georgia the fall of snow is a little more frequent and to a greater depth, while both its frequency and depth are greatly increased in the mountain region. The annual average rainfall of Georgia is 49.3 inches, the highest being at Rabun Gap, 71.7 inches, the lowest at Swainsboro, 39.4 inches. Atlanta's annual rainfall is 52.12 inches. The average for different sections of the State is: Middle Georgia, 49.7 inches; east Georgia, 41.4 inches, and northwest Georgia, 60.3 inches. The summer rainfall averages: For north Georgia, 13.6 inches; for southwest Georgia, 14.5 inches, and for the entire State, 13.4 inches. The summer rainfall averages at different localities: Rome, 10.2 inches; Atlanta, 10.8 inches; Rabun Gap, 15.4 inches; Americus, 16 inches; Brunswick, 16.6 inches.

Agriculture.— The northwestern section of Georgia presents a great variety of surface and soil. The slopes of the mountains and hills are well suited for the grazing of stock, and abundance of land, either rolling or entirely level in the valleys, is adapted to the raising of vegetables, fruits, corn, wheat, rye, oats, barley, buckwheat, cowpeas, clover, timothy, orchard grass, Bermuda, Johnson, crab, red top, and many other grasses useful for hay and pasturage. Cotton also is a profitable crop as far north as Floyd County, above which very little of this crop is raised. Some of the chief fruits are peaches, apples, pears, cherries, all kinds of berries and grapes of every variety. The forest timbers are oaks of several varieties, pines of two varieties, also the poplar, ash, beech, elm, chestnut, hickory, maple, walnut, iron wood, sugar berry, sycamore, sweet-gum, dogwood, persimmon, sassafras, wild cherry, rosebud, warhoo, cedar, and buckeye. In northeast Georgia but little over 12 per cent of the land is under cultivation, because this part of the State is thinly inhabited; but many of the tillable lands have a very rich, dark red soil. Little Tennessee valley in Rabun County and Nacoochee valley in White County are noted for fertility, bearing all kinds of crops, fruits, and grasses. About 75 per cent of the whole area known as middle Georgia is under cultivation. The central cotton region of the State includes the southern part of middle and large areas of southern Georgia. This region embraces the sand and pine hills belt, the red hills belt, and the yellow loam region. The first of these covers about 3,000 square miles, the other two about 12,000 square miles. Large crops of corn and cotton are raised throughout this area except in the sand hills belt. In the long-leaf pine region there are 17,000 square miles, and here the vast forests of long leaf pine are a great source of wealth to the State. Wherever the timber lands are cleared, they are being put under cultivation. The marls and swamp muck found in this section, when mixed, form a cheap and excellent fertilizer. The pine and palmetto flats around Okefinokee swamp furnish large quantities of long leaf pine, cypress, and saw palmetto, while along the creek-bottom and hummock lands are found these same trees, black-gum, tupelo-gum, titi, and maple. The coast region, about 2,045 square miles, includes the savannas, live-oak lands and islands. The coast lands from the Savannah to the St. Mary's River are noted for magnificent live oaks, also red and water oaks, red cedar, hickory, chinkapin, sassafras, cabbage and blue palmetto. Along the coast lands rice is cultivated, and the Georgia sea-islands produce the larger part of the finest cotton known to commerce. All over middle and southern Georgia grows the sugarcane, richer in saccharine matter than any other known plant from which sugar is extracted.

By reason of its more than 4½° of latitude and different altitudes of its various sections Georgia produces the crops and fruits of every section of the Union, and on its sea islands and extreme southern section of its mainland many of those of the tropics, such as oranges, lemons, bananas, etc. Pomegranates and figs are found all over the State.

The census of 1900 gives the total value of Georgia's agricultural products at $86,345,343. Of this amount $42,534,235 represented the value of the cotton crop, and $17,155,868 that of the corn crop. The sugarcane crop brought $1,690,704; Irish potatoes, $326,853; sweet potatoes, $2,354,390; miscellaneous vegetables, $3,009,306. But in that year both the cotton and corn crops were below normal in Georgia. The value of the peach crop that year was insignificant, because of unfavorable seasons. The normal value of Georgia's corn crop for several years has been in the neighborhood of $19,000,000, and in 1902 her cotton crop brought above $69,000,000, these two crops alone showing a greater value than all her agricultural products combined in the census year. The peach trees in commercial orchards number 16,000,000, of which over half are now in bearing. In a good fruit year the produce of these orchards brings into the State many millions of dollars. In any ordinary year the peach crop of Georgia is worth at least $4,000,000, and in some years it will far exceed those fig-



STATE CAPITOL AT ATLANTA.

ures. Georgia outranks all the States in the number and quality of her watermelons.

Stock raising is very profitable to those who engage in it. In southern Georgia cattle and sheep need very little shelter and for only a few weeks of the winter. The total value of all live stock on farms in 1900, including poultry, was $35,200,507 and the total value of all domestic animals not on farms was estimated at $2,281,059, making in all $37,481,566. The number of specified domestic animals on farms in 1900 was: Dairy cows, 276,024; other neat cattle, 623,467; horses, 127,407; mules and asses, 267,840; sheep (lambs not included), 258,894; swine, 1,424,298. Of poultry there were 4,549,144 chickens, 103,416 turkeys, 208,997 geese, and 64,895 ducks. The total value of all the poultry was $1,458,055. There were 187,919 swarms of bees valued at $242,769.

Geology and Mining.— There are three main geological divisions of Georgia. The Palæozoic in the northwest embraces the counties of Dade, Walker, Catoosa, Whitfield, Chattooga, Floyd, and the greater parts of Murray, Gordon, Bartow, and Polk. Cambrian, Silurian, Devonian, and Carboniferous formations are represented. The rocks are chiefly shales, sandstones, limestone, quartzites and cherts. This is a region of parallel valleys and mountain ridges in which are found valuable deposits of coal, iron, aluminum (or bauxite), manganese, and roofing slate. Hydraulic cement rock is found in large quantities in Bartow County. The crystalline area includes that portion of the State not in the Palæozoic area that runs north of a line extending through Columbus, Macon, Milledgeville, and Augusta. In this area are granites, schists, and gneisses, and in the region which borders both the Palæozoic and crystalline areas are found the marbles for which Georgia is so famous. The marble belt traverses Fannin, Gilmer, Pickens, and Cherokee counties, the most important quarries being in Pickens County. Large quantities of granite and gneiss are found in many localities in the crystalline area.

The gold deposits are found in four belts. The first runs through Rabun, Habersham, White, Lumpkin, Dawson, Forsyth, Cherokee, Cobb, Bartow, Paulding, and Haralson counties. The second belt traverses Rabun, Habersham, Hall, Gwinnett, Forsyth, Milton, De Kalb, and Fulton counties. A third belt traverses Cobb, Paulding, and Carroll counties. A fourth belt goes through Lincoln, Columbia, McDuffie, and Warren counties in the southeast part of the crystalline area. There are some irregular deposits in Towns, Union, Gilmer, Fannin, and Meriwether counties. The iron ores are in the Palæozoic area. The brown iron ores are mined in Bartow, Polk, and Floyd counties. The red iron ores are mined in Walker and Chattooga counties. Ochre occurs in Bartow County, manganese in Bartow and Floyd. The largest bauxite deposits are in Floyd and Bartow counties, but it occurs also in Polk, Walker, and Chattooga counties. Corundum deposits are found in Rabun, Towns, Union, Habersham, Carroll, and Heard counties. Laurel Creek mine in Rabun County near the Carolina line is the largest in Georgia, and one of the most noted in the United States. Pyrite is found in Lumpkin County; copper in Murray and Fannin counties, graphite near Emerson; asbestos in several localities in the crystalline area; talc in Murray, Fannin, and Cherokee; mica in Union and Fannin; barite in Bartow. Of precious stones amethysts are found in Rabun County, a few diamonds in Hall County, some good moonstones in Upson County. Rubies and sapphires of small size have been found in the northeast part of the crystalline area. The coal fields of Georgia are in Dade and Walker counties.

Limestone beds of good quality for both calcimining and building purposes are found in the Palæozoic area and in Hall and Habersham counties in the crystalline area. Limestone for calcimining is also found in different localities in the coastal plain region, which takes in all the southern portion of Georgia. In this region are found marls and phosphates. Through all that part of the State north of the fall line, which runs from Columbus through Macon to Augusta are found clays suitable for the manufacture of common brick and the coarser grades of earthen-ware, while immediately below the fall line in a narrow belt across the State are clays suitable for the manufacture of porcelain, enameled brick, china-ware, terra-cotta, sewer pipes, etc. The annual output of all the mineral products of Georgia is nearly $5,000,000.

Manufactures.— Georgia stands in the front rank of the Southern States in the variety and value of its manufactures and the number of its manufacturing establishments. The total value of all its manufactures by the census of 1900 was $89,789,656. The number of establishments engaged in the manufacture of cotton goods was reported as 68, with 817,345 spindles and 19,398 looms. The capital invested was $24,222,169. But in 1901, after a more searching investigation than ever before in regard to the growth of cotton spinning in the South, the United States Department of Agriculture reported that in 1899 there were 79 mills in operation and that in 1900 the number in operation had increased to 86 with 969,364 spindles. The same report stated that during 1900 there were completed 28 more mills and that the stock had been raised and plans prepared for 13 more. This report agrees very closely with one prepared early in 1901 by the Georgia department of agriculture, which gave a list of the mills by name and showed 111 mills in operation with 1,192,486 spindles and 26,645 looms. In bleached cotton goods Georgia stands fourth in the Union with 24,265,583 square yards. The cotton gins reported in the census of 1900 numbered 4,729 running for four months. Eli Whitney was living in Georgia, when he invented the cotton gin. The cotton oil mills in operation in 1901 numbered 58. They paid above $5,000,000 for cotton seed, which they manufactured into various products, valued at $14,000,000. The fertilizer factories registered with the commissioner of agriculture for the season of 1902 and 1903 numbered 82, many of them being of great capacity and having an immense trade all over the Southern States. In the manufacture of turpentine and rosin Georgia easily leads all the States, exporting in 1900 the vast amount of 14,623,328 gallons of spirits of turpentine and 1,408,928 barrels of turpentine, rosin, and pitch. In 1900 there were 1,254 establishments with a capital of $11,802,716 engaged in the lumber industry. Among the other manufactures the most impor-

tant are printing establishments, flour and grist mills, woolen mills, furniture factories, ornamental iron works, foundries, blast furnaces, carriage factories, car shops, blacksmithing and wheelwrighting, brick, tile and pottery manufactories, marble and stone works, manufactories of paints, chemicals, ice, electric light plants, carpenter work, canning factories, creameries, and numerous others.

Railroads.— The principal railway lines are the Central of Georgia, 1,302.23 miles; Southern, 919.90 miles; Seaboard Air Line, 648.49 miles; Atlantic Coast Line, 667.70 miles; Georgia Railroad, 302.50 miles. There are many other important railroads in the State whose combined mileage is 2,194.50. The total railroad mileage of the State is 6,035.32. Besides these are numerous electric lines in the cities of the State and their suburbs, connecting them in many instances with neighboring towns.

Finances.— In 1903 the assessed valuation of the State was $467,310,646 and the bonded debt $7,531,500 net. The tax rate was $5.30 per $1,000.

Banks.— There are 39 national banks, with a capital stock of $5,046,000, deposits of about $20,000,000, and reserve of about $9,000,000; 243 other banks with about $10,100,000 capital, and over $30,000,000 deposits.

Education.— In addition to her public school system Georgia has numerous private schools and several noted colleges for both sexes. In the public school system there are 7,700 schools, of which 4,919 are for whites and 2,781 for colored. The total number of teachers is 9,180 of whom 5,997 are white and 3,183 colored. The number of normal trained teachers is 2,238, of whom 1,791 are white and 447 colored. The number of pupils admitted during 1901 were 439,645, of whom there were 258,984 whites and 216,359 colored. The average daily attendance was 159,562 white and 105,826 colored, making a total of 265,388. Among the leading higher institutions of learning are: University of Georgia, Athens; and its branches as follows: North Georgia Agricultural College at Dahlonega, Georgia School of Technology at Atlanta, Georgia Normal and Industrial College (for ladies) in Milledgeville, Georgia State Normal School (for both sexes) at Athens, and the Georgia State Industrial College for Colored Youths, near Savannah; affiliated with the University of Georgia, but not receiving State funds: South Georgia Military and Agricultural College at Thomasville, Middle Georgia Military and Agricultural College at Milledgeville, West Georgia Agricultural and Mechanical College at Hamilton. Other noted colleges are: Emory College, Oxford; Mercer University, Macon; Wesleyan Female College, Macon; Shorter Female College, Rome; Agnes Scott Institute, Decatur; Lucy Cobb Institute, Athens; Southern Female College, College Park (near Atlanta); Southern Female College, La Grange; La Grange Female College, La Grange; Andrew Female College, Cuthbert; Monroe Female College, Forsyth; Young Female College, Thomasville; St. Stanislaus College, near Macon; Young L. Harris Institute, Young Harris; Brenau Female College, Gainesville; Piedmont Institute, Rockmart; South Georgia College, McRae. With the exception of the State Industrial College for colored youths, at College near Savannah, all the above-named institutions are for whites exclusively. For the colored people there are the following institutions: Atlanta University, Clark University, Spellman Seminary, Morris Brown College and Gammon University, all at Atlanta; Payne Institute at Augusta, under the auspices of the Methodist Episcopal Church, South.

The number of pupils enrolled in private schools and colleges is 10,097 whites and 4,877 colored, total 14,974.

Religion.— The Baptists have 368,000 members, 3,586 church buildings, and 76,000 Sunday-school pupils; the Methodists have 272,000 members, 3,205 church buildings, and 117,828 Sunday-school pupils; the Presbyterians have 18,000 members, 327 church buildings, and 12,600 Sunday-school pupils; the Congregationalists have 4,714 members, 65 church buildings, and 4,284 Sunday-school pupils; the Episcopalians have 7,976 members, 137 church buildings, and 4,400 Sunday-school pupils; the Disciples of Christ have 9,805 members, 110 church buildings, and 7,147 Sunday-school pupils; the Roman Catholics have 20,000 church members, 40 church buildings, and 2,500 Sunday-school pupils. The Hebrews in Georgia number about 6,200.

Charitable Institutions.— The principal benevolent institutions of Georgia are: the Orphan House at Bethesda, near Savannah, founded in 1739; the State Lunatic Asylum at Milledgeville; Georgia Institute for the Deaf and Dumb, at Cave Spring; Academy for the Blind at Macon; Female Asylum at Savannah; Augusta Orphan Asylum at Augusta; Orphan Home of the North Georgia Conference of the Methodist Episcopal Church South, at Decatur; Orphan Home of the South Georgia Conference of the Methodist Episcopal Church South, at Macon; Mumford Industrial Home for boys and girls, near Macon; Appleton Orphan Home (Episcopal), Macon; Baptist Orphans' Home, Hapeville, near Atlanta; Hebrew Orphan Home, Atlanta; Abram's Home for widows in Savannah.

State Government.— The State Constitution adopted in 1877 carefully guards the rights of the people and prevents extravagant appropriations by the legislature. The governor is elected for two years and receives a salary of $3,000. The state-house officers are: the attorney-general, comptroller-general, adjutant-general, treasurer, secretary of state, state school commissioner, commissioner of agriculture, state geologist, state librarian, commissioner of pensions, three prison commissioners, and three railroad commissioners. The supreme court consists of one chief justice and five associate justices. There are 24 superior court circuits, each having a judge and solicitor. Georgia is represented in the National Congress by two senators and 11 representatives.

Population and Division.— The population of Georgia at each census is as follows: (1790) 82,548; (1800) 162,686; (1810) 252,433; (1820) 340,985; (1830) 576,823; (1840) 691,392; (1850) 906,185; (1860) 1,057,286; (1870) 1,184,109; (1880) 1,542,180; (1890) 1,837,353; (1900) 2,216,331. The total white population in 1900 was 1,181,109 and the total colored 1,034,998. There were also 204 Chinese, 1 Japanese, and 19 Indians. The foreign-born population numbered 7,603 males and 4,800 females. There are 137 counties in the State.

Of 372 incorporated places in Georgia 40

had a population in 1900 of more than 2,000 and 13 of these had a population in excess of 5,000. Atlanta, the capital, had 89,872; Savannah, the chief seaport, had 54,244; Augusta, the greatest cotton manufacturing city of the South, had 39,441; Macon had 23,272; Columbus, the second great cotton manufacturing city of the South, had 17,614. Other cities of the State having over 5,000 inhabitants in 1900 are: Athens, 10,245; Brunswick, 9,081; Americus, 7,674; Rome, 7,291; Griffin, 6,857; Waycross, 5,919; Valdosta, 5,613; Thomasville, 5,322.

History.— A charter for the establishment of the colony of Georgia was obtained from George II., king of England, in June 1732, by a number of benevolent gentlemen of London, whose design was to found a home for the poor of Great Britain and a place of refuge for the Salzburgen and other persecuted sects of the continent of Europe. The colony was also intended as a military settlement to serve as a barrier against encroachments of the Spaniards upon South Carolina. Gen. James Edward Oglethorpe, a man of great liberality and of marked ability and experience in military affairs, being selected by the trustees as governor, brought over 116 emigrants. Landing at Yamacraw Bluff on 12 Feb. 1733, they laid the foundations of the city of Savannah and colony of Georgia. At first rum and slavery were prohibited, but in 1747 these restrictions were removed. During the 10 years of Oglethorpe's administration many settlers of a very desirable kind were brought into the colony, peace with the Indians was secured by treaties, their lands being in every instance procured by purchase, a formidable Spanish invasion was defeated, John and Charles Wesley and George Whitefield preached to the people and Whitefield founded the Orphan Home at Bethesda a few miles from Savannah. In 1752 the trustees of Georgia surrendered their rights to the crown and in 1754 John Reynolds was appointed governor. At the close of the French and Indian war the boundaries of Georgia, which had embraced a territory between the Savannah and the Altamaha rivers, were extended to the Mississippi on the west, and to latitude 31° and the St. Mary's River on the south. Subsequently they were extended on the south to latitude 30° 21′ 39″. Georgia united with the other colonies in resisting the aggressions of the mother country. On 11 May 1775 Col. Joseph Habersham and Commodore Bowen with 30 volunteers seized the powder magazine at Savannah and secured 13,000 pounds of powder, of which the Georgia authorities sent 5,000 pounds to the Continental army at Boston. In March 1776 the Georgians under Col. McIntosh aided by the Carolinians under Col. Bull burned 3 and disabled 6 out of 11 merchant vessels which under the protection of some British war vessels were endeavoring to carry on trade with some loyalist planters. In April 1776 Georgia instructed her delegates in Congress to vote for independence. The signers of the declaration on the part of Georgia were Button Gwinnett, Lyman Hall, and George Walton. In December 1778 the British captured Savannah and early in 1779 Augusta. But the Carolinians under Andrew Pickens and the Georgians under John Dooly and Elijah Clarke by the victory of Kettle Creek recovered Augusta. Subsequently the British defeated Ashe at Brier Creek and repulsed the combined attack of the Americans under Lincoln and the French under D'Estaing at Savannah. This battle at Savannah was one of the most important conflicts of the Revolution. After the fall of Charleston, S. C., in 1780, the British overran all eastern Georgia. But Col. Elijah Clarke made a desperate effort to retake Augusta. Failing he tried again in 1781 and, by the assistance of Pickens and "Light Horse" Harry Lee, succeeded. Almost the last fight of the Revolution was Wayne's victory over the Indian allies of the British near Savannah, 23 June 1782. On 11 July 1782 Savannah was evacuated by the British and the authority of Georgia was established over all her borders. On 2 Jan. 1788 a convention of delegates from the different counties of the State at Augusta ratified the Constitution of the United States on behalf of Georgia.

In 1802 Georgia ceded to the Federal government all her lands west of the Chattahoochee embracing the greater part of the present States of Alabama and Mississippi. In 1807 Milledgeville became the capital. During the second war with Great Britain 1812–15 the Georgians under Gen. John Floyd gained several battles over the Indians and shared with the Tennesseeans in the decisive victories won over the savages by Gen. Andrew Jackson. In the Mexican war Georgia's sons were distinguished, among whom Col. James S. McIntosh was killed at Molino del Rey and W. H. T. Walker was desperately wounded at Chapultepec.

Georgia seceded from the Union 19 Jan. 1861 and furnished to the Confederate army 94 regiments and 36 battalions, embracing every arm of the service. On Georgia soil were fought the battles of Chickamauga, Ringgold, Resaca, New Hope Church, Kennesaw Mountain, Peach Tree Creek, Atlanta, Jonesboro, Allatoona, and numerous smaller engagements and skirmishes. At the close of the Civil War Georgia resumed her career of enterprise in every industrial line, not waiting even for her re-entrance into the Union, which occurred in 1870. During the Spanish-American war Georgia furnished more volunteers in proportion to population than any other State.

Among prominent Georgia citizens have been Gen. Joseph Wheeler, William H. Crawford, John McPherson Berrien, George M. Troup, George R. Gilmer, Herschel V. Johnson, Howell Cobb, Robert Toombs, Alexander H. Stephens, Joseph E. Brown, John B. Gordon, Alfred H. Colquitt, Benjamin H. Hill, Sidney Lanier, the poet; Dr. J. Crawford Long, the discoverer of anæsthesia; Bishop George F. Pierce, Allen D. Candler.

Joseph T. Derry,
Editor of 'Georgia, Historical and Industrial.'

Georgia, South, an island in the South Atlantic, lat. at its north point, 53° 57′ S.; lon. 38° 13′ W. It is 90 miles long, and has high and rocky coasts, inaccessible from ice during a greater part of the year.

Georgia, Strait of, a large inlet of the North Pacific Ocean, between the continent of North America and Vancouver's Island; about 120 miles in length from north to south; the breadth varies greatly in its different parts, from 6 miles to 20. It communicates with the ocean on the north by Queen Charlotte's Sound, and on the south by the Strait of Juan de Fuca.

Georgia, University of, an important university which is at the head of State education in Georgia. It was chartered in 1785 and is the oldest State university. The charter coordinates primary and secondary schools with the university in the scheme of education by the State. The institution was located at Athens, and began academic work in 1801. This is the parent institution and includes four colleges; (1) Franklin College, the college of the liberal arts; (2) State College of Agriculture and the Mechanic Arts, on the Morrill foundation. (3) Law School. (4) Graduate School. The phrase «University of Georgia» in the wider sense includes the various colleges in different parts of the State which are declared by law to be «parts» of the university. These are: North Georgia Agricultural and Mechanical College, at Dahlonega; Medical College, at Augusta; School of Technology, at Atlanta; Georgia Normal and Industrial College, for women, at Milledgeville; State Normal School, for men and women, at Athens; Industrial College, for negroes, at Savannah. The university, in the collective sense, has (1903) 1,884 students of college grade; 156 in professional schools; 585 in preparatory schools; total, 2,527. The members of the faculties number 160. All these institutions are managed for the most part by local boards or commissions, but legal title and control of all of them is vested in the single Board of Trustees of the university. This is a unique feature of organization of the higher education of the State and differentiates it from the system of any other State. Understood in the narrower sense, the single institution at Athens has 359 students, and its income is $50,000 per annum. Among the alumni of national reputation are Howell Cobb, speaker of the House of Representatives and secretary of the treasury; Alexander H. Stephens, John A. Campbell, justice of the United States Supreme Court; senators Robert Toombs, Benjamin H. Hill, Augustus O. Bacon; Joseph and John LeConte, afterward president and professer in the University of California; Henry Timrod, poet; Henry W. Grady and J. L. M. Curry, diplomat and educator. As the university is a State institution, tuition is free for residents of Georgia in all schools except the professional schools; non-residents pay a small fee.

Georgia Bark, a small tree of the Southern States closely resembling the cinchona or Peruvian bark, and belonging to the natural order *Cinchonaceæ*. It has pretty large white flowers, with longitudinal stripes of rose-color, disposed in beautiful clusters at the extremities of the branches; each flower is accompanied with a floral leaf, bordered with rose-color near the upper margin; the corolla is tubular; the stamens five, with a single style; and the capsule contains two cells and numerous seeds. The wood is soft and is therefore unfit to be used in the arts. The inner bark is extremely bitter, and is employed with success in intermittent fevers.

Georgian Architecture, a neo-classic style of architecture that flourished in England from about 1715 to 1800, during the reigns of the four Georges, from whom it derives its name. It was a union of the Italian and Palladian styles divested of excessive ornamentation, and is to be found throughout the United States in buildings of the Colonial period. Among its prominent exponents were Gibbs, Campbell, Chambers, and Dance; Somerset House, and the church of St. Martin's-in-the-Fields, London, are fine types of the style.

Georgian Bay, Canada, formerly LAKE MANITOULIN, the northeastern part of Lake Huron, partly separated from the main body of the lake by the peninsula of Cabot's Head and the island of Great Manitoulin, province of Ontario. It is about 120 miles long and 50 broad.

Georgian, or **Ibernian,** or **Grusinian.** The people (about 600,000) who speak the Georgian language call themselves Karthveli, but are also named Grusini, and inhabit the valley of the upper and middle Kur, those of the Rion and Tchoruk, as far as the promontories of the Ararat chain, and north to the Alazan, beyond which their language is mixed with the tongues of Shirvan and Daghestan, as far as the Caspian Sea. Probably descendants of the Colchi and Albani, they were anciently called Iberi, and, according to tradition, are akin to the Armenians, although their language differs from the Haikanian (*Somasi* in Georgian), and is believed by their learned prince Theimuraz to be primitive. Brosset and Voss (1847) place it among the Indo-European languages. It consists of several dialects, namely: The Karthveli or Georgian proper in the centre, the Kakheti and Imerethi next, then the Mingreli and Guri, and more remotely the Suani and the Lazi, which reaches almost to Trebizond. A colony transported into Asterabad in Persia in 1622 is said to speak a purer idiom than any of those now spoken in Georgia. Georgian literature is mostly founded on that of Greece. The Bible was partly translated in the 8th century, finished in the 18th, and splendidly printed at Moscow, Tiflis, and St. Petersburg. Arabic and European works have also been translated into Georgian. We can mention but a few of the many remarkable national works. Among the romances are the following: 'Tariel' (Of the Man in the Tiger Skin), by Skhotta of Rusthvel, a general of the heroic queen Thamar, with a commentary by King Wakhtang VI. (Tiflis 1793); 'Daredjamiani' (Deeds of Amiran, son of Daredjan, a hero of Bagdad), by the courtier Moses of Khoni; 'Visramiani' (Love of the Princess Vis for Prince Ramin), somewhat resembling Rousseau's 'Héloïse'; 'Miriani' (story of the Chinese Princess Miri), imitated from the Persian. These and many others exhibit lively imagination and good taste. The 'Thamariani' is a panegyrical epic on Queen Thamar, by Tchakhakhadze. In poetry, there are versions of lyrical poems from the Greek, etc., by Georgi Aphoni (11th century); a collection of historic odes; there is also a very keen satirical work by Bessarion Gabas Khoili. There are many histories of Georgia, chronicles, biographies, histories of families, monasteries, etc. The drama began to be cultivated at a late period, especially by Prince Eristov. Wakhtang VI. established a printing office at Tiflis. There are also there at present a national theatre and opera house. The 'Aurora,' a periodical established in 1857, and the 'Kavkas,' a Russian newspaper, are published at Tiflis.

Geotropism, jē-ŏt'rō-pĭzm, the influence which causes a tendency in plants and animals to grow toward the centre of the earth; it is defined by Dr. John Coulter as "sensitiveness to gravity." Geotropism in its simplest form, called "positive," causes growth directly downward, as in the tips of roots, which strike straight down into the earth. So strong is this influence upon roots that they will turn from any abnormal position in which they are placed and bend downward until they reach and penetrate the ground,— an adaptation for the preservation of plants against dislodgment by wind or water. The reverse of this is negative geotropism (apogeotropism), the influence which causes parts of plants, particularly stems, to grow *away from* the earth. A demonstration of these opposing influences in regulating plant-growth is found in the fact that when seedlings are caused to revolve continuously and rapidly for a period, their stems point and increase toward the centre of the centrifugal force, while the roots take the opposite line of growth. A third form of the tendency is called "diageotropism," and leads parts subject to its influence, as runners and rhizomes, to grow horizontally; that is, in a direction at right angles to the plane of positive geotropism. This influence is seen in the tendency of branches and foliage to assume a horizontal position. In all these cases, however, the result is modified and complicated by influences of sunlight, moisture, etc., styled heliotropism, hydrotropism, chemotropism, etc. (qq.v.); and sometimes, as in the case of twining plants, it is impossible at present to extricate them and assign to each its part in the result.

Geotropism, or the influence of gravity, has had a great effect, also, upon the forms of animals, especially in determining proportions and strength of parts with reference to weight. Associated with other influences it determines the "instinct" which leads many of the lower forms of life to seek the earth whenever possible, or at the proper time, a striking example of which is found in those caterpillars which, born in tree-tops, migrate to the ground as soon as born or when ready to begin their metamorphoses.

Gephyrea, jĕf-ĭ-rē'a, worms allied to the chætopod annelids, but differing from them in not being segmented, though provided with bristles. The mouth is either surrounded with a circle of tentacles, or is overhung by a large broad "proboscis," which in the European *Bonellia* may be several times as long as the body and forked at the end. The vent is either terminal or situated dorsally on the anterior end of the body. They possess a true blood system similar to that of annelid worms. The young free-swimming larvæ of certain forms (*Echiurus*) are like the Trochophores (see Larva) of ordinary annelids. The male of *Bonellia* differs remarkably in shape and size from the female, being only 1 millimetre in length, while the female measures 3 inches, with a proboscis from 8 to 12 inches in length. Our most common form is *Phascolosoma*, which is cylindrical, its mouth surrounded with tentacles, the vent opens near the head, it is without bristles, and lives in dead shells, building out the aperture by a conical tube of sand. Its larva is cylindrical, the head small, with a circle of cilia.

Gepidæ, jĕp'ĭ-dē, a people of Gothic origin who settled about the mouth of the Vistula in the 3d century. Before the 5th century they had migrated to the Lower Danube, where they were subjugated by the Huns; but, revolting against Attila's son, they recovered their freedom and established themselves in Dacia. There their power grew so great that they levied tribute from the Byzantine emperors down to Justinian's days. In the end of the 5th century a powerful enemy arose to them in the Ostrogoths; and after them came the Longobards, who, in alliance with the Avars, inflicted a crushing defeat on the Gepidæ in 566. A part of the last named then submitted to the Avars, while a part accompanied the Longobards to Italy. Henceforward they passed out of history.

Gera, gā'rä, Germany, a town in the principality of Reuss-Schleiz, on the right bank of the White Elster, 35 miles from Leipsic. Among the chief buildings are the castle, the old Trinity Church, the town-hall, gymnasia, theatres, library, museum, town-hospital, etc. There are municipal water-works, electric tramways, scientific and artistic societies, etc. Pop. (1901) 45,640.

Gerace, jā-rä'chā, Italy, city in Calabria, on the east slope of the Calabrian Mountains and the shores of the Ionian Sea, 34 miles northeast of Reggio, and 64 miles by rail. It is on the site of the celebrated Greek Colony of Locri Epizephyrii. The cathedral, rebuilt in 1783, is partly of ancient materials. The district produces grapes, oranges, olives, and grain; and coal, iron, and marble are worked in the neighboring mountains. Pop. (1901) 10,595.

Gerah, gē'rä, the smallest piece of Hebrew money, being the 20th part of a shekel, or about 3 cents. Also, in Hebrew weights, a weight corresponding to the coin.

Geraldini, jā-ral-dē'nē, **Allesandro,** the first Roman Catholic Bishop of Santo Domingo: b. in Italy, 1455; d. in Santo Domingo, 1525. He was a soldier, and served in the army of Spain against Portugal, 1475-6, before taking orders. His learning and his friendship with Archbishop Mendoza, of Toledo, procured for him the tutorship of the royal princesses of Castile. He had great influence in the Spanish Court, and is said to have first interested Ferdinand and Isabella in behalf of Columbus. In 1520 he was made Bishop of Santo Domingo, after having held many high places in church and State. His residence and labors in the island, where he spent the remainder of his life, went far toward bringing law and order out of the chaos that followed upon the rule of the Spanish conquerors. His narrative of his journey thither and his description of Santo Domingo, printed in Latin (1631), is of great value and interest. He also wrote a life of Catharine of Aragon in verse.

Gerando, Joseph Marie, zhō-zĕf mä-rē zhā-rōn-dō, Baron de, French author: b. Lyons, France, 29 Feb. 1772; d. Paris, 11 Nov. 1842. He became governor of Catalonia in 1812, and was professor of public law in the law faculty of the University of Paris from 1828 to 1842. His works, treating law, philosophy, and other subjects, include: 'Des signes et

de l'art de penser' (1800); 'Histoire comparée des systèmes de philosophie' (1803); 'Institutes de droit administratif' (1829); and 'Cours normal des institutions judiciaries' (1839).

Geraniaceæ, jē-rā-nĭ-ā'se-ē, the geranium family, consisting of herbaceous plants or shrubs with opposite or alternate leaves, and white, red, yellow, or purple flowers with five sepals and five petals. Sixteen genera and about 750 species are known. They are found in temperate or hot climates, rarely in the arctic regions. They are often astringent and aromatic, abounding in vegetable oil.

Geran'ium, the typical genus of the *Geraniaceæ* (q.v.), having palmately lobed leaves, regular flowers and a five-lobed ovary, terminated by a long thick beak and five stigmas. On coming to maturity the carpels separate from the base and become resolute or spiral. The spotted crane's-bill (*G. maculatum*) is a very familiar species in the eastern and northern States. The root is astringent and has been used medicinally. The tubers of *G. parviflorum* are eaten in Van Diemen's Land, where it is called the native carrot. Indian geranium is the name given by perfumers to a species of *Andropogon*. The so-called geraniums of gardens are mostly species of *Pelargonium*, and are natives of southern Africa. See CRANE'S-BILL; PELARGONIUM.

Gerard, jē-rärd', **Dorothea.** See LONGARD DE LONGGARDE.

Gerard, Emily. See LASZOWSKI-GERARD.

Gérard, Etienne Maurice, ā-tē-ĕn mō-rēs zhā-rär, French marshal: b. Damvillers, Meuse, France, 4 April 1773; d. Paris 17 April 1852. For his brilliant services at Austerlitz (1805) he was appointed general of brigade; he also took a notable part at Jena (1806), Erfurt (1806), and Wagram (1809). During the Russian campaign of 1812 he rendered conspicuous service at the capture of Smolensk in the battle of Valontina-Gora, and at the passage of the Beresina. In 1831 he commanded the French army sent to the assistance of the Belgians against the Dutch, whom he drove out of Flanders, and 27 Dec. 1832 compelled the citadel of Antwerp to capitulate. After the July revolution of 1830 he was appointed marshal and war minister by Louis Philippe; he was again war minister from July to October in 1834.

Gérard, François Pascal, frän-swä päs-kāl, a French portrait and historical painter: b. of French parentage, Rome, Italy, 11 March 1770; d. Paris 11 Jan. 1837. At 10 he was brought to France, and at 16 became the pupil of David. In 1795 he exhibited 'Belisarius,' which first brought him into notice; shortly afterward he painted 'Psyche receiving the First Kiss from Cupid.' His portrait of Madame Bonaparte in 1799 was the beginning of his career as the "painter of kings." Almost all the royal and other celebrities who visited Paris between 1799 and 1837 were painted by Gérard, who owed his success not alone to his skill as a portraitist, but also to the charm of his manners and conversation. His most celebrated portraits are those of Napoleon in his coronation robes, the Queen of Naples and her children, Talleyrand, Talma, Louis Philippe, and Madame Recamier. The grandest of his works are, however, historical pictures, the 'Battle of Austerlitz' (1810) and the 'Entry of Henry IV. into Paris' (1814). Gérard was appointed first court painter and made baron by Louis XVIII.

Gerard de Nerval, zhā'raar'de-ñar'vaal, the pen-name of GERARD LABRUNIE, a French author: b. Paris 21 May 1808; d. there 25 Jan. 1855. His first book to attract attention was a volume of poems, 'Élégies Nationales.' In 1828 he produced his translation of Goethe's 'Faust,' which brought him the author's personal approval, and which Berlioz (q.v.) used largely as the score for his 'La damnation de Faust.' Gerard also wrote several original plays; was a regular contributor to various periodicals; and published 'Les illumines' and 'Contes et facéties' (1852), and 'Scenes de la vie orientale' (1848–50). While insane he committed suicide. His writings were collected in five volumes in 1868.

Gerard Thom (and variously also TUNC, TUM, or TENQUE), Italian monk, founder of the order of the knights hospitallers of St. John of Jerusalem: b. Amalfi about 1040; d. 1120. In the latter part of the 11th century he first visited Jerusalem, and while there was appointed the superior of a hospice for the convenience of pilgrims, and there he organized the religious order afterward so celebrated, duly recognized by a bull of Pascal II. in 1113.

Gerber, gār'ber, **Ernst Ludwig**, a German musical authority: b. Sondershausen, Germany, 29 Sept. 1746; d. there 30 June 1819. He published 'Historische-biographisches Lexicon der Tonkunstler,' a work which, commenced in 1790, was not completed until 1814.

Gerbers. See GUEBERS.

Gerbert. See SILVESTER II.

Gerda, jĕr'dä, (1) In Scandinavian mythology, wife of Freyr, and daughter of the giant Gymer; she is so beautiful that the brightness of her naked arms illuminates both air and sea. (2) In astronomy, an asteriod, the 122d found; discovered by Peters, 31 July 1872.

Gerez, hā-rēs, **Serra de**, Portugal, a mountain chain which ramifies from the mountains of Asturias and stretches between the basins of the Douro and Minho, from north to south, for about 18 miles. It consists generally of a succession of granite peaks, the loftiest of which, Murro de Burageiro, has a height of 4,296 feet.

Gerfalcon, or **Gyrfalcon.** See JERFALCON.

Gerhard, William Paul, American sanitary engineer: b. Hamburg, Germany, 30 July 1854. He was educated in Germany and came to the United States in 1877. He was chief assistant engineer to Col. George E. Waring (q.v.) at Newport, R. I., 1881–3, and has since practised his profession in New York. He is the author of 'House Drainage and Sanitary Plumbing' (1881, 7th ed. 1897); 'Sanitary House Inspection' (1885); 'The Prevention of Fire' (1886); 'Recent Practices in Sanitary Drainage of Buildings' (1890); 'Disposal of Household Waste' (1890); 'Gas Lighting and Gas Fitting' (1894); 'Theatre Fires and Panics: their Causes and Prevention' (1896); 'Sanitary Engineering' (1898); etc.

Gerhardt, Karl, American sculptor: b. Boston, Mass., 7 Jan. 1853. He studied in Paris

only. The Lord's Supper is an evening meal (as originally), preceded by mutual foot-washing (each sex separate), and followed by the right-hand of fellowship and the kiss of peace, and then by communion. Their organization is episcopal, the bishops or elders being elected by the members out of the higher of two grades of ministers, who with the deacons are also elected by the congregations. The latter with the State districts elect delegates (of either sex) to an annual conference, which is the binding legislative and executive authority on a two thirds vote.

The sect had the curious and unique fortune in the early eighties of having one party secede from it, as too progressive, and the other as not progressive enough. The Old Order Brethren objected to its humanitarian, missionary, and Sunday-school activities; the Progressive Brethren to the rules of dress and other conservative decisions of the conference. The Old Order, numbering in 1902 80 congregations, 140 ministers, and about 4,000 members, publish a newspaper, the 'Vindicator,' to oppose education, missions, Sunday-schools, and revivals. The Progressives had 145 congregations, 231 ministers, and 13,000 members, and are increasing at the expense of the "Conservatives," or mother body. They support a college and publishing house at Ashland, Ohio, and issue an organ, the 'Evangelist.' A small body of seventh-day German Baptists, with five churches and some 200 members, is usually included among the Brethren, and its tenets often absurdly accredited to them; but it is a separate church, long since parted from the others.

German Catholics, a religious sect which sprang up in Germany about the close of 1844, which rapidly increased during the four or five following years and then as rapidly declined. The immediate cause of the formation of this sect was the exhibition by Arnoldi, bishop of Trèves, of the holy coat preserved in the cathedral of that city and said to be the coat of Christ. The bishop accompanied the exhibition of the holy coat by a promise of plenary indulgence to whoever should make a pilgrimage to Trèves to honor it. The announcement of this proceeding on the part of the Bishop of Trèves produced a feeling of general astonishment in Germany and drew from a Silesian priest called J. Ronge, who had already been suspended from his charge on account of his independent views, a letter protesting against the exhibition of the holy coat and denouncing the projected pilgrimage as idolatry. This letter was published in the 'Sächsische Vaterlandsblätter' on 16 Oct. 1844, and produced an amount of excitement that was quite unanticipated by the writer. Ronge was excommunicated, but this only increased the general enthusiasm in his favor and when he entered into relations with Czerski, another independent priest who had seceded from the Church, and made along with him an appeal to the lower grades of the clergy to unite in founding a National German Church independent of the Pope and governed by councils and synods, the appeal received a ready answer from a considerable number of those to whom it was addressed. A number of congregations belonging to the new body were formed in the more important towns, especially in Leipsic, under the celebrated Robert Blum, and in Magdeburg under the teacher Kote. In the spring of 1845 there were already about 100. At this time (March 1845) a council was summoned to meet in Leipsic to deliberate on the affairs of the body. Only 20 congregations were represented there, but these nevertheless at once proceeded under the presidency of Prof. Wigard to arrange a system of doctrine and practice which was to form the basis of union for the whole Church. The Bible was recognized as the sole standard of faith, and its interpretation was left to reason, "penetrated and animated" by the Christian idea. Only two sacraments were admitted, baptism and the Lord's Supper. In matters of ritual each congregation was left free to carry into practice its own views. The organization of the new Church was almost the same as that of the Presbyterian dissenting churches of Scotland. Each congregation was to choose its own pastor and elders. Affairs of a general interest were intrusted to the management of a general council to meet every five years, but the decisions of this council were to be ratified by a majority of the congregations before they became valid. The confession of sins, the hierarchy of the clergy, and the celibacy of the priests were abolished and the authority of the Pope was not recognized. On the subject of purgatory nothing was declared either for or against it. The constitution of the new Church was thus a Protestant one, but in some respects the German Catholics went even further than the majority of Protestants in a liberal direction, inasmuch as they claimed for all, complete religious liberty and declared their religion to be capable of development and modification with the progress of the human mind.

The Church established on this basis had at first, as has already been stated, great success. The most eminent men of the liberal party regarded the movement with sympathy, or at least with interest. Gervinus expressed his belief that great benefits might result from it. Many Protestants, dissatisfied with the subjection of their religion to state supervision, joined the body, which, at the end of 1845, counted 298 congregations. But it was not long before the spirit of opposition began to show itself. The majority of the governments in Germany at the instigation both of the Protestant and the Roman Catholic clergy began to use repressive measures against the new body. Prussia contented itself with regulating the exercise of their worship; but some of the other states went farther. At Baden the adherents of the sect were deprived of their political rights. Austria took the course of banishing them from her dominions. But persecution from without did less hurt than the divisions within the body. Almost immediately after the meeting of the council at Leipsic a congregation had been formed at Berlin which refused to abide by its decisions. Czerski and Ronge, the two originators of the sect, became the leaders of two opposing parties within it, one of which, that headed by Czerski, clung to the traditions and doctrines of the Roman Catholic Church, rejecting only the supremacy of the Pope and the union between Church and State; while the other sought for more freedom, converted religion into a sort of popular philosophy and began to mix up with it questions of politics, exhibiting strong democratic tendencies. These were most plainly manifested during the revolutionary epoch of 1848. The schism be-

tween the two parties was then complete. One section of the congregations of German Catholics professed to have only religious ends in view, while another section openly pronounced itself in favor of socialistic principles.

From the year 1850, however, there were several attempts to re-establish the unity of the body. An effort was made to reintroduce harmony by widening the basis of union. Instead of founding a religion, a council held at Gotha in June 1859, proposed the formation of a religious association or confederation into which all free Protestant and even Jewish congregations were to be admitted. Legislation in the different states had become more tolerant and the carrying out of the scheme of the council of Gotha seemed to be at least practicable. But the result proved otherwise. The association consisted of too heterogeneous elements. While some of the members receding further and further from orthodoxy proclaimed simple deism as their religion and abolished baptism and the Lord's Supper, others on the contrary lost themselves in an exaggerated mysticism. According to the most recent statistics there are still about 100 congregations of German Catholics in Germany; but their numbers only amounted to about 6,200 in 1895.

German East Africa, the largest German colonial possession, extending from lat. 1° to about 11° 41′ S., and from lon. 29° to 40° 40′ E. It has a coast line of 620 miles, and lies between British East Africa, Indian Ocean, Portuguese East Africa, Rhodesia, Congo Free State, and the British Sudan. The area is 384,000 square miles. The German empire is represented by an imperial governor, who appoints a council of five in each of nine communes. There is a military force of 232 Germans and 2,000 natives. The region produces almost every kind of tropical fruit, fibres, sugar, tea, etc. In 1901 over 1,600 tons of copra were exported. The chief seaports are: Dar-es-Salaam (pop. 13,000); Bagamoyo (pop. 14,000); Saadani, Pangani, Kilwa (pop. 10,000 each), and several smaller towns. A railroad from Tauga is open for traffic to Muhesa and Korogme, 54 miles. There are nine telegraph stations in the coast towns. The trade is chiefly with Zanzibar and Germany. Pop. (1901) 6,750,000 natives, 15,347 foreigners, mostly Arabs, Syrians, and Loanese.

German Empire. See GERMANY.

German Evangelical Protestant Church, in the United States, a religious body, liberal in doctrinal belief, having no confession of faith. Its ministers are associated in district unions. There are 52 churches having a membership of 36,156.

German Evangelical Synod of North America, a religious body, accepting the symbolical books of the Lutheran and Reformed churches, representing in the United States the State Church of Prussia, which is a union of the Lutheran and Reformed bodies. It celebrated, 12 Oct. 1890, the semi-centennial anniversary of its organization in the United States. In 1900 there were 909 ministers, 1,129 churches, and 203,574 members.

German Ivy, (*Gynosys cordifolia* or *Senecio scandens*), a creeping plant of the *Compositæ* family, with fleshy light-green leaves. It is commonly grown as a house plant.

German Language and Literature. The German language, called by the Germans *Deutsch* or *Die deutsche Sprache*, is one of a group or family of allied tongues known by the name of Teutonic or Germanic, and including English (Anglo-Saxon), Dutch, Danish, Icelandic, Swedish, and Gothic; to which may be added, as of less importance, and having more the character of dialects, Norwegian, Frisian, Plattdeutsch (the vernacular of the North German lowlands), and Flemish, which differs little from Dutch. It is also distinguished as High German, being originally the language of the more inland and elevated parts of Germany. Three chief periods are usually distinguished in the history of the language — those of the Old, the Middle, and the New High German — the last being the ordinary literary German of the present time. Old German is known by monuments of the 7th century, when it was split up into three divisions: Upper German among the Alemanni, Bavarians, and Longobards; Low German among the Frisians, Saxons, and Westphalians; and a middle group in Hesse, Thuringia, and Franconia. The eastern part of Germany was at that time occupied by Slavic tribes. The Franconian dialect prevailed during the reign of Charlemagne and for some time after; the Longobardic early fell into disuse.

Middle High German became literary in the 12th century, its poetry giving it a predominance over a wide area. It was surpassed during the following year by the Suabian, which had a still wider field. Other idioms attempted to rival these two, but in all the writings of the 14th and 15th centuries the Suabian influence is apparent. The Low German 'Sachsenspiegel,' and other law books, were translated into Upper Saxon, which at last became the language of literature and cultivated society in Germany, in consequence of the translation of the Bible by Luther. Luther's translation may be said to have settled the High German as a literary language upon a fixed and permanent basis. The language was afterward much corrupted by admixtures from foreign languages, especially during the Thirty Years' war, which deluged Germany with hosts of mercenaries from all parts of Europe; but the great writers of the 18th and 19th centuries — poets, historians, philosophers, critics, etc.— have brought it to its present eminence. Although wanting the precision and clearness of the French, the soft music of the Italian, and the flexibility and grammatical simplicity of the English, yet it has acquired a majesty, energy, and charm of its own, and the German translators of Homer, Dante, and Shakespeare have reproduced the thoughts of the original with a force and fidelity unrivaled in any other language.

Literature in Germany received its first impulse from the fondness of the Germanic races for celebrating the deeds of their gods and heroes. Of these early songs in praise of the gods Tuisco and Mann, and of the hero Arminius, who conquered the Romans in the great battle in the Teutoburger Forest, nothing even in a translated form has been handed down to us. The legends immediately connected with the Gothic, Frankish, and Burgundian warriors of the period of national migration — the 'Dietrich' (Theodoric) and 'Siegfried-Sagen,' the 'Hildebrandslied,' etc.— have for the most part some historical foundation, and many of them

were eventually incorporated in the 'Nibelungenlied,' the most celebrated production of German mediæval poetry. On the introduction of Christianity literary activity really began. The British missionaries established cloisters and brotherhoods in Germany between the 6th and 8th centuries, and laid the foundation for that system of education, which was most fully developed under the fostering care of Charlemagne. Metrical translations of the Evangelists appeared in the 9th century in the High and Low German dialects; the 'Krist' of the High German in rhyme, the 'Heliand' in the other idiom, preserving the ancient alliterative form of verse. One of the best specimens of Old High German literature is a translation of the Psalms by Notker about the same period. The 'Ludwigslied,' a pæan in honor of the victory of Louis III., king of the Franks, over the Normans in 883, which Herder extols as one of the best specimens of early German poetry, was composed in Old High German by a Frankish ecclesiastic. The preservation of the 'Hildebrandslied' is also due to churchmen, who transmitted it partly in the high and partly in the low forms of the dialect. Several Latin hymns, too, were based on Hunnish and Burgundian legends and the 'Thiersagen,' beast-fables; but with these exceptions the clergy were generally opposed to the national poetry, on account of its pagan associations.

In the 12th and 13th centuries poetry passed from the monasteries and ecclesiastical schools to the palaces of princes and the castles of nobles. The deeds and tales of the Crusaders, the fresh bloom of chivalry, the lays of the troubadours and the trouvères of Provence and Normandy, had a powerful influence on the spirit, form, and language of German poetry. Many of the poets of this period were nobles by birth, some of them even princes. Heinrich von Veldeke was the first to introduce into his heroic poem 'Eneit' (composed, it is said, after a French translation of Virgil) that spirit of devotion to women called by the old Germans *Minne* ("Love," hence the name *Minnesänger*, "Love-Minstrel"). Veldeke is considered the originator of the heroic minstrel songs, but he is far surpassed by Wolfram von Eschenbach, the author of 'Parzival,' and the unfinished epics 'Titurel' and 'Wilhelm von Oranse.' In the first-mentioned poem are embodied the legends of King Arthur, the Knights of the Round Table, and the San Graal (Holy Grail). These traditions, together with the exploits of Charlemagne, of Alexander the Great, and the Trojan heroes, inspired also the lays of Gottfried of Strasburg, Herbort von Fritzlar, Hartman von der Aue, and Konrad of Würzburg. The love songs of this period breathe a purer and more reverential devotion to woman than the songs of the French troubadours. A species of lay, called *Wachtlied*, "watch-song," peculiar to this time, consists of a dialogue between a lover and the sentinel who guards his mistress. The inventor, or at least the most gifted author in this department of lyric poetry, is Walter von der Vogelweide, the victor in the poetic war of the Wartburg. Next to him rank Heinrich von Ofterdingen, Reimer der Alte, Heinrich von Morungen, Gottfried von Nerfen, and the Austrian bards Nithard and Tannhäuser. Several hundreds of these poets were engaged in traveling from palace to palace, and from castle to castle. Their songs were mostly in the Suabian dialect, and the poets constituted what is called the Suabian school, which may be said to have risen and fallen with the Suabian emperors of the house of Hohenstaufen (1138–1254). The crowning event of this era was the appearance of the 'Nibelungenlied' (about 1210), the greatest of the Old German epics. The origin of this poem is a subject of as much controversy as that of the 'Iliad' and 'Odyssey.' Some will have it that the poem is but a series of popular ballads strung clumsily together, without the slightest alteration, by some obscure personage; others will have it that the first part, Siegfried's Tod, was the production of one author, and the second part, Kriemhilden's Rache, that of another; while again a third authority asserts it to be the work of one hand. It was closely followed by a not unworthy successor, Gudrun, and by the 'Helden-Buch' (Book of Heroes), which consists of a collection of fragmentary pieces treating of the same legends as the Nibelungenlied, but mixed up with tales of the Crusaders. In the 13th century didactic poetry began to be cultivated with some success: the dawn of historical literature is heralded by several local chroniclers. Ulrich von Lichtenstein deplores, in his poem 'Frauendienst' (1275), the decline of chivalry, but his attempt to revive its spirit was hopeless. In the troublous times of the Interregnum (1256–73) the gay and gallant knights degenerated into little else than gloomy robber chiefs; and poetry passed from their abodes to the homes of the private citizen and the workshops of the shoemaker and weaver. These plebeian songsters formed themselves into guilds in the imperial cities — Nuremberg, Frankfort, Strasburg, Mainz, etc., and were called *Meistersänger*, in contradistinction to the knightly *Minnesänger*. In the 14th century Germany produced several mystical theologians, disciples of Meister Eckhart, the most celebrated of whom were Tauler and Suso, whose sermons and writings paved the way, in some measure, for the Reformation. The last echoes of the chivalric lays were two allegorical romances, 'Theuerdank' (in verse) and 'Weisskunig' (in prose), written in great part, if not wholly, by the Emperor Maximilian I., and transcribed and perhaps polished by his private secretary, Melchior Pfinzing. An important event of the 14th century was the foundation of the University of Prague (1348), soon after followed by similar establishments throughout the length and breadth of the empire. The only good poetry in the 14th, and up to the close of the 15th century, were the spirited lays of Halb Suter and Veit Weber, who celebrated the victories of Switzerland over Austria and Burgundy. Classical culture was greatly furthered by the establishment of Deventer University in 1400 by Gerhard Groot, and of many schools in imitation of it in Germany and the Low Countries. Among the students were Hegius, Reuchlin, and Agricola. Peurbach was the first restorer of mathematical science, and his pupil Regiomontanus (Johann Müller) was the greatest mathematician of the 15th century. The invention of printing caused a still increasing literary activity, and the works printed in Germany between 1470 and 1500 amounted to sev-

eral thousand editions. In 1498 there was published the celebrated beast-epic 'Reineke Vos' ("Reynard the Fox"), which, according to Jakob Grimm, originated with the Frankish tribes, who carried it with them when they crossed the Rhine and founded an empire in Gaul, and from whom it was diffused among the neighboring tribes of northern France and Flanders. The 16th century opens with the foundation of the University of Wittenberg (1502), and, along with the Reformation, inaugurates a new era in literature by Luther's translation of the Bible. The Misnian dialect as used by him is so pure, harmonious, and beautiful that all the other dialects, which had until then alternately predominated in German composition, were from this time gradually banished from literature, and the idiom of the Bible (now known as the Neu Hochdeutsch, New High German) has now become the sole medium of intercourse in cultivated society in the empire. Besides his translation of the Scriptures, Luther (1483–1546) enriched the national literature with many religious songs, many of which have become classical, and have found hosts of imitators, the most successful of whom were Decius and Speratus, and in the 17th century Gerhard. Michael Weiss translated the hymns of Huss into German. The writings of Luther, Zwingli (1484–1531), Sebastian Frank (1500–45), Melanchthon (1497–1560), Ulrich Von Hutten (1488–1523), a remarkable anonymous treatise, 'Das Büchlein von der Theologie,' edited by Luther himself, and other works by eminent reformers and scholars, constitute the principal theologic literature of the Reformation. History was now written in a superior style, and with greater comprehensiveness, by Frank in the 'Zeitbuch' and 'Weltbuch,' and by Sebastian Münster (1489–1552) in his 'Kosmographie'; also by Tschudi (1505–72) in 'Chronicles of Switzerland,' and by Aventinus (1477?–1534), the Bavarian chronicler. Seb. Frank published also a collection of German proverbs, which was, however, far inferior to that published under the title of 'Auslegung deutscher Sprüchwörter,' by his predecessor, Johann Agricola (1492–1566). The principal literary events in prose belles-lettres of this period is the appearance of a popular literature in the shape of 'Volksbücher' (People's-books), in which were reproduced, in short compass, many of the ancient traditions, legends, and tales of Germany and other lands. Boccaccio, Poggio, and other Italian novelists, were also introduced by translation to the notice of German readers. The Reformation period was particularly fruitful in satirical and allegorical works. One of the most remarkable of the former kind was the 'Narrenschiff' (Ship of Fools), by Sebastian Brandt or Brant (1458–1520), a metrical satire on the follies of the century, and which was imitated by Thomas Mürner (1476–1536) in his 'Narrenbeschwörung' (Conjuration of Fools). Mürner was one of Luther's bitterest opponents, and wrote a coarse yet clever satire on him, 'Von dem grossen Lutherischen Narren' (Of the great Lutheran Fool). The most talented and satirical didactic poet of the period was Johann Fischart (1545?–89), author of a romantic poem, 'Das glückhafte Schiff,' which is regarded as a model, and numerous other works, many of them written in the Rabelaisian style. The story of 'Faust,' of the 'Wandering Jew,' the 'Autobiography of Götz von Berlichingen' (afterward celebrated by Goethe), and the comical 'Till Eulenspiegel,' which relates the freaks and drolleries, fortunes and misfortunes, of a wandering mechanic, were among the most popular works of this age. At this time appeared Hans Sachs (1494–1576), the cobbler of Nuremberg, the Meister of the Meistersänger, as he is called by Herder, who excelled in all styles of composition, in tragedy, comedy, psalms, allegories, fables, tales of a religious and of a broadly comic character, etc. Frauenlob and Michael Behaim also wrote several notable poems; and Rosenblüt and Folz were tolerably successful playwrights, the former being also one of the best tale-writers of his time. The most successful rival of Sachs as a dramatist was his townsman, Jakob Ayrer (died 1605), who excelled him in the skilful arrangement of plot. Among the purely didactic fabulists were Burkard Waldis, Erasmus Alberus, and Georg Rollenhagen, the two former being also famous as composers of hymns. During the excitement occasioned by the Reformation almost all branches of literature were cultivated, but it was in learned and scientific treatises that the age was most prolific. Besides Melanchthon, whose influence secured the preponderance of the Aristotelian philosophy in the Protestant schools of Germany, there were Luther, Camerarius, Cornelius Agrippa, Paracelsus, Copernicus (astronomy), Leonhard Fuchs (botany and medicine), Conrad Gesner (zoology and classics), and Agricola (mineralogy). At the close of the 16th century few of the great scholars were left, and classic learning was beginning to decline in the early part of the 17th. The universities and schools which had sprung up under the influence of the Reformation were no longer animated with the zeal of the reformers, but engrossed by subtle polemical and scholastic strifes. The 17th century has been called, in German literature, the period of imitation. Most of the poets of this age were graduates of universities; and learned societies on the model of the Academia della Crusca were formed for the purpose of improving the language and literature. After their dissolution they were replaced by literary and scientific associations in Leipsic, Berlin, Hamburg, Halle, Königsberg, and in several other of those Protestant towns in north Germany which, greatly owing to the establishment of their universities, had become the chief centres of culture. A new school of poetry was founded, of which Martin Opitz (1597–1639) was the leader. His works are more remarkable for smoothness of versification and an occasional felicity of expression than for true poetic inspiration; but they exerted a healthy influence at a time when the Thirty Years' War and the growing taste for inferior French and Italian compositions threatened to annihilate all vestiges of pure German poetry, and when the reforms introduced by Luther into the language still required to be insisted upon. This first Silesian school, as it was called, after the birthplace of its chief, counted among its members many ingenious writers, as Simon Dach (1605–69), Von Zesen (1619–89), Johann Rist (1607–67), and, greatest of all, Paul Fleming (1609–40), whose lyrics are natural and cheerful as the songs of a lark. Equally great, but totally different in disposition, was the leader of the second Silesian school, Andreas

Gryphius (1616–64), who, besides being the author of many passionate yet melancholy poems, may be looked upon as the founder of the modern German drama. In poetry and in the drama Gryphius had several imitators, the principal being Lohenstein (1635–83), whose tragedies teem with slaughter and pompous phrases; Christian Weise (1642–1708), a comedian of infinite humor, though sometimes of a rough sort; and Hoffmann von Hoffmannswaldau (1618–89), Asman von Abschatz, Christian Gryphius, and others. Both the Silesian schools were opposed first by the "court poets," Canitz (1654–99), Neukirch (1655–1729), Günther (1695–1723), and others; and, secondly, by the Hamburg school, best represented by Brockes (1680–1747) and Wernike (died about 1720). Among the satirists and epigrammatists Laurenberg (1591–1659), Rachel (1617–69), and Logau (1604–55) particularly distinguished themselves. The most successful novelists were Bucholz, Von Zesen, Shupp, Anton Ulrich, Duke of Brunswick, Scriver, Butschky, but more especially Moscherosch (1601–69), the author of the 'Wunderliche und wahrhafte Geschichte Philanders von Sittewald'; and Grimmelshausen (1625–76), whose 'Simplicissimus' is the most entertaining book of the century. In both the last-mentioned works are to be found interesting and vivid pictures of German life and manners during the Thirty Years' War. Among the scientific and philosophic writers of the period we may mention Kepler (1571–1631), the astronomer (who wrote in Latin); Puffendorf (1632–94), the publicist; Spener (1635–1705), the founder of the German pietists; and Reimarus (1694–1765). In philosophy and learning Latin had been hitherto the general medium of literature, and Jakob Böhme (1575–1624), the great mystic, stood almost alone in using the vernacular in communicating philosophical instruction. In the latter part of the century, however, appeared Christian Thomasius (1655–1728), an able jurist, pietistic philosopher, and writer, who established the first German learned periodical (Leipsic, 1688–90), and who first substituted his mother-tongue for the barbarous Latin of the schools in his philosophical lectures at Leipsic and Halle. Leibnitz (1646–1716) was the first to lay a scientific basis for the study of philosophy, but his works were composed chiefly in French and Latin. Wolff (1679–1754), his disciple, shaped the views of his master into a comprehensive system, and published his works in the German language.

Under the impulse of the new philosophical ideas Germany became, in the 18th century, excited on the subject of reform in literature, as it had been in the 16th on that of theology. The century opened with the foundation of the Berlin Academy by Leibnitz (1700). Gottsched (1700–66) labored in the same direction at Leipsic as Thomasius, exerting himself to make the German language the only medium of higher instruction, and publishing in it manuals of philosophy and science. His correct and formal taste led him to advocate the classical rules of composition of Racine and Corneille, and in religious and philosophical matters he in some measure sympathized with Voltaire. These leanings brought him into violent opposition with Bodmer (1698–1793) and Breitinger (1701–76), who admired the English poets as much as Gottsched did the French, and who were strictly orthodox in matters of religion. They carried on a paper war in their respective journals, until at length many who had rallied round Gottsched became disgusted with his pedantry and conceit, and separating themselves from him, established a periodical afterward well known in German literature, the 'Bremer Beiträge,' in which they opposed their former idol. At the same time they formed a poetical union, to which Hagedorn was friendly, although he never became a member, but which was eventually joined by Klopstock. Among the contributors to this journal were Rabener (1712–91), a popular satirist with a correct and easy style; Zachariä (1726–77), a serio-comic epic poet; Gellert (1715–69), the author of numerous popular hymns, fables, and a few dramas now forgotten; Kästner (1719–1800), a witty epigrammatist and talented mathematician; Giseke, Cramer, Fuchs, Ebert, and many others of more or less note. The journal was printed at Bremen, but the poets resided for some time at Leipsic, whence they adopted the name of the "Second School," while the followers of Bodmer styled themselves the "Swiss School." Related to the latter was the school of Halle, to which belonged Lange, Pyra, Uz, Götz, etc. The most distinguished poets of this school were Kleist (1715–59), who took Thomson, the author of the 'Seasons,' as a model, and Ramler (1725–98), the author of some fine odes; Gleim (1719–1803), a celebrated fabulist, at first a follower of Bodmer, gathered a nucleus of writers about him, and for about 40 years exercised considerable influence on German literature; but his fame was diminished by the criticism of Herder. Gessner of Zürich (1730–87) gained in his time a high reputation as a writer of idyls; but Herder thinks he has been much overrated. The poets of most influence and importance of the period, however, are Hagedorn (1708–54), whose fables and lyrics have rendered him immortal among his countrymen; Albert von Haller (1708–77), the eminent physiologist, who was remarkable as a writer of descriptive poetry; and greatest of all, Friedrich Gottlieb Klopstock (1724–1803), the author of the 'Messias,' the mystic and devout faith of which deeply impressed the world, while as a work of art it was thought to rival the epics of Milton and Dante. Strikingly opposed in style and spirit to this poem is the graceful Græco-Parisian epic, 'Oberon,' by Christoph Martin Wieland (1738–1813). But it was reserved for Gotthold Ephraim Lessing (1729–81) to give a new direction to German literature. He did for it what Luther had done for the language. He established a new school of criticism and dealt the fatal blow at French influence when Frederick the Great was courting the Gallic muse. Lessing's tragedy, 'Emilia Galotti,' his comedy of 'Minna von Barnhelm,' and his philosophic drama, 'Nathan der Weise,' are models of dramatic composition. He exerted a powerful influence on the drama by unfolding for the first time all the beauty, vigor, and originality of Shakespeare before the German mind, and by the profound and philosophical criticisms in his 'Dramaturgie.' He condemns all foreign models except the ancient classics and Shakespeare, and desires literature to reflect its own stirring energies in the drama as being the most perfect form, and not in the continental mediæval epic, which the spirit of the age shrinks from. Among the many literary labors with

which his name is associated, the most celebrated was a periodical, 'Literaturbriefe,' which he founded in 1759 in Berlin in conjunction with Nicolai, the publisher and author. The principal contributor after himself was his friend Moses Mendelssohn (1729–86), one of the noblest characters in the history of German literature. Both Klopstock and Wieland were criticised in that periodical, and it was the first to discover the merit of the unfortunate Winckelmann, the classic archæologist, and the philosophical genius of Kant, although at that time he had written but a few short treatises. Shortly after the commencement of this publication a new influence was brought to bear upon the literary world by Herder (1744–1803). His mind was a complete storehouse of universal knowledge; he had studied closely the poets of all nations, become intimately acquainted with the Hebrew, Greek, and Latin writers, and above all possessed a cosmopolitan humanitarian spirit, which, together with his poetical genius, manifested itself most suggestively in the crowning work of his life, the 'Ideen zur Philosophie der Geschichte der Menschheit.' He contributed in no small degree to the study of Oriental poetry, and was the first to direct attention to the beauty of the early popular songs of all nations, and particularly of his own. The earnestness and dignity of his character exercised a powerful influence upon the great poets of his time, and he succeeded in imbuing other minds with his poetical conceptions, both by his personal intercourse with them, and by his varied contributions to literature. The writings of Winckelmann (1717–68), in which are given the results of his studies of the remains of ancient art, modified all the old conventional theories of the beautiful, and by his exertions, combined with those of Lessing, whose 'Laokoon' was elicited by Winckelmann's suggestions, the spirit of art and poetry was brought back to the genuine and simple taste of the Greeks. The students of Göttingen University (then the most brilliant in Germany) became, through the teaching of Heyne, the accomplished critic and commentator, deeply impressed with the new ideas, and under the influence of the reforms which were then initiated in all departments of thought and life, founded in 1770 the 'Musenalmanach,' a literary journal, and not long afterward a poetical union known as the Göttinger Dichterbund or Hainbund. Among the members of the union were Gottfried Aug. Bürger (1748–94), author of 'Lenore' and other wild and picturesque ballads and songs; Voss (1751–1826), the translator of Homer, and author of one of the finest German idyls, 'Luise,' together with the two brothers Stolberg, Boie, Hölty, Claudius, Hahn, Cramer, Johann Martin Miller, etc. The Reformatory period was followed by a time of transition and excitement known in Germany as the "Sturm-und-Drang Periode," which found its fullest expression in the 'Leiden des jungen Werther' (Sorrows of Werther), one of the earliest works of Germany's greatest literary genius Johann Wolfgang von Goethe (1749–1832), and with more exaggeration and less poetic inspiration in the sensational tragedies and novels of Klinger (1753–1831), from one of whose dramas the period was so designated; and in the works of Schubart, Heinse, Lenz, and Müller. The literary excitement was driven to the highest pitch of excitement by the 'Räuber' of Friedrich von Schiller (1759–1805), afterward the friend and worthy coadjutor of Goethe. By the joint exertions of these two great men German literature was brought to that classical perfection which, from a purely local, has since given it a universal influence. Goethe possessed the plastic imagination of a Greek, the glowing fancy of an Oriental, and the melodic ear of an Italian, together with genuine German feelings. Versed in almost every human science, master in every department of literature, he became the acknowledged sovereign of intellectual Germany; while Schiller, by his enthusiastic and eloquent pleading for political and intellectual freedom, his wide human sympathy, and by the simple yet classical elegance of his style, became the favorite of the people. The contemporaries and immediate successors of Lessing, Herder, and Mendelssohn in the walks of science and philosophy and history are A. G. Baumgarten (1714–62), the founder of the science of Æsthetics, whose works are written in Latin; Meir, the popular interpreter of his ideas; Lavater (1741–1801), the physiognomist; Lichtenberg (1752–99), his keen and polished antagonist; the historians Mosheim (1694–1755), Dohm, Möser, Spittler, Johannes Müller; Adelung, the philologist; Basedow and Pestalozzi, the educationalists; Ernesti, Spalding, Rosenmüller and Michaelis, theologians; Eichhorn, in theology and universal and literary history; and the scientific writers Blumenbach, Euler, Vega, Herschel, and others. Closely related to the theological and psychological writers stand Nicolai, whose novel Sebaldus Nothanker satirized unsparingly the dead, hard dogmatism, or violent fanaticism of the narrow-minded and illiberal teachers of theology; Engel, the author of Lorenz Stark; Jacobi, the author of several metaphysical novels; Jung Stilling, the tailor, in whose autobiography Goethe took such a deep interest; and Jean Paul Friedrich Richter (1763–1825), who, possessing a deep fund of humor and pathos, and a wide experience of life, wanted in a painful degree the power of arranging his ideas, and often of lucidly expressing them in consequence. In the field of pure metaphysics Immanuel Kant was succeeded by Fichte (1762–1814), Hegel (1770–1831), and Schelling (1775–1854).

Partly produced by the influences of the "Sturm-und-Drang" period, and partly trained in the laws of art laid down and worked out by Goethe and Schiller, the so-called romantic school gradually succeeded in gaining public attention about this epoch and holding favor for a considerable time. The head of this school, Von Hardenberg, better known under the pseudonym of "NOVALIS" (1772–1801), was a poet and prose writer remarkable for scattered thoughts of wisdom and deep poetic insight, combined with morbid sentiment, and buried under a crude style. Diametrically opposed to him, although considered as belonging to the same school, is August Wilhelm von Schlegel (1767–1845), the author of the antique tragedy 'Ion,' and of many elegies and romances, but chiefly remarkable for his admirable metrical translation of Shakespeare, his critical and æsthetic writings on the drama, and his labors connected with the Indian and Sanskrit literature and language. The specialty of his equally eminent brother Friedrich von Schlegel (1772–1829) was the history of ancient and modern literature, and the

philosophy of history. The most original representative of the school was Ludwig Tieck (1773–1853), whose poetical dramatization and collection of fairy and popular tales reflect the romance of mediæval poetry with beauty and vigor, but with a mystic feeling akin to superstition. La Motte Fouqué is unrivaled in the power of giving Ariel-like delineations of the mysteries of fairy lore, instinct with grace, loveliness, and spirituality; as, for instance, in his 'Undine.' Chamisso (1781–1838), a sweet lyrical poet, and the author of 'Peter Schlemihl'; Tiedge (1752–1841), the author of 'Urania'; and Werner, a mystic religious poet, all belong to this school; and with the exception of the spirited poet Seume (1763–1810), and the Aristophanic Platen (1796–1835), most of the writers had a morbid passion for romantic and sentimental views of life. This epoch comprises the lyric poets Stägemann, Kosegarten, Baggesen, Matthisson, Salis, Mahlmann, and Eichendorf, many of whom belong to the romantic school. Among the novelists and tale writers are Achim von Arnim (1784–1831), and Clemens Brentano (1777–1842), the compilers of a collection of popular songs, 'Des Knaben Wunderhorn'; Ernest Hoffman (1776–1822), the author of the fantastic and wild tales 'Elixire des Teufels,' 'Kater Murr,' etc., which carry to a climax the supernaturalistic element of the romantic school; Musæus, the author of a collection of 'Volks-Märchen,' or popular fairy tales; Thümmel, Knigge, and Karl Immermann (1795–1840), the author of the famous novel 'Münchhausen.' Among female authors about this period, the most notable are Bettina von Arnim, Goethe's celebrated correspondent, and in the early part of her career associated with the romantic school; the Countess Ida von Hahn-Hahn, Auguste von Paalzow, Amalie Schoppe, Fanny Lewald, Johanna Schopenhauer, Frederike Brun, and others.

The war of liberation against Napoleon I. introduced a strong manly enthusiasm for a time into the hitherto gloomy and melancholy productions of the romanticists. The spirit of national liberty was roused and sustained by the stirring patriotic lays of Ernst Moritz Arndt (1769–1860); Theodor Körner (1791–1813), the gallant soldier poet, whose last song, the 'Schwertgesang,' had just left his hand when he had to grasp the sword for the heroic encounter with the hated French, in which he died, as he wished, a hero's death; Friedrich Rückert (1789–1866), the author of the 'Geharnischte Sonnette,' also celebrated for his versions of Oriental poetry and imitations of troubadour songs; Ludwig Uhland (1787–1862), whose ballads and metrical romances brought him a world-wide fame, and who was the recognized head of the modern Suabian school. This poetical union had its headquarters in Stuttgart, the seat of the great publishing firm of the Cottas, and the residence of the eminent critic Wolfgang Menzel. It counts among its members Gustav Schwab (1792–1850), Justinus Kerner (1786–1861), Gustav Pfizer, Eduard Mörike, Karl Mayer, etc. The efforts of Lessing, Herder, Klopstock, and others to revive the popularity of early German poetry, and to destroy the then prevailing taste for French and Italian literary forms, have contributed to give a powerful impulse to the researches into the ancient German literature, which was to some extent fostered by Jahn's spirited work on 'Deutches Volksthum.' The brothers Grimm — Jakob (1785–1863), Wilhelm (1786–1859), were the more immediate founders of this new branch of philological and poetic investigation. Among the many eminent names in general philology are those of Bopp, Pott, Schleicher, Steinthal, and Karl Brugmann.

The political excitement produced in Germany by the French July revolution (1830) gave a new direction to literary activity. A school of writers styled "Junges Deutschland," arose, in whose poems, dramas, and novels the social and political ideas of the time were strongly reflected. The forerunners of this party were Ludwig Börne (1786–1837), by his pungent political satires, and Heinrich Heine (1799–1856), a writer gifted with great penetration and political and philosophical insight. No writer except Goethe has been better able to introduce into lyrical poetry that language which seems to be the echo of the longing thoughts of the human heart, but he wilfully destroyed his own influence by his frivolity, sensualism, and irreligion. The most important member of the young German school was Karl Gutzkow (1811–78), author of several celebrated novels, 'Der Ritter vom Geist,' 'Der Zauberer von Rom,' etc., a popular dramatist, and one of the most active journalists of Germany. Among other notable representatives of the school are Mundt (1807–61), Kühne, Laube, and Wienbarg. Another eminent writer of this period is Baron Sternberg, whose novels reflect the social and political condition of his country; and closely related to him in tendency and aim stands Prince Pückler-Muskau. The taste for poems and novels of a social and political character has been gratified by Hoffmann von Fallersleben (1798–1874), Georg Herwegh, Dingelstedt, Kinkel, Prutz, Freiligrath, etc. Among other poets of the most recent period are Emmanuel Geibel, Grabbe, Gottschall, Paul Heyse, Wolfgang Müller, Bodenstedt, Anastasius Grün (Count Auersperg), Lenau, Otto Roquette, Karl Beck, Meissner, Redwitz, Kinkel, Zedlitz, Hamerling, Bishop Pyrker, Ambrosius, Baumbach, Becker, Bleibtrein, Holz, the brothers Hart, Redwitz, and Wolff. The most successful novelists of this or the immediately preceding generation are Karoline Pichler (1769–1843), Zschokke (1771–1848), Karl Spindler, W. Häring (1797–1871), the German Sir Walter Scott (famous under his pseudonym "WILIBALD ALEXIS"; Berthold Auerbach (1812–1882), the author of the 'Village Tales of the Black Forest'; Gustav Freytag, best known as the author of 'Soll und Haben' (known to English readers as 'Debit and Credit'); and the 'Verlorene Handschrift'; Gerstäcker, Wil. Hackländer, L. Schüking, Heyse, G. zu Putlitz, Mügge, O. Müller, Klaus Groth, Anzengruber, Elizabeth Bürstenbinder (Victor Werner), Dahn, Ebers, Eugenie John (E. Marlitt), Jensen, Keller, Kirschner, Kretzner, Lindau, Marie von Ebner-Eschenbach, Mailiff, Mauthner, Meyer, Ring, Rosegger, Baroness von Suttner, Storm, Sudermann, Spielhagen and Wilbrandt. Dramatic literature has fallen from the high estate which it reached through Lessing, Goethe, and Schiller. Their more immediate successors were Gerstenberg (1737–1823), Cronegk, Lesewitz, C. F. Weisse; Iffland (1759–1814), Werner (1768–1823), the founder of the 'Schicksalstragödie' (Fate Tragedy), by his piece called the 'Vierundzwan-

zigster Februar'; Kotzebue (1761–1819), one of the most prolific dramatic writers of all nations, having written in his short span of life about 200 pieces in all, some of which have been put upon the English stage; Karl Immerman (1796–1840); Raupach (1784–1852); Franz Grillparzer, Bauernfeld, Gutzkow, Benedix, Charlotte Birchpfeifer, Münch-Bellinghausen (better known as Fried. Halm), Laube, Hebbel, Gottschall, G. Freytag, Heyse, Greif, Ganghofer L'Arronge, Lindau, Moser, Hauptmann, Suderman, Wilbrandt, and Wildenbruch.

The tendency of the most eminent German minds has shown itself more and more in their partiality for the spheres of science and learning, rather than the poetic and dramatic department of literature. Alexander von Humboldt (1769–1859) gave a great impulse to almost all branches of knowledge by his 'Cosmos,' his 'Travels,' and his 'Views of Nature,' and by the general suggestiveness of his labors. While he marks a new epoch in the pursuit of the natural sciences, another great movement was initiated in historical researches by Niebuhr (1776–1831), the historian of Rome. Heeren (1760–1842) investigated history in connection with political and commercial relations. Other noted historians are Ranke, the historian of the popes; Dahlmann, Rotteck, Schlosser, Gervinus, the author of a 'History of German Literature,' and the historian of the 19th century; Lappenberg, author of a 'History of England,' completed by Pauli, which is considered a valuable work by English authorities themselves, Mommsen ('History of Rome,' etc.), Sybel ('French Revolution'), etc. Among the historians of literature are Von Hammer-Purgstall, an earnest student of Oriental literature, and author of histories of Turkish and Arabian literature; Julian Schmidt, who has written a history of German literature since the death of Lessing; and Heinrich Kurz and W. Wackernagel, historians of German literature, the work of the latter unfortunately uncompleted at his death in 1869. Another worker in the field of historical literature was King John of Saxony (1801–73), who, under the name of "PHILALETHES," published a metrical translation of Dante, enriched with many valuable notes and commentaries; and Eckermann, the compiler of the 'Conversations of Goethe,' while biography has been well represented by Varnhagen von Ense (1785–1858), Pertz, David F. Strauss, and others. The literature of travels — especially travels undertaken with scientific objects in view — was greatly stimulated, as already stated, by A. von Humboldt. Other names of note in this department of literature are Ida Pfeifer (1798–1858), the brothers Schomburgk, Lepsius, Brugsch, the brothers Schlagintweit, Barth, Vogel, Rohlfs, Schweinfurth, etc. We conclude with a list of eminent men in the principal departments of learning in Germany. In the natural sciences: Oken, Burmeister, Carus, Bern. Cotta, Ule, Endlicher, Bischoff, Kopp, Poggendorf, Wackenroder, L. von Buch, Naumann, Liebig, Erdmann, Helmholtz, Virchow, Schleiden, Grisebach, Vogt, Bessel, Brehm, Haeckel, Bastian, Sachs, etc. In medicine: Johannes Müller, Burdach, Ehrenberg, Hecker, Blasius, etc. In astronomy and mathematics: Bessel, Encke, Struve, Gauss, Mädler, etc. In geography, ethnology, and statistics: Karl Ritter, Wappäus, Petermann, Scherzer, Berghaus, Klöden, Stein, Streit, etc. In theology and biblical criticism: Baur, Bleek, Ewald, Strauss, Keim, Ritschl, Pfleiderer, Harnack, and others. Among historians of art there are Kugler, Burckhardt, Lübke, and others. In philosophy: Schopenhauer, Feuerbach, Rosenkranz, Kuno Fischer, von Hartmann, Lotze, etc. Consult: Histories of German literature by Bartels, Kurz, Wackernagel, Vilmar, Julian Schmidt, Koberstein, Gervinus (German poetry), Goedeke, etc.; and in English, Metcalfe's, Menzel's, Scherer's, Francke, Gostwick and Harrison's, Mac Callum, Wells, etc.

German Measles. This disease is acute, very contagious, and of unknown causation. It differs from measles in the mildness of its onset and symptoms, in the quicker appearance of the rash after the first signs of illness, and the more rose-red tint of the developed rash. It is distinguished from scarlet fever by its mildness of onset, the patchy character of the rash, without diffuse redness, and the shorter duration. The disease develops in 10 or 12 days after exposure, lasts about 3 to 5 days, and is followed by a moderate branny desquamation. Complicating bronchitis, pneumonia, gastro-intestinal catarrhs, and kidney disturbance may occur, but are infrequent.

German Ocean. See NORTH SEA.

German Silver, a white alloy for tableware, consisting of nickel, copper and zinc in various proportions. The best quality consists of four parts copper, two parts nickel, and two parts zinc, but this quality is the most difficult to work. For some purposes the proportion of copper is slightly increased, and for articles which are to be cast instead of stamped or hammered about 2 per cent of lead is added. To make a good malleable alloy, the three metals of which it is composed should all be of the best quality. It is harder and tougher than brass, and takes a fine polish. In color it is sufficiently near silver to make it valuable for plating with that metal. This, together with its hardness in resisting wear, has caused a great demand for German silver for certain wares made in Birmingham and Sheffield.

Spoons and forks of this alloy are made in immense numbers. Such articles as salvers, dish-covers, jugs, teapots and the like are also largely made of it, but these objects, or at least some of them, are still more largely made of a greatly inferior alloy, because much softer. German silver has a coppery odor and is readily attacked by acid liquids, such as vinegar, which coat it with verdigris. Spoons and forks made of this alloy should therefore either be plated with silver or carefully kept clean. Of late years, through care in preparing a suitable alloy, large objects, such as the bodies of jugs and coffee-pots, can be formed of sheet German silver by "spinning" it on the lathe, instead of by stamping or by the slow process of hammering. Formerly it was only a soft alloy that could be so treated. For some time past there has been a tendency to substitute for electroplate — that is, German silver plated with real silver — white alloys having nickel for their basis. These, however, are but varieties of German silver known under different names, such as silveroid, argentoid, navoline, and nickeline. Some of them contain small quantities of tin, cadmium, and other metals. Mountings for ship-cabins,

bar-fittings, forks and spoons, and other similar articles have been manufactured on a considerable scale from these new alloys. See ELECTROPLATE; METALS.

German Southwest Africa, a German protectorate in West Africa, coast extending from Cape Frio to Walfisch Bay, inland to lon. 20° E.; area, estimated, 322,450 square miles. Coast infertile and desolate; inland are richer tracts. Damaraland is the name of the north district, Namaqualand and Luderitzland lying to the south. Damaraland is occupied by the Southwest African Company, an Anglo-German syndicate, which was formed in London in 1892, and obtained from Berlin a concession to search for and work the minerals of the district, including the copper mines of Otavi, but outside of the district worked and occupied by the German Southwestern Africa Colonial Company, which district consists chiefly of the coast lands. The German government, owing to complaints that too great favor had been shown to the Anglo-German Company, decided to give preference to German settlers, and to reserve certain parts of the country for them for 10 years. The country is apparently rich in copper and in agricultural resources, though undeveloped. The seat of administration is at Great Windhoek, 170 miles inland from Walfisch Bay. The German government decided in 1897 to commence the building of a railway from the coast to the interior. Pop. (1900) 221,000.

Germander, jėr-man'dėr (*Teucrium*), a large and widely distributed genus of labiate herbs, of which all the European species are of old medicinal repute on account of their aromatic bitter and stomachic properties. The species are numerous. The wall germander or true germander (*T. chamædrys*), often found on ruined walls, has probably been introduced from Europe. Wood germander or wood sage (*T. scorodonia*) is a very common British plant, in dry bushy or rocky places. It is very bitter and slightly aromatic. It is used in the Island of Jersey as a substitute for hops. Water germander (*T. scordium*), in wet meadows, has a smell like garlic. Cat or sea thyme (*T. marum*), of southern Europe, like catmint and valerian root, has great attractiveness for cats. It is still sometimes used in the preparation of sneezing powders. The American species (*T. canadense*) is also known as wood sage.

German'ia, a country of ancient Europe. See GERMANY.

German'icus Cæsar, Roman general: b. 15 B.C.; d. Epidaphnæ, near Antioch, 9 Oct. 19 A.D. He was the son of Nero Claudius Drusus, and of Antonia, daughter of Mark Antony and niece of Augustus. By desire of Augustus he was adopted in the year 4 A.D. by Tiberius, whom he accompanied in the war against the Pannonians, Dalmatians, and Germans. In the year 12 he was consul, and next year was appointed to the command of the eight legions on the Rhine. He was at Lugdunum Batavorum when news came of the death of the Emperor Augustus and of the mutiny for more pay and shorter service among the soldiers in Germany and Illyricum. Germanicus hastened to the camp and quelled the tumult by his personal popularity; and at once led his soldiers against the enemy. Crossing the Rhine below Wesel, he attacked and routed the Marsi, and next year marched to meet the redoubtable Arminius (q.v.), the conqueror of Varus and his legionaries, whose bones had lain unburied for six years in the Teutoburg Forest. With solemn rites his soldiers buried these sad relics of disaster, then advanced against the foe, who, retiring into a difficult country, managed to save himself, and was not subdued till the year after, when Germanicus again carried a part of his army up the Ems in ships, crossed to the Weser, and completely overthrew Arminius in two desperate battles. Tiberius, jealous of the glory and popularity of Germanicus, recalled him from Germany in the year 17, and sent him to settle affairs in the East, at the same time appointing as viceroy of Syria, in order secretly to counteract him, the haughty and envious Cn. Calpurnius Piso. Germanicus died, probably by poison. His wife, Agrippina, and two of her sons were put to death by order of Tiberius; the third son, Caligula, was spared. Of the three daughters who survived their father, Agrippina was as noted for vice as her mother for virtue.

Germanium, jėr-ma'nĭ-ŭm, a metallic chemical element discovered in 1886 by Dr. Winkler in a silver ore (argyrodite); symbol, Ge; atomic weight, 72.3. It has a melting-point about 1,650° F. (900° C.); is oxidized when heated in air; crystallizes in octahedra; has a perfectly metallic lustre, and is of a grayish-white color. As gallium had been named from France, the new metal was named after Germany. Fifteen years before its discovery its existence was prophesied by Mendeleëff as required to fill the gap in the periodic table between silicon and tin.

Germans in the United States, The. The German immigration hither may be roughly divided into two sections, as a whole or more than formal difference in their effect on us and themselves, though of course divided by no exact line; before the Revolution and after it. The colonial immigration created settlements in great part purely or dominantly German, and still retaining frequently German names and deeply German characteristics; and in one remarkable case, that in eastern Pennsylvania, a great agricultural district in many things tenaciously German still. The later migration has mostly coalesced with our own people, though in some cities so great as to give them unmistakably German characteristics.

Colonial.— The first German immigrations were predominately religious, like the English to New England; by far the greater part were sectaries from the Rhine country, the home of Mysticism and Pietism. So many were from the Palatinate that all German immigrants were called «Palatines» in America. Persecution was the usual cause; sometimes, as with the Dunkers (see GERMAN BAPTIST BRETHREN), rather a desire, supplemented by material hardships, for a settlement devoted purely to their own faith. The poverty and misery left by the Thirty Years' War, but slowly changed under a series of extremely bad rulers, also drove great numbers to emigrate. The immediate stimulus was William Penn's visit to Germany in 1677; he saw the conditions there, and on receiving his grant of Pennsylvania in 1681, wrote to Benjamin Furly recommending it as an asylum for oppressed sects. Literature about Pennsylvania and the Quakers soon abounded, and Furly founded two

emigration companies, one at Crefeld on the Rhine and one at Frankfort-on-the-Main. The first emigrants were Mennonites (q.v.), from Crefeld, led by Francis Daniel Pastorius (q.v.), probably about 40 in all; they sailed in the Concord, their Mayflower, and landing at Philadelphia 6 Oct. 1683, settled at the later Germantown (q.v.), incorporated 1691, but dissolved soon after because no one would hold office. These were they who, in 1688, signed the first anti-slavery petition in America. The settlement of Labadists (q.v.) at Bohemia Manor in Maryland, was mainly Dutch, but contained some Germans. In 1694 the millennial society afterward nicknamed the "Woman in the Wilderness," a mixture of Rosicrucianism, Mysticism, Pietism, etc., settled as hermits on the Wissahickon, but scattered on the death of their leader, Kelpius. From 1705 to 1710 a body of German Reformed settled German Valley, Morris County, N. J.; and coming in large numbers later, they spread from the Delaware to Hackensack, centring at German Valley and New Germantown. On the last day of 1708, 61 Lutherans from Landau, ruined by the devastations of the War of the Spanish Succession, settled Neuburg (Newburg), N. Y., but failed and scattered. The same cause, however, added to the terrible cold winter of 1708–9, which destroyed the vines and fruit-trees, led to a tremendous exodus to England, some 15,000 in all flocking over and living in camps, in dreadful misery and destitution, and many dying. Some thousands were colonized in Ireland, other thousands of Catholics who refused to become Protestants were deported back to Germany, 4,000 or 5,000 ultimately came to America. One colony, under Baron de Graffenried, were settled in North Carolina at the confluence of the Neuse and Trent, naming the place New Berne (Newbern); many were massacred by the Tuscaroras, and part removed to Virginia, where Spotswood settled them at Germanna. The largest single body, however, was settled on both sides of the Hudson at West Camp (Saugerties) and East Camp; the latter was broken up, part founded Rhinebeck, and others took lands from the Mohawks, and founded Schoharie. The government would not recognize the title to the latter, and repeatedly granted the lands over their heads. At last, worn out, part of them migrated to the Mohawk Valley, where their growth and the stream of German emigrants that followed made it "for 30 miles a German river"; Herkimer, German Flats, Mannheim, Oppenheim, Minden, Palatine Bridge, etc., livingly commemorate them. But the greater portion removed to Pennsylvania in 1723 and settled at Tulpehocken Creek, the western outpost of the present Berks County; the eastern part had been settled by another band five years previous, and the district rapidly filled up between into a German stronghold, for some reason mainly Lutherans. Meantime the original Mennonites had spread over the present Montgomery County; and in 1709 eight families had taken lands on Pequæ Creek, now in Lancaster County, some 60 miles from Philadelphia. Renewed persecutions of the Mennonites by the Swiss drove them first to Holland, then in 1717 to their brethren in Pennsylvania, settling on Pequæ; in 1726 another large body came over — the last two by aid of a "Committee of Foreign Needs" in Rotterdam, which in 1732 declined to extend further aid. These made Lancaster a German district. In 1719 and 1729 the Dunkers removed bodily from Germany, but seem to have settled among others rather than founded new places. It was among them at Pequæ that Conrad Beissel first sojourned, before founding his convent of Ephrata, which seems to have been confounded with Dunker practices. In 1733 the Schwenkfelder, followers of Caspar Schwenkfeld, after undergoing frightful persecutions in Silesia from the Emperor Charles IV. to make them turn Catholics, came to Pennsylvania and settled along the Perkiomen in Montgomery County. The Germans now formed the deep and populous frontier of Pennsylvania. The earliest settlement of Lebanon and Dauphin counties was begun at Quitapahilla or "Snakes' Hole"; about 1720 a Jewish colony was planted near Schaefferstown. Across the Susquehanna, the first white settlement of York and Adams counties was founded in 1730 by Germans at Conewago. In 1732 the German swarms crossed the border: a band entered the valley of Virginia, and within a generation the Germans were all through the valley, and had founded three towns — Strasburg, Mecklenburg (renamed Shepherdstown from its founder, Schaeffer, translated Shepherd), and Woodstock. Others settled near Frederick, Md., and in 1735 an organized band came thither under John Thomas Schley, who built the first house in Frederick (laid out 1745). In 1739 Jonathan Hagar came to his tract of "Hagar's Choice," and in 1769 founded Elizabethtown, renamed by the people Hagerstown. By this time the Germans had filled western Maryland between South Mountain and the Conococheague, founding several towns, including Graceham of the Moravians. The trading road between the Maryland German settlements and the valley of Virginia was the chief emigrant road. The first German settlement in South Carolina was in 1731, at Purysburg on the Savannah, the work of a promoter with purely business ideas; but it was too malarious, and did not prosper. In 1735 a large emigration fixed on Orangeburg district (named later from the Prince of Orange); other bands followed rapidly, and in a few years some 20 colonies had established themselves there — Amelia, Saxe-Gotha (now Lexington), Fredericksburg, etc. By 1775 they had spread over all western South Carolina. About 1750 a colony settled at "Dutch Forks" (Saluda and Broad, Newberry County); the latest one was at "Hard Labor Creek," Abbeville County, the speculation of a rascally officer who left his colonists to starve in England, but they were rescued and forwarded by benevolent Englishmen. The first Georgian settlement was in 1734. It was of Lutherans from Salzburg in Austria, persecuted by the Roman Catholic archbishop; and with Oglethorpe they selected a site 25 miles up the Savannah, which they called Ebenezer. The next year others came; and in 1736 the "Great Embarkation" of Salzburgers, Moravians, and German soldiers for Fort Frederica on St. Simon's Island, to be an outpost against the Spaniards. The latter soon disappeared; the former settlement was infertile, unhealthy, and ill-placed for trade; and a new location was found which proved satisfactory. By 1741 there were about 1,200 Germans, Swiss, and Palatines in Georgia. In 1752 a large band of Würtembergers came

to the district and founded St. Matthæus's parish. There were many Germans in Charleston and Savannah; and isolated settlements in the Carolinas besides those mentioned; and a great southern movement of the Pennsylvania Germans was proceeding along the Maryland and valley of Virginia trail, filling the mountain counties of North Carolina with German settlers. That province thus had a strip of English colonization on the coast, then one of German, then a third of Scotch-Irish, then a fourth of Germans again. Meantime the Georgia Moravians had left there on being required to fight the Spaniards, and coming to Pennsylvania, were given by George Whitefield a tract near the "Forks of the Delaware" (Easton), which they named Nazareth; quarreled with their leader as to a "limited atonement"; Whitefield turned them out in midwinter, and they secured another site, which they called Bethlehem. Zinzendorf came thither in 1741. (For their Indian mission work, see their name; for the tragedy of the Delaware towns, see GNADENHÜTTEN.) After the close of the French and Indian war, the Germans speedily filled up western Pennsylvania, first opened to white settlement by the Albany Treaty of 1754, but kept closed by the war. Some of these counties are still full of German names, as Berlin, Pfautz Valley, etc. Two minor items may be mentioned, in earlier chronological order. In 1719 John Law, as part of his Mississippi Bubble, sent a colony of Germans to Louisiana, where they settled in the present Arkansas; but on Law's collapse they grew frightened and went to New Orleans to take ship for home again. The French government, however, would not let them go, and resettled them at Côte d'Allemande (Germans' Shore). In New England two feeble attempts were made at Waldobore, Me. (from Gen. Waldo, descendant of a Von Waldow), and Braintree, Mass. (at New Germantown). Both were unprosperous; the latter joined the former, which finally broke up, and the settlers went to North Carolina.

Later.— Of the overflow from the Atlantic States which began to populate the new West as soon as it was opened to settlement — the first wave after the Revolution, the second after the War of 1812 and the surrender of the frontier posts — the Germans were a considerable portion as being already in mass on the frontiers; so that the first tier of Western States had a heavy German strain before the new foreign emigration began in some force about 1820, when the Bureau of Immigration was established. But for the first decade the volume was small, only 6,761; and in the early thirties it continued slender. Then it rose greatly under the bad industrial conditions and political repression of the people, and amounted to 152,454 in 1821–30; thence on in mighty volume, the figures are, for the German empire alone, 1841–50, 434,626; 1851–60, 951,667; 1861–70, 787,468; 1871–80, 718,182; 1881–90, 1,452,970; 1891–1900, 543,922. No definite reason is assignable for the enormous leap in the last decade but one, followed by a decrease nearly back to the figures of half a century before. Since 1900, about 100,000 more have come over. Besides these, German Austria has sent us about 500,000. In all, besides the immense German element already existent in the population, some 5,700,000 have been added to it straight from the old country since 1820. In 1900, of the German-born population in the United States (2,943,239 from Germany and German Austria), about 33 per cent were in the North Atlantic States, and 55 in the Central West. New York State came first, with 558,517; then Illinois, with 350,381; Wisconsin, with 250,096; Ohio, with 215,735; Pennsylvania, with 279,945; New Jersey, Iowa, Minnesota, and Missouri having well over 100,000 apiece. Of the cities, New York had 393,770, or over one ninth of its population; Chicago 182,553, or nearly one ninth; Philadelphia, 76,473; St. Louis, 61,-344, nearly one ninth; Milwaukee, 55,470, or nearly one fifth — by far the heaviest percentage of any city in the United States; Cleveland, 45,278, or toward one eighth; Cincinnati, 38,873, or between an eighth and a ninth — its great German stock belonging mostly to the last generation; Buffalo, 37,496, or between a ninth and a tenth; San Francisco, 37,035, or nearly one ninth; Baltimore, 34,564; Detroit, 32,498, or a little over one ninth. The tenacity of this percentage is most curious.

Ger'mantown, Pa., a former village, since 1854 the 22d ward of Philadelphia. Considerable historical interest is attached to the place. It was settled by the Germans, under a grant from William Penn, in 1684, and on 4 Oct. 1777 a battle took place between the armies under Washington and the English under Howe. See GERMANTOWN, BATTLE OF.

Germantown, Battle of, 4 Oct. 1777. Howe having captured Philadelphia, stationed his army across the Germantown road north of the city and east of the Schuylkill; the left wing with its supports on the river, the right "in the air" to the east. He shortly detached part of it to reduce the forts which blocked the Delaware below the city; and Washington planned the capture of the weakened army, starting after dark on the evening of 3 October. His right under Sullivan and accompanied by himself, with six brigades, was to move down the main street and crush the British left; the Pennsylvania militia to march along the river and take it in flank; the left under Greene was to divide, three brigades under himself taking the British right in front and flank, while two others were to move to the east and come up in its rear. This would drive it back upon the left and both on the river, and it was hoped would compel surrender. A mile or so north of the British centre on Mount Airy, were a battalion of light infantry and a battery; in a field just left was a regiment under Col. Musgrave; a little south on the main road was the massive stone house of former Chief Justice Chew. At sunrise a heavy fog came up and left all darker than ever. The British advance bodies were overwhelmed by the Americans, and the battery captured; but Musgrave took shelter in Chew's house, and after an unsuccessful attempt at breaching it with the light guns, the Americans left a brigade to besiege it and pushed on. Despite this delay and the warning to the British, both their wings soon began to give way before the American onset. But in the fog, the heavy firing at Chew's house drew Gen. Stephen with his brigade, on Greene's right, too far west, thinking the main fight was there; and Wayne on Sullivan's left had turned considerably east and came in front of Stephen, who took him for

the enemy and attacked him in the rear. Wayne's men were driven against the next left of Sullivan's remaining brigades, a panic started, and a general retreat began. The British took the offensive, and reinforced by Cornwallis from Philadelphia, pressed the Americans hard; but the latter soon regained composure and retired in good order, though one regiment of Greene's was surrounded and captured. The Americans, however, brought away several captured cannon, and all their own and their wounded. Their loss in killed and wounded was 673, the British 535. Stephen was accused of having drunk too much on the night march, court-martialed, and dismissed from the army. Despite the failure of the plan, the ultimate results were very great. The audacity of the Americans in attacking the British so soon after the defeat of the Brandywine, and the fighting qualities displayed, were a large factor in determining the French alliance.

Germany (Latin, *Germania;* German, *Deutschland;* French, *Allemagne;* Spanish, *Allemania*), the name given to a large part of Central Europe, and in one sense including all the countries in which the mass of the people are German in race and language. Parts of Switzerland, Austria, and Russia may thus be said to be German. The name, however, in its usual and more restricted application, is confined to those states which constitute the German Empire. Taken in this sense, Germany from east to west is about 750 miles long, and from north to south 600 miles. It is bounded on the north by the Baltic, Denmark and the North Sea, the Baltic coast measuring 830 miles, the North Sea coast 300 miles, and the northern land boundary of Schleswig 53 miles; on the west it is bounded for 512 miles by Luxembourg, Belgium, and Holland; on the southwest and south by Austria and Switzerland for 1,170 miles, also on the southwest by France for 275 miles, and on the east by Russia for 725 miles. The table in the next column shows the political divisions which constitute the German Empire, with their respective areas and population.

The small island of Helgoland, now forming part of Prussia, was added to the empire in 1890. As each state is described under its own name, the description here is confined to leading features which belong to Germany as a whole.

Topography.— The physical features are greatly diversified and present an irregular succession of mountains and valleys, table-lands and plains, making it extremely difficult to arrange them for the purpose of a distinct general description. The whole country may, however, be considered as consisting of a mountain region in the south with a great north plain between it and the sea. This mountain region does not in average height exceed 5,000 feet and is extremely complicated, consisting of a great number of separate ranges, which ramify in all directions and become so interlaced with each other that the limits assigned to them are in many instances arbitrary. The only range which has any title to be considered as a common centre is the Fichtelgebirge, continued east by the Erzgebirge and the Riesengebirge, southeast by the Böhmerwald, west by the Thüringerwald, Rhöngebirge, and Spessart, and carried to its northern limit in the Harz. The western boundary of this region is formed chiefly by the Schwarzwald and Odenwald. Across the Rhine are the Vosges Mountains on the French frontier. The great plain in the north extends without interruption to the German Ocean and the Baltic and flattens down so much when it approaches them as in many places to require artificial protection from their waves. Its length west to east may be about 550 miles, and its average breadth 200 miles.

Political Divisions	Area in sq. m.	Pop. Dec. 1, 1900
Kingdoms		
1. Prussia	134,603	34,472,509
2. Saxony	5,787	4,202,216
3. Bavaria	29,282	6,176,057
4. Würtemberg	7,528	2,169,480
Imperial Territory		
5. Alsace-Lorraine	5,600	1,719,470
Grand Duchies		
6. Baden	5,821	1,867,944
7. Hesse	2,965	1,119,893
8. Mecklenburg-Schwerin	5,135	607,770
9. Mecklenburg-Strelitz	1,131	102,602
10. Oldenburg	2,479	399,180
11. Saxe-Weimar	1,388	362,873
Duchies		
12. Brunswick	1,424	464,333
13. Saxe-Meiningen	953	250,731
14. Saxe-Coburg and Gotha	755	229,550
15. Saxe-Altenburg	511	194,914
16. Anhalt	906	316,085
Principalities		
17. Waldeck	433	57,918
18. Lippe	469	138,952
19. Schaumburg-Lippe	131	43,132
20. Schwarzburg-Rudolstadt	363	93,059
21. Schwarzburg-Sondershausen	333	80,898
22. Reuss (elder line)	122	68,396
23. Reuss (younger line)	319	139,210
Free Towns		
24. Bremen	99	224,882
25. Hamburg	158	768,349
26. Lübeck	115	96,775
	208,830	56,367,178

Hydrography.— The central mountain region and plateau forms part of the great watershed of Europe and either gives rise to more than one of its most important rivers or sends them their principal affluents. Thus the Danube, rising near its extremity, flows across it in an easterly direction, and does not quit it till it about reaches the extreme east of Bavaria. The Rhine, in like manner, though it neither rises nor terminates within Germany, flows within it for the greater part of its course and is considered by the Germans as their national river par excellence. After these come the Elbe, strictly speaking the greatest river of Germany, inasmuch as almost its whole basin lies within it; the Oder, Weser, Main, Neckar, Mosel, Ems, and Eider — all of which are navigable. The principal lakes are the Lake of Constance or the Bodensee, 1,306 feet above sea-level, between Würtemberg and Switzerland, and the Amersee, the Wurmsee, or Starnberg Lake, and the Chiemsee in Bavaria.

Geology.— The central highland consists principally of Cretaceous, Jurassic, and Triassic formations. The northern plain, to all appearance, was once covered by the sea, alluvial deposits of great depth being spread over almost every part of its surface, but generally with so large a proportion of sand as to make it for the most part naturally unfertile. Considerable Devonian and Silurian areas extend over the middle

Rhine region while Quaternary formations occur on the north and Tertiary on the south. South of the Weser highland is a great central area composed chiefly of Triassic rocks, while on the west is a Cretaceous zone. The Vosges Mountains west of the Rhine valley, and the Black Forest on the east comprise large areas of crystalline rocks. Dyassic and coal formations are found in the Oldenburg and in the Ruhr regions.

Mineral Resources.— Germany possesses varied mineral riches, the most important of which are common coal and brown coal, iron, zinc, lead, and salt. In respect of its mineral wealth the Prussian monarchy takes a prominent place among the states of Europe, especially in the production of zinc. After Prussia the kingdom of Saxony is the most important mining country in Germany. Gold and silver are obtained in the Harz Mountains and in the kingdom of Saxony; gold to a limited extent also in Bavaria. Iron is chiefly obtained in Prussia, Alsace-Lorraine, Bavaria, Brunswick, and Saxony. Copper, lead, and zinc are found chiefly in Prussia. Tin is found only in the kingdom of Saxony; quicksilver, antimony, and sulphur are mainly confined to Prussia; nickel and alum are obtained chiefly in the same state; arsenic chiefly in Saxony, graphite in Bavaria, and blue and green vitriol in Prussia and Saxony. The most extensive coal beds lie in the kingdoms of Prussia and Saxony. Brown coal is obtained also in the duchy of Anhalt. Rock salt is obtained in considerable quantities in Prussia, Anhalt, and Würtemberg. Marble, alabaster, kaolin, calamine, molybdenum, cinnabar, lime, asbestos, slates, millstones, freestones, trass, and sundry precious stones — as amethysts, garnets, etc.— are also found in various localities. Germany is likewise extremely rich in mineral waters, including chalybeate, sulphurous, alkaline, saline, and warm of all kinds.

The quantity of minerals produced in 1900 is shown in the following table:

	Tons
Coal	109,290,200
Lignite	40,498,000
Iron ore	18,964,300
Zinc ore	639,200
Lead ore	148,300
Copper ore	747,700
Rock salt	926,600
Potassic salt	3,050,600
Gold, nickel, bismuth and other products	401,900
The total value was about	$315,000,000

Soils.— The alluvial soil of the Rhine valley is the richest in the country, and here the vine is extensively and profitably cultivated. The soils of the southern river valleys are also remarkable for their fertility. The great northern plain, although consisting of an alluvial glacial deposit, has a poor soil owing to the large admixture of Quaternary sands, necessitating careful tillage and artificial fertilization to attain any degree of productivity. With the exception of the hills and mountains, which are densely wooded, the rest of the country consists largely of extensive tracts of sterile plateau and moorlands.

Climate.— The climate of Germany is fairly uniform throughout, the lower latitude of the southern portions being compensated by greater elevation above the level of the sea. January is always the coldest month, its mean temperature being generally below freezing point, except on the North Sea coast, the northwestern plain, and the Upper Rhine valley. The mean temperature of the warmest month (usually June) generally ranges from 60° to 66° F. The range of mean annual temperature is from 36.3° on the Brocken to over 50° in the Upper Rhine valley and parts of Bavaria. The greatest annual rainfall is that of the Upper Harz region (67 inches); for Rhenish Prussia and Westphalia it is 41 inches, for the Upper Rhine valley from 23 to 27, and rather less for the Berlin region. The best climates are those of the Upper Rhine valley, and the valleys of the Moselle, Main, and Neckar.

Forestry.— About a quarter of the surface is under forest, the largest proportional amount being in Hesse-Nassau. The chief trees are the beech and oak, mainly in the west; pines, chiefly on the northern plain; firs, in the mountainous districts; birch and alder, chiefly in the north; larch, on the southern mountains; and chestnut, in the Upper Rhine valley. Forestry as an industry is under the protection of the state, conducted under scientific methods, and yields to Prussia, for instance, from forests and domains, an average annual revenue of $20,000,000.

Flora.— Germany belongs entirely to the region of the middle European flora, and is crossed by the northern limit of vine cultivation (about lat. 51°–52° N.). The total number of flowering plants in its flora is about 2,500.

Fauna.— There are three faunal zones — Alpine, Upper German, and Lower German — the first being the richest. The fauna is mainly a forest one, and includes 65 mammals and 225 birds. Notable species are the wolf, badger, mink, beaver, wild cat, wild boar, elk, bear, and one kind of tortoise.

Fisheries.— These are comparatively unimportant. The river waters abound with the salmon tribes, together with carp, pike, eel, roach, and perch, giving employment to some 20,000 persons, while about 12,000 persons are engaged in the deep-sea and shore fisheries, chiefly for cod and herring in the North and Baltic seas.

Land Tenure.— With the exception of the Mecklenburg grand duchies, unhampered free trade in land has been legally enacted throughout the German empire. Large estates are held in the northeast, while peasant proprietorship and small estates are general throughout the west German states.

Agriculture, etc.— Germany is becoming less and less an agricultural and more and more a manufacturing nation, but in many parts agriculture is still the main business of the population. About 65 per cent of the total area is under cultivation, and of this more than half is under the chief cereals, fully a sixteenth under other corn crops and leguminous plants, nearly a sixth under potatoes, turnips, sugar beet, cabbages, etc., while less than a fiftieth represents orchards and gardens. The empire does not now grow the cereals in sufficient quantity to meet its own requirements, but is becoming increasingly dependent upon imports, especially of wheat and barley from Russia, Hungary, Rumania, and North America. Of the chief cereals, rye occupies the largest area, and next in order come oats, wheat, barley. Spelt is grown in the south and maize also to a small extent. Buckwheat is a northern crop, and potatoes, though grown all over the empire, are most widely cultivated in

the north. Flax and hemp thrive best in the central mountainous districts. Hops are raised chiefly in Bavaria (Main valley below Nuremberg), Baden (Carlsruhe district), Hagenau district west of the Rhine, Würtemberg, and Posen; sugar beet in an extensive region from Leipsic to Brunswick, including Madgeburg and Halle, around Bautzen in the Breslau-Liegnitz district, near Danzig, Neu-Strelitz, Bromberg, Frankfort-on-the-Oder, etc.; tobacco chiefly in Baden, the Bavarian Palatinate, and Brandenburg. The yield of the principal crops in 1901–2 was as follows:

	Tons
Wheat	2,498,851
Rye	8,162,660
Barley	3,321,102
Oats	7,050,153
Potatoes	48,687,261
Hay	22,373,047

The chief wine-growing region is the Rhine valley from Baden to Cologne, with the valleys of the Moselle and the Neckar; but other important districts are the Main valley about Würzburg, the valley of the Saale in the Naumburg-Weissenfels district, the Elbe valley at Dresden, parts of the Rhine valley above Strasburg, and a small district north of Görlitz. The growing of vegetables and market gardening generally is most extensively carried on around Berlin, Dresden, Leipsic, Erfurt, Hamburg, Brunswick, and Düsseldorf. Fruit-growing is most successful in the middle and south of the empire, especially in Saxony, Franconia, and the middle Rhine valley.

Stock-raising.— Good horses are reared in the provinces of East and West Prussia, Mecklenburg, Holstein, and Hanover; cattle thrive best on the North Sea coast, in Franconia, the Vogtland, and the Alpine districts; sheep-breeding is declining, but good wool is still obtained from Saxony, Silesia, and Brandenburg. Swine are bred chiefly in Westphalia, Mecklenburg, Pomerania, Bavaria, and Prussian Saxony. The number of domestic animals in Germany in 1900 was estimated at: cattle, 18,939,692; swine, 16,807,014; sheep, 9,629,501; horses, 4,195,361; goats, 3,266,997.

Commerce.— The territory of the customs union known as the Zollverein now comprises the whole empire, with the addition of Luxemburg and the Austrian communes of Jungholz and Mittelberg, and with the exception of the free port of Hamburg, part of Cuxhaven, the free ports of Bremerhaven and Geestemünde, Helgoland, and some southern frontier communes in Baden. The total imports in 1901 were valued at $1,372,413,910, and the exports at $1,094,663,610. The chief imports were cereals, wool, timber, cotton, hides, silk, coal, cattle; and the chief exports were iron goods, drugs, coal, woolens, cottons, sugar, machinery, iron, silks, etc. The imports came mainly from the United States which led all other countries, Great Britain, Austria-Hungary, Russia, France, and Belgium, and the exports were sent chiefly to Great Britain, Austria-Hungary, Russia, United States, Netherlands, Switzerland, and France.

The foreign commerce of Germany is transacted mainly under reciprocal treaties, which have proved a source of much political dissension between native agriculturalists and manufacturers, the former aiming at prohibiting the importation of domestic commodities of foreign origin, and the manufacturers striving to maintain equal or favorable terms of reciprocity.

Manufactures.— The progress of the German manufacturing industry is without parallel among European nations, and is due in large measure to the great advance in technical education. The textile industries give employment to about a million persons, the chief branches being as follows: Cotton in Upper Elsass (Mühlhausen), Saxony (Chemnitz), Rhenish Prussia (München-Gladbach, Elberfeld-Barmen), Würtemberg (Reutlingen), Bavaria (Baireuth, Augsburg), Baden, and Silesia (government of Liegnitz); wool spinning in Rhenish Prussia, Saxony, Würtemberg, and Elsass; woolen cloth in the above districts and also in Lower Lusatia and southeast Brandenburg (Cottbus-Serau district); hosiery in Chemnitz, Glauchau, Plauen, Thuringia, Würtemberg, and Elsass; carpets in Berlin, Barmen, etc.; linen weaving on frontiers of Silesia and Bohemia, Saxony (Zittau), and the Bielefeld district; jute goods in Brunswick, Meissen, etc.; silk in Crefeld, Elberfeld-Barmen, Berlin, Aix-la-Chapelle, Baden, and Lorraine. Three or four hundred thousand persons are employed in the iron and steel manufacture. Its chief seats are: Rhenish Prussia and Westphalia from Düsseldorf to Dortmund, and the Aix-la-Chapelle district; Upper Silesia; and the extreme southern part of the Rhine province between Luxemburg and the Palatinate; but the iron works of Hanover, Saxony, Thuringia, Bavaria, and Würtemberg are also important. The smaller iron industries are chiefly carried on in Solingen, Hagen, Gevelsberg, Remscheid, Aix-la-Chapelle, Iserlohn, Lüdenscheid, Altona, etc. Over 300,000 men are employed in the machinery manufacture, mainly in Rhenish Prussia, Westphalia, Saxony (kingdom and province), Brandenburg (Cottbus to Seraub), Silesia, Bavaria, Elsass, etc. Cassel is the chief place for locomotives, and Berlin, Chemnitz, Dortmund, and Düsseldorf are the chief centres for steam-engines and machine tools. Ship-building is carried on in Bremen, Danzig, Elbing, Flensburg, Hamburg, Kiel, Lübeck, Rostock, Stettin, and Wilhelmshaven, and river steamers are built in Dresden, Mainz, Munich, and elsewhere. Other manufactures of importance are: Plate-glass (Rhenish Prussia, Westphalia, Silesia); bottle-glass (Saxony, Rhenish Prussia, Bavaria, Hanover, Lusatia, etc.); earthenware (Silesia, Hesse-Nassau); porcelain (Meissen, Berlin, Dresden, Silesia, Rhenish Prussia, Thuringia, etc.); bricks, chiefly in the north; tanning (especially Mainz, Worms, Kirn, Malmedy, Saxony); boots, and shoes (Pirmasenz, Mainz, Balingen, Offenbach, Thuringia, Saxony, Silesia); gloves (Saxony, Würtemberg, Berlin); fur goods (Leipsic); gold and silver, brass, and bronze wares; toys (especially Nuremberg and Thuringia); optical, medical, mathematical, musical, and other apparatus and instruments; telegraphic and electrical apparatus and machinery (Aix-la-Chapelle, Berlin, Breslau, Chemnitz, etc.); calcium carbide and acetylene; drugs; aniline and alizarine dyes; soap and candles; beet sugar (Saxony, Silesia, Rhenish Prussia, Thuringia; trade centres are Magdeburg, Breslau, Berlin, Cologne); brewing (best in Bavaria, Berlin, Dresden); distilling; furniture, cigars (Saxony); lithographic stones (Solnhofen); etc. The cottage system of in-

dustry is gradually being displaced by the factories, but it is still common in some branches.

Shipping and Navigation.— The mercantile marine is steadily increasing in numbers, and now includes the fastest transatlantic steamers. On 1 Jan. 1901 it comprised 3,883 vessels (registered tonnage, 1,941,645), of which 1,390 (registered tonnage, 1,347,875) were steamers. The principal seaports of Germany are Hamburg, Bremen, Lübeck, Stettin, Kiel, Danzig, and Königsberg. In addition to the figures given, are 22,564 vessels engaged in coasting trade and inland navigation, 21,945 of which are registered with a total of 3,370,447 tons.

Railways.— The length of railway controlled by the Union of German Railways in 1900 was 55,963 miles, of which 19,693 miles were in Austria-Hungary, Netherlands, Luxemburg, Rumania, etc. The total railway mileage of Germany in 1900 was 36,270, of which Prussia had 26,672, Bavaria 4,192, Saxony 1,878, Baden 1,210, Würtemberg 1,163, and Elsass 1,155. Of the total 28,547 miles were state lines.

Canals.— The excellent river system has been supplemented, especially in recent times, by the construction of numerous canals. Throughout the empire the rivers are naturally navigable for 5,774 miles; there are 1,458 miles of canalized rivers, and 1,519 miles of canals. One of the most modern and most important canals is the Kaiser Wilhelm Canal (q.v.) connecting the North Sea and the Baltic, which was opened for traffic 19 June 1895.

Posts, Telegraphs, and Telephones.— With the exception of Bavaria and Würtemberg, the postal and telegraphic services of Germany are united under an imperial postal district. Throughout the German empire in 1901 17,049 towns had telephonic communication.

Money, Weights, and Measures.— By the law of 4 Dec. 1871 a uniform gold standard was introduced for the whole German empire, it being decreed that out of one pound of fine gold 139½ pieces of an imperial gold coin should be struck, the tenth part of which should be called a mark, and divided into 100 pfennige; that an imperial gold coin of the value of 20 marks should also be struck at the rate of 69¾ to 1 pound of fine gold; and that these coins should be made of an alloy containing 900 parts of gold and 100 parts of copper. The same law ordered the adoption of the mark as the general unit of the German coinage, commencing 1 Jan. 1875. By the supplementary law of 6 May 1873 it was enacted that two-mark and five-mark pieces should also be issued, the former in silver and the latter partly in gold and partly in silver. The 10-mark piece (*krone*) and 20-mark piece (*doppelkrone*) are nearly equal in value to the English half-sovereign and sovereign respectively. The old silver thaler (=3 marks) is still legal tender. A mark is equal to 23 cents in United States gold.

Since 1 Jan. 1872 the French metrical system of weights and measures has been in force throughout the German empire. It had previously been adopted by a law of the diet of the North German Confederation, and under the constitution of the new German empire it was arranged that the new system of weights and measures should be introduced into the south German states according to the terms of separate treaties previously concluded by them with the North German Confederation. As the values of the different units of the metric system are given in the article WEIGHTS AND MEASURES, it will be sufficient here to give the German names of the various denominations of that system:

Measures of Length —

Das Millimeter or Der Strich	= the Fr.	Millimètre.
" Centimeter or " Neuzoll	= "	Centimètre.
" Decimeter	= "	Décimètre.
" Meter or Der Stab	= "	Mètre.
" Dekameter or Die Kette	= "	Decamètre.
" Kilometer	= "	Kilomètre.

The new German mile is equal to 7,500 metres.

Measures of Surface —

Das Quadratmeter or Der Quadratstab	= the Fr.	sq. Mètre.
" Ar	= "	Are.
" Hektar	= "	Hectare.

The unit of the measures of capacity is *das Kubikmeter* or *der Kubikstab* = the French *stère.*

In liquid measure the following terms are used:

Das Liter or Die Kanne	= the Fr.	Litre.
" Hektoliter or Das Fass	= "	Hectolitre.

A measure equal to half a liter is called a *Schoppen,* and one equal to 50 liters a *Scheffel.*

Measures of Weight —

Das Milligramm	= the Fr.	Milligramme.
" Decigramm	= "	Centigramme.
" Centigramm	= "	Décigramme.
" Gramm	= "	Gramme.
" Dekagramm	= "	Décagramme.
" Kilogramm	= "	Kilogramme.

Half a kilogramm is one *Pfund;* 50 kilogramms, or 100 *Pfund,* make one *Centner;* and 1,000 kilogramms one *Tonne.*

Banking.— The *Reichsbank* or Imperial Bank founded by the *Reichstag* in 1875 is the depository of the imperial treasury, the leading bank of issue, and of imperial banking operations. At its establishment it shared the authority to issue bank-notes with 31 other banks, which number by 1900 had diminished to 7, the Bank of Baden, Bavarian Bank of Issue, the Bank of Brunswick, Bank of Frankfort, Bank of Saxony, South German Bank, and Würtemberg Bank of Issue. The total business of the Imperial Bank in 1900 was $44,982,000,000, its loans on securities alone in that year amounting to $209,400,000. One of its most important branches is the clearing house department. There are clearing houses also in the most important cities, numerous private banks, people's banks, agricultural mortgage banks, and about 150 joint stock banking companies with a total capital in 1900 of over $428,400,000.

Constitution and Government.— The constitution of the German empire is based on the decree of April 16, 1871. The presidency of the empire is the privilege of the king of Prussia, to whom belongs the hereditary title of German Emperor. The legislative authority is vested in the Bundesrath, or Federal Council, and the Reichstag, or Imperial Diet. The prerogatives of the emperor are to represent the empire in its relation to other states, to declare war and conclude peace in the name of the empire, to contract alliances and conclude treaties with foreign states, to accredit and receive ambassa-

dors. The assent of the Bundesrath is, however, necessary to a declaration of war, unless the imperial territory be invaded, or its coasts attacked. The emperor has also the supreme command of the army and navy, summons, opens, prorogues, and concludes the Bundesrath and Reichstag, appoints and dismisses officials of the empire, and superintends the consulate.

The Bundesrath consists of 58 representatives of the members of the empire. Of these 17 are returned by Prussia, 6 by Bavaria, 4 each by Saxony and Würtemberg, 3 each by Baden and Hesse, 2 each by Mecklenburg-Schwerin and Brunswick, and 1 each by Saxe-Weimar, Mecklenburg-Strelitz, Oldenburg, Saxe-Meiningen, Saxe-Altenburg, Saxe-Coburg-Gotha, Anhalt, Schwarzburg-Rudolstadt, Schwarzburg-Sondershausen, Waldeck, Reuss-Greiz, Reuss-Schleiz, Schaumburg-Lippe, Lippe-Detmold, Lübeck, Bremen, and Hamburg. Alsace-Lorraine (Elsass-Lothringen) is represented in the Bundesrath by four commissioners without votes. Every year or every session standing committtees of the Bundesrath are appointed by the members from their own number: (1) for the army and fortifications; (2) for the navy; (3) for the customs and other imposts; (4) for trade; (5) for railways, posts, and telegraphs; (6) for justice; (7) for finance; (8) for foreign affairs; and (9) for the affairs of Alsace-Lorraine.

The Reichstag is elected by secret voting in all the states, every German above 25 years of age having a right to vote in the state in which he resides. Members of the army and navy cannot exercise their right of voting while their period of service lasts. Anyone may be returned to the Reichstag who has the right of voting and who has belonged for at least a year to one of the states. As a rule, one member is returned to the Reichstag for every 100,000 of the inhabitants of each state, but every member of the empire sends at least one deputy, even though its population is under that number. In 1902 the Reichstag consisted of 397 members, namely: 236 from Prussia and Lauenburg, 48 from Bavaria, 23 from Saxony, 17 from Würtemberg, 15 from Alsace-Lorraine, 14 from Baden, 9 from Hesse, 6 from Mecklenburg-Schwerin, 3 each from Saxe-Weimar, Oldenburg, Brunswick, and Hamburg, 2 each from Saxe-Meiningen, Saxe-Coburg-Gotha, and Anhalt, and 1 each from the other states. Proposals of laws are laid before the Reichstag by members of the Bundesrath, or by commissaries appointed by it. Every member of the Bundesrath has the right of appearing in the Reichstag, and has a right to be heard there at any time to represent the view of the government. No one can at the same time be a member of the Bundesrath and the Reichstag. The Reichstag lasts for five years. To dissolve it within that period a decree of the Bundesrath and the assent of the emperor are necessary. In case of a dissolution new elections must take place within 60 days, and the new Reichstag must meet within 90 days. To render an imperial law (*Reichsgesetz*) valid there must be a majority of votes in its favor both in the Bundesrath and in the Reichstag, and nothing else is required. Changes in the constitution may be effected in the same way. Disputes between two or more states of the empire, in so far as the common law courts are incompetent to deal with them, may be settled by the Bundesrath on an appeal being made to that body by either of the parties to the dispute.

The empire has the sole right of legislating on all matters connected with the army and navy, the finances of the empire, commerce, posts and telegraphs (except in Bavaria and Würtemberg), railways in so far as they are deemed necessary for the defense of the country, and proposed modifications of the constitution of the empire. Certain other matters are left largely to the management of the individual states.

Finance.— The total revenue and expenditure of the empire for 1902 were estimated to balance at $540,340,764. The chief sources of revenue are the customs, excise duties on tobacco, sugar, salt, and spirits in all the states, an excise duty on beer except in Bavaria, Würtemberg, Baden, and Elsass, stamps, posts, and telegraphs except in Bavaria and Würtemberg, railways, and the *Matricular Beiträge* paid by the federated states to the imperial treasury in proportion to population, but with additions in the case of those states which administer their own posts, telegraphs, and beer duties. The bonded debt of the empire in 1900 was $528,655,000, against which are to be set the invalid fund of about $98,000,000, and the war treasure fund of $30,000,000. When the German empire had been in existence six years its debt amounted to the insignificant sum of 16,300,000 marks. In 1888, when the old emperor died, it was only 721,000,000 — not very large for a nation of importance. Two thirds of the present debt has been used for naval and military purposes, the rest for civil administration, etc. In 1886 the naval and military estimates amounted to 497,000,000 marks. In the following year they rose to 632,000,000 marks. In 1903 the estimates rose to 972,000,000 marks. From 1897 to 1903 the yearly interests to be paid for loans invested in the army and navy rose from 61,000,000 to 83,000,000 marks.

Army and Navy.— Service in the army or navy is obligatory on every German capable of bearing arms from the age of 17 to that of 45. Within this period seven years must be passed in the standing army or in the fleet (generally the years between 20 and 28) two of them in active service (three for cavalry and horse artillery). The remainder of the seven years are passed in the reserve. The next five years are passed in the first class or "ban" of the *Landwehr* or *Seewehr* (land or sea defensive forces); service continuing in the second class or ban up to the age of 39. Of young men becoming liable to service every year, only a certain number chosen by lot join the regular army; the remainder enter the *Ersatztruppen* or depot reserve, in which service lasts for 12 years. The *Landsturm* consists of all from 17 to 45 who are not otherwise in service; being divided into two bans or sections; the first comprising men from 17 to 39, the second those from 39 to 45. This force is only called on for active service in case of an invasion of the country. Young men above 17 years of age, who are able to pass an examination on general subjects, and who volunteer for active service

THE GERMAN EMPEROR AND HIS FAMILY.

in the army, and agree to equip and maintain themselves during active service, are admitted into the reserve after one year's service. This privilege is also granted to teachers in primary schools, and Roman Catholic priests ordained before a certain age are exempt from active service and drill altogether.

Organization and Strength of the Army.— The German army consists of 23 army corps, of which three are furnished by Bavaria, two by Saxony, one by Würtemberg, and the remaining 17 by Prussia and the other states. The Bavarian corps are numbered separately, and in time of peace form a separate army under the king of Bavaria. The Prussian Guard Corps, with headquarters at Berlin, is recruited from all Prussia, but the others have districts allotted to them. The corps are grouped into five inspections, each comprising from three to five corps. The following is a list of the headquarters of the various corps arranged in inspection groups, the first mentioned town in each being the headquarters of the inspection: Berlin — Königsberg, Stettin, Altona, Hanover, Danzig; Dresden — Posen, Breslau, Dresden, Leipsic; Hanover — Münster, Coblentz, Cassel, Stuttgart, Frankfort-on-the-Main; Munich — Berlin, Magdeburg, Munich, Würzburg, Nuremberg; Carlsruhe — Carlsruhe, Strasburg, Metz. Each corps has ordinarily two divisions, each comprising infantry, cavalry, and field artillery. Each army corps district is divided into two divisional districts, and from four to six brigade districts. Each brigade district is subdivided into from one to six *Landwehr* districts, and the total number of these district commands is 293. In case of war the army corps are brought up to their full complement of men by drawing on the reserve and the *Landwehr.*

The following table shows the total strength of the German army on the peace footing in 1900:

	Officers	Rank and File
Infantry	13,314	335,797
Cavalry	2,406	56,819
Field Artillery	2,980	52,622
Foot Artillery	872	18,730
Pioneers	571	12,504
Train	322	6,213
Railway, Telegraph, and Balloon Service	237	5,175
Others	3,142	3,276
Total	23,844	491,136

Under the Army Act of 1899 the peace effective was to be gradually increased, and in 1903 reached 605,978; as an interesting comparison, in 1872 it was 350,000. The war strength is now estimated at about 3,000,000 men.

Strength of the Navy.— The German war fleet has been greatly increased in recent years and the rate of increase is likely to be maintained for some time. By the law of 14 June 1900 the effective strength (excluding torpedo boats and some others) has been fixed as follows: A fighting fleet comprising 2 admiral's flag ships and 4 squadrons, each of 8 ships of the line, 8 large and 24 small cruisers, a fleet for service abroad of 3 large and 10 small cruisers; a reserve of 4 ships of the line, 3 large and 4 small cruisers. The present strength of the imperial navy is as follows: 14 battleships of the line, 8 armored coast defense ships, 13 armored gunboats, 11 large cruisers, 25 small cruisers, 5 gunboats, 16 school ships, and 13 others, besides torpedo boats. The personnel of the navy is recruited from the maritime and semi-maritime population of the empire. The total is at present about 30,000 men.

Colonies.— The colonial policy of Germany dates from 1884 since when it has established protectorates over extensive regions in Africa, and over several islands in the Pacific Ocean. Its foreign dependencies have an estimated area of 1,027,820 square miles, and an estimated population of 13,087,000. The African dependencies include Togoland, estimated area 33,700 square miles, population 900,000; Kamerun, area 191,130 square miles, population 3,500,000; German East Africa, area 384,180 square miles, population 8,000,000; German Southwest Africa, area 322,-450 square miles, population 200,000. Total of African dependencies — acquired between 1884 and 1890 — 931,460 square miles, population 12,600,000. The Pacific dependencies acquired between 1884 and 1899 comprise under German New Guinea, Kaiser Wilhelm's Land, area 70,000 square miles, population 110,000; in addition there are the Bismarck archipelago, area 20,000 square miles, population 188,000; Caroline Islands and Palan Islands, 560 square miles, population 40,000; Marianne Islands, 250 square miles, population 2,000; Solomon Islands, 4,200 square miles, population 45,000; Samoan Islands, 1,000 square miles, population 29,100; and Marshall Islands, area 150 square miles, population 13,000. Total of Pacific possessions 96,160 square miles, population 427,000. In 1897 Germany seized Kiao-Chau on the east coast of the Chinese province of Shan-tung, and in 1898 declared a protectorate over the town, harbor, and district, which has an area of 200 square miles, and an estimated population of 60,000. With the exception of the Marshall Islands, which are administered by an imperial commissioner, the colonies are under the direct rule of imperial governors with almost autocratic powers. The colonies have not yet proved self-supporting and are assisted by government grants which in 1901 amounted to about $7,400,000.

Ethnology.— The Germans are descendants of Teutons, Vandals, Franks, Allemanni, and the numerous tribes which figure in Roman history as dwelling within the limits of Germania (see paragraph on *History*). From language and other indications they are supposed to have migrated in prehistoric times from Upper Asia, passing by the Caucasus and the north of the Caspian and Euxine seas to Europe. There is no mention of this migration in the national legends, and the people considered themselves as autochthones, and were thus regarded by the Romans. They are usually classified into Low or northern Germans, and High or southern Germans. Within the boundaries where they constitute the compact mass of the population and include the German-speaking Dutch and Flemings, their numbers are estimated at 56,000,000. The German empire also includes over 4,000,000 natives of foreign extraction, comprising Poles, an antagonistic element numbering about 3,000,000 dwelling chiefly in Posen

and Silesia, northeast Prussia; Danes, found in Schleswig; Wends in Brandenburg, Silesia, and Saxony; Czechs in Silesia; Lithuanians in East Prussia; French in Alsace-Lorraine; and about 570,000 Jews distributed through the empire. The dividing line between Low and High Germans may be drawn from lat. 50° 30′ N. in western Germany to lat. 52° 30′ N. on the eastern frontier. In physical development the Germans are superior to either the Latin or Slavic race, while surpassed in agility by the former and in power of endurance by the latter. Their frame and their muscular development are strong, almost heavy. Among the lower classes of the rural and laboring population, stoutness and strength often approach to clumsiness, which is heightened sometimes by a servile bearing and a certain uneasiness and want of self-reliance. The northerners generally are taller and of better shaped features and limbs than the southerners. The blonde complexion prevails only in the north; in central and southern Germany light or dark brown is more frequently found. The prominent features of the German national character are honesty, faithfulness, valor, thoughtfulness perseverance, and industry. The German is patient, conservative, and inoffensive; he favors a moderate enjoyment of the pleasures of social life, but sometimes, or rather in some portions of Germany, this is carried to excess and the complaint has been heard that popular movements in favor of liberty have been drowned in the social cup. Of a scientific turn of mind, the Germans have largely promoted the progress of human knowledge. There is scarcely a branch of science in which Germans have not excelled. In the fine arts also they occupy one of the highest ranks among nations. The German artisan is highly valued for his dexterity and steadiness.

Sociology.— The element of a strong national feeling was long lacking in the German character, and of no other country in Europe is it so true as it is of Germany, that it is the product of conscious will. German nationality, German life, German material civilization, have been developed by a succession of great men who were at first electors of Brandenburg, then kings of Prussia, and finally emperors of Germany. Other nations have slowly crystallized; this one was welded, like a sword. The Anglo-Saxon race believe in a nation which unfolds its own genius, attains to liberty, and governs itself by constitutional forms. The Latin race likes an orderly, logical, ready-made system. But here is a powerful nation which is a historical yet artificial creation, the work of a house of hero rulers of the Carlyle type. Paternalism flourishes in Germany because Germany is the child of paternalism. Its history has not been, as England's, the history of a people struggling against the royal prerogative to secure their freedom and establish their political institutions, but of a people led forward by strong rulers to a foreseen end. Not the rights of the individual, but the good of the state and the bonds of duty, have been the vital forces of progress. That is why the emperor can talk to his subjects as he does of obedience, loyalty, discipline, the greatness of his ancestors, and what he himself proposes to do, without making himself ridiculous to them.

The corner-stone of the Hohenzollern nation-building has been military power. "The world does not rest more securely on the shoulders of Atlas," said Frederick the Great, "than the Prussian state on the shoulders of the army." By the army the elector of Brandenburg, Frederick III., won the right to crown himself Frederick I., king of Prussia, owing no allegiance to the house of Hapsburg. By the army his grandson, Frederick the Great, raised his little kingdom to the rank of a great European power. By the army Emperor William I. brought about national unity. By army and navy Emperor William II. means to make real his conception of a world-power.

But Germany is not great by its army alone. In peace as in war, Prussia has developed efficiency. Its rulers have taken care to bring about conditions favorable to economic and intellectual progress. In these respects also they have planned and promoted what has come to pass. Government has meant to them the intelligent direction of the national life. "The strength of North Germany," said Arminius long ago, "lay in this, that the idea of science governed every department of human activity there." The same is true to-day. See GERMAN ART; GERMAN LANGUAGE AND LITERATURE.

Population.— Statistical estimates for the German empire place the population on 1 July 1903 at 58,549,000, against 57,708,000 and 56,862,000 on 1 July 1902 and 1901, respectively.

From these figures it appears that the population has increased 841,000, or 1.46 per cent in 1903, while the increase of 1902 over 1901 was 846,000, or 1.49 per cent. The census of 1 Dec. 1900 showed a population of 56,367,178. Thus, according to official estimates, the increase in two and one half years is 2,180,000. In the last 10 years the population has increased 7,800,000, in the last 20 years 12,500,000, and since the formation of the German empire 17,500,000.

The excess of female births in proportion to male is 6 per cent, and the number of women exceeds the number of men by 3.2 per cent. The census of 1900 returned 27,731,067 men and 28,613,947 women or an excess of 882,430 women.

Emigration.— The German as an individual is in many instances more favorably inclined toward other countries than his own. This probably results from an abstract idealism with which many Germans seem imbued. Among the great number of emigrants from Germany to other continents, there are thousands with whom the motive for voluntary expatriation is not social or individual misfortune, but merely a visionary longing after an ideal state of society. The United States receives the bulk of German emigration. It is estimated that during the 19th century more than 6,000,000 emigrants left Germany, of which number the United States received 90 per cent, the rest being divided among South American states, Australia, Africa, and Asia. In recent years emigration has greatly decreased, due to improved social and economic conditions at home. See GERMANS IN THE UNITED STATES; GERMANY, MODERN.

Education.— Throughout the empire education is general and compulsory, the laws providing for the establishment of *Volksschulen* or primary schools in every town and village.

Kindergartens are carried on by private enterprise only. The *Volksschulen* are supported by the local rates, and parents are compelled to send their children, from the age of 6 to 14, to these or other schools, such as the *Bürgerschulen* and *Höhere Bürgerschulen*, middle-class schools of the towns which rank above the normal or primary schools. *Fortbildungsschulen*, or continuation schools, are provided for children of the working classes, and are open on evenings and Sundays for those who wish to pursue their studies; they provide for two- and three-year courses and give technical instruction. Secondary and advanced education is conducted along the lines of social distinctions, and the schools of this grade are constituted with regard to the business or professional careers which it is intended the pupils should pursue. They comprise the *Oberrealschulen* and *Realschulen*, in which the classics are displaced in favor of modern languages; the *Realgymnasia*, in which Latin but not Greek is taught, more attention being devoted to modern subjects; *Gymnasia*, the most fully developed classical schools, preparing pupils for the learned professions and the universities in a nine-years' course; and *Progymnasia* and *Realprogymnasia*, modifications of the latter two. Higher education for girls is provided by the *Höhere Tochterschulen*. In addition to these there are *Gewerbeschulen*, or technical high schools, polytechnics, schools of agriculture, academies of forestry, schools of mining, of architecture and building, of art and art industry, of music, and 21 universities. With the exception of Münster University, which has faculties of theology and philosophy, all the rest have four faculties: theology, jurisprudence, medicine, and philosophy. In 14 universities the faculties of theology are Protestant; in three, Bonn, Breslau, and Tübingen, Protestant and Roman Catholic; in four, Freiburg, München, Münster, and Würzburg, Roman Catholic.

Religion.— Religious liberty is provided for under the Constitution of the empire, the repeal of the statute of 1872 by the Reichstag, 10 March 1904, having removed the last interdiction which the law placed upon Roman Catholics. According to the census of 1900, 35,231,104, or 62.5 per cent of the population, are Protestants and 20,327,913 or 36.1 per cent, Roman Catholics. The Protestants are divided by their confessions into Reformed and Lutheran bodies. Among Roman Catholics there are two seceding bodies, the German Catholics (q.v.) and the Old Catholics, who repudiated the dogma of the Pope's infallibility in 1871 and now number about 50,000.

Judiciary.— Since 1879 there exists a uniform system of law courts throughout the empire, although the courts are subjected to state and not to imperial control. There are four grades of courts, the lowest court of first instance being the *Amtsgerichte*, presided over by a judge to try petty civil and criminal cases. Above these district courts are the *Landesgerichte*, territorial courts, exercising a revising jurisdiction over the lower courts and also a more extensive original jurisdiction in both civil and criminal cases. In criminal cases five judges sit, four votes being necessary for a conviction. *Schwurgerichte*, jury courts, are also held periodically, consisting of 12 jurors and three judges. The *Oberlandesgericht* is the first court of second instance, divided into civil and criminal senates, the criminal senate consisting of seven judges. Bavaria alone, by special permission, has an *Oberstes Landesgericht* with 22 judges. The *Reichsgericht* is the supreme or imperial court, and sits at Leipsic. It has 92 judges chosen by the Bundesrath and appointed by the emperor; four criminal and six civil senates; and exercises an appellate jurisdiction over all inferior courts, and an original jurisdiction in cases of treason.

Local Government.— With the exception of Mecklenburg, which has a mediæval diet of landholders and city magistrates, all the monarchic states have modernized constitutional governments. The federal principle exists throughout the empire and the rights of the smaller states are guarded by the distribution of votes in the federal council. The free cities (q.v.) of Hamburg and Bremen have mixed governments, while Lübeck is governed by a conservative democracy. The system of local self-government established in Prussia (q.v.) by the cities' ordinance of 1808 is typical throughout the various states, which exercise a general supervision over the enforcement of imperial laws as affecting local affairs.

Poor-relief.— Bavaria and Alsace-Lorraine have independent poor-law legislation; all the other states have adopted the settlement law passed by the Reichstag in 1870. Settlement for purposes of poor-relief is obtained by a residence of two years in a commune, each commune providing for its own poor. Anyone entitled to poor-relief may obtain it from a commune in which he may happen to be, that commune recovering expenses from the settlement commune of the applicant. *Landarme* or applicants without settlements are provided for by the government of their native state.

History.— The territory to which the ancients gave the name of Germany was much larger than the modern territory of the same name. It comprised to the north Denmark, Sweden, and Norway, and on the south Pliny makes it extend as far as the Alps, but up till the time of Cæsar the southern boundary was the Danube. The boundary on the east with Sarmatia and Dacia is not exactly defined, and on the west the Rhine was only a nominal or formal boundary. The Germans had extended beyond the Rhine in the time of Cæsar, who gives this boundary. The Belgæ and the Treviri, who occupied Alsace, were at least mixed races; and Ptolemy gives the names Germania Superior and Germania Inferior to two divisions of Belgica extending along the west bank of the Rhine, from the sea to the Sequanian territory, near Basel. These divisions are also mentioned by Tacitus as forming two of the six divisions of Gaul. Germany east of the Rhine was called Germania Magna or Barbara. Pliny enumerates 68 tribes and 94 towns in Germany.

Germany, especially the southern part, was covered in the time of the Romans by extensive marshes and forests which were inhabited by the elk, the urus, the bear, the wolf, the boar, the wild cat, and the deer. The population was large, however, particularly in the north and east, the chief indication of which is the num-

ber of the armies, or rather of the armed tribes which these districts from time to time sent out, and by which at length the Roman empire was overwhelmed.

Tacitus classifies the German nations into three groups, Ingævones, Herminones, and Istævones. These divisions are said to be named from the three sons of Mannus. The first inhabited the shores of the ocean, the second the interior, the third the south and east, but their limits are not defined.

The first distinct appearance of the Germans on the stage of classical history occurs 113 B.C., when the Teutons, a German people, appeared along with the Cimbri, supposed to be a Celtic one, on the frontiers of Gaul, defeated the Romans in several battles, and after the Cimbri had invaded Spain, were joined by the Ambrones, a people of Sarmatia, and continued to ravage Gaul. They were defeated by Marius near Aix (Aquæ Sextiæ) 102 B.C., when 100,000 are said to have been slain and 80,000 or 90,000 made prisoners. A small number who escaped, about 6,000, are supposed to have settled in the north of Gaul and become the ancestors of the Ædui. In 58 B.C. Ariovistus, king of the Suevi, who had crossed the Rhine and with an army of 120,000 Germans had subdued the greater part of eastern Gaul, was defeated by Cæsar and forced to recross that river. In 55 and 54 B.C. Cæsar himself crossed the Rhine, but effected no permanent settlement. He acquired an accurate knowledge only of the tribes nearest the Rhine, the Ubii, Sicambri or Sygambri, Usipetes, and Tencteri. He enlisted Germans in his army, both against the Gauls and against Pompey. Of the Germans with whom he did not become acquainted, he was informed that they lived more by hunting and pasture than by agriculture, held their fields in common, and prevented the approach of foreign nations by devastating their borders.

The civil wars diverted the attention of the Romans from Germany. The Confederacy of the Sicambri made inroads into Gaul with impunity, and Agrippa transferred the Ubii, who were hard pressed by the Suevi, to the west side of the Rhine. But the Sicambri having defeated Lollius, the legate of Augustus (16 B.C.), the emperor himself hastened to the Rhine, erected fortifications along the bank of this river to oppose the progress of the enemy, and gave his stepson Drusus the chief command against them. This great general was victorious in several expeditions and advanced as far as the Elbe. Tiberius after him held the chief command on the Rhine during two years and exercised more cunning than force against the Germans. He induced them to enter the Roman service. The bodyguard of Augustus was composed of Germans and the Cheruscan Arminius was raised to the dignity of knight. Tiberius having received the chief command a second time (4 A.D.), advanced to the Elbe. Germany had now been subdued by the successes of Drusus and Tiberius from the Rhine to the Weser, and Augustus had determined to introduce into it the regular administration of a Roman province. For this purpose he selected P. Quintilius Varus, who in accordance with his instructions proceeded to introduce the Roman rule; but these orders were either premature or were rashly executed. The Germans revolted under the leadership of Arminius, the Cheruscan already referred to, who had acquired a knowledge of military tactics in Rome. Besides the Cherusci, the Marsi, the Chatti, and the Bructeri joined the revolt. Arminius concocted his plans with a subtlety which speaks volumes for the vaunted fidelity of the Germans. By his recommendations the Germans obeyed all the orders of Varus, who had taken up his quarters on the banks of the Weser. Arminius and the other chiefs visited his camp on friendly terms.

Varus was induced by their recommendations to divide his troops. In the meantime a distant tribe was induced to revolt. Varus marched against them while his pretended allies went to collect their forces. He had entered the Teutoberg Forest without suspicion of danger with three legions, when he was suddenly attacked by the combined forces of the Germans, and after three days' fighting his army was almost completely destroyed (A.D. 9). He himself put an end to his life. The fortress of Aliso, erected by Drusus, to which a few had escaped, was afterward taken and destroyed and the Romans lost all their possessions east of the Rhine. The Cherusci now for a time became the principal nation of Germany. Germanicus after suppressing a revolt among the legions of the Rhine led them against the Germans and in a succession of campaigns avenged the defeat of Varus by ravaging the country of the Marsi and the Chatti and defeating the Cherusci under Arminius (A.D. 14–16), but he failed to recover the Roman ascendency in Western Germany. The wars which broke out among the Germans themselves, however, enabled the Romans to establish themselves in the southwest. Maroboduus, who had been sent to Rome as a hostage, and educated at the court of Augustus, at the head of some Suevian tribes, had subdued or expelled the Boii, who inhabited Bohemia and part of Moravia, established the Marcomannic kingdom, and organized the neighboring tribes into a league for defense against the Romans which became known as the Marcomannic confederacy. Augustus despatched Tiberius against Maroboduus, but the revolt of the Cis-Danubian provinces compelled Tiberius to make peace with him. Afterward the Marcomannic confederacy excited the jealousy of the Cherusci, and a war ensued which ended (A.D. 17) in the defeat of the Marcomanni. Maroboduus besought the assistance of Rome, and Drusus was sent to mediate a peace; but in A.D. 19 on some new offense Drusus was preparing to invade the country of the Marcomanni when Catualda, a chief of the Gothones whom Maroboduus had exiled, invaded and conquered it. Catualda was himself overcome and expelled by the Hermunduri. After this the Marcomanni were for a time dependent on the Romans, though with a king of their own.

The Romans had during this period, or from about A.D. 16, commenced to establish themselves on the southwest between the Upper Rhine and the Upper Danube. Here they formed a province called the Agri Decumates, peopled by Gauls, Germans, and Romans and subject to tribute. It was ultimately included in Rhætia and protected by a wall dividing it from the free Germans, but this proved an ineffectual protection against the incessant attacks to which it was subject during the decline

of the empire. The Cherusci after the loss of their great leader Arminius, A.D. 21, fell from their high rank among the German nations. Weakened by internal dissensions they were conquered by the Chatti, who now rose into importance, and sank into an insignificant tribe to the south of the Hercynian Forest. They appear again in the Frankish confederacy in the 4th century. The Chatti made repeated incursions across the Rhine which it required the force of more than one Roman emperor to restrain. They were also absorbed in the Frankish confederacy, as well as a colony of the Sicambri which Tiberius had transplanted to Gaul, and settled between the banks of the Lower Meuse and the Rhine. The Frisians, who had early entered the Roman alliance and remained faithful to it till A.D. 28, rose and expelled the Romans in consequence of the oppression of Olennius, the Roman governor. Corbula attempted to subdue them A.D. 47, but was recalled before he had achieved a decisive success.

The Batavi, a colony of the Chatti who left their homes in consequence of internal broils and occupied an island at the mouth of the Rhine, became allies of the Romans whom they furnished with soldiers, particularly with cavalry. They revolted A.D. 69 in the reign of Vitellius, and were with difficulty subdued. Domitian (A.D. 84) undertook an expedition against the Chatti and constructed a frontier wall between the free Germans and those subject to Rome. The Marcomanni had in the meantime been extending their dominion and had come into contact with the Romans on the Danube. Domitian asked their assistance according to treaty, in his war with the Dacians, and on their refusal went to war with them. Being defeated by the Marcomanni he was obliged to make a humiliating peace with Decebalus, king of Dacia.

As the aggressive force of the empire abated it continued to be more and more subject to the incursions of the Germans in Gaul, in Rhætia, in Noricum, and Pannonia. The Marcomanni were kept in check by Trajan and Hadrian, but being pressed by the migrations of other German tribes, they invaded the Roman provinces in 166, and commenced the Marcomannian war which was continued with a short interval till 188, when Commodus purchased peace of them. After this time their inroads increased in boldness and in the reign of Aurelian they penetrated into Italy and reached as far as Ancona. From this time they began to decline in importance, and the last mention of them is among the hordes of Attila. Two new combinations of German tribes — the Alemanni and the Franks — began soon after the termination of the Marcomannian war to threaten the Roman dominion on the west banks of the Rhine, and these incursions went on increasing till by the end of the 5th century the Germans had conquered Gaul, Italy, Spain, and part of Africa, having established a new kingdom on the ruins of Carthage. This great movement is called the migration of the nations. The Saxons, Frisians, and Angles toward the close of this period began their invasions of Britain. After this migration Germany itself continued in a divided state till it was conquered by Charlemagne. From the establishment of the Frankish kingdom of Clovis till the end of the Carlovingian dynasty the most important events of German history will be found in connection with the history of France (q.v.).

The deposition of Charles the Fat in 887 separated Germany from France; and Arnulf, an illegitimate descendant of Charlemagne, acceded to the crown of the former country. He was crowned emperor in 896 after a victory over Berengarius, Duke of Friuli. He died in 899, and was succeeded by his infant son Louis, who was proclaimed King of Lorraine in 900, assumed the title of emperor in 908, and as such is designated Louis IV. He died in 911, and with him the German branch of the Carlovingian dynasty became extinct. The German nations in their general assembly or diet chose Conrad, Count or Duke of Franconia, as his successor. He died in December 918 of a wound received in battle with the Huns. In 919 Henry the Fowler, Duke of Saxony, was elected. He invaded and annexed Lorraine which was now as afterward disputed between France and Germany. He extended the empire by successful wars against surrounding and less civilized peoples — the Huns, Vandals, Danes, and Bohemians — and he defeated the Hungarians, to whose incursions Germany was at this epoch subject, at Merseburg in 934. He was succeeded by his son Otto the Great in 936, who completed the conquest of Bohemia (950), invaded Lombardy, and was proclaimed King of Italy (951); after deposing Berengarius a second time he received the Italian crown at Milan (961); and revived the empire of Charlemagne and received the crown of the Holy Roman empire from the Pope 2 Feb. 962. He died in 973 and was succeeded by his son Otto II., who had been crowned emperor by the Pope in his father's lifetime. In 976 Otto deprived Henry of Bavaria, with whom he had been engaged in war, of his duchy. He also had a successful war with Lothaire, king of France, for the possession of Lorraine. He attempted the conquest of Calabria in 981, and held a diet at Verona in 983, at which his son Otto III. was declared his successor. He died in Rome the same year. Otto III., who was in his fourth year when he succeeded his father, was crowned by the Pope in 996. He held a diet at Rome in the same year and another at Aix-la-Chapelle in 1000. In January 1001 he defeated the Saracens in Italy. He died in 1002. Henry II., Duke of Bavaria, surnamed the Saint, the hereditary heir of the Saxon line, succeeded after a contest with Herman, Duke of Suabia, a rival claimant of the crown. He had frequent wars in Poland and Italy, and in 1022 he presided at the Council of Seligenstadt. He died in 1024, and was canonized by Pope Eugenius II. in 1152. With him ends the Saxon line of emperors.

Conrad II., surnamed the Salic, a Franconian nobleman and a descendant in the female line of Otto the Great, was chosen to succeed him. In 1033 he succeeded to the kingdom of Arles, which provoked a war of succession with Eudes, Count of Champagne. He also spent several years in Italian wars. He died in 1039. He was succeeded by his son Henry III., who as on former occasions had been chosen in his lifetime. He exercised

more despotic authority in Germany than any of his predecessors, setting aside the fundamental laws of the empire established by the diets (q.v.). He died in 1056, and was succeeded by his son Henry IV., born in 1050. His long reign was filled with disasters owing to the turbulence of his kingdom and his differences with the Pope, in which his diets frequently sided against him. He was repeatedly excommunicated by popes, and deposed them in his turn. In 1077 Rudolph of Suabia was elected as rival emperor by the party obedient to the Church, or politically opposed to the emperor. Rudolph defeated him several times, but was mortally wounded in battle in 1080. Hermann of Luxemburg, chosen to succeed Rudolph, made peace with Henry in 1088. Conrad, the emperor's eldest son, next revolted, and was crowned in 1093. Henry put him under the ban of the empire and had his second son Henry elected his successor at the diet of Aix-la-Chapelle in 1098; but Henry was also induced to revolt by the inveterate enemies provoked by the reforms of the emperor, who was deposed in 1105, and died in the following year unabsolved by the Church.

Henry V., who had dethroned his father at the instigation of the Pope, inherited notwithstanding the quarrel with the Church about investitures. He was also engaged in wars with Hungary, Bohemia, and Flanders, in which he was frequently unsuccessful. He was excommunicated by seven councils and his subjects were incited to revolt by the papal legate. At length in 1122 he settled the question of investitures with Pope Calixtus II. He died in 1125. On his death there was a contested election and a civil war between Lothaire, Duke of Saxony, and Conrad of Hohenstauffen, in which the former was successful. A contest was now begun between the Saxon and Hohenstauffen (Suabian) families, in which the celebrated party names Guelph and Ghibelline originated. On the death of Lothaire in 1138 Conrad III. (of Hohenstauffen) was chosen to succeed him. The most powerful of his vassals was Henry the Proud, Duke of Saxony and Bavaria. At the diet of 1138 Henry was summoned to resign one of his duchies on the plea that it was contrary to the fundamental laws of the empire for the same person to hold two. On his refusing he was deprived of both and put under the ban of the empire. In May 1147 Conrad set out on the second crusade, from which he returned in 1149. He died in 1152, and was succeeded by his nephew Frederick Barbarossa. Frederick reconciled himself with Henry the Lion, son of Henry the Proud. Conrad had already restored to him the duchy of Saxony, and Frederick gave him back Bavaria.

Frederick is celebrated for his wars, particularly for the numerous invasions of Italy, in which the greater part of his life was passed. He held numerous diets to procure means for his campaigns and regulate the affairs of the empire. In this reign municipalities were first established whence arose the free cities (q.v.) which form one of the most interesting chapters of German history. At the diet of Würzburg in 1180 he put Henry the Lion, who had proved ungrateful to himself and of whose tyranny there were many complaints, under the ban of the empire and deprived him of all his estates. In 1189 he set out for Palestine, and was drowned near Seleucia 10 June 1190. His son Henry VI. began his reign with a war in Southern Italy. He imprisoned Richard I. of England, 1192–4. Like his father he was excommunicated by the Pope. He conquered Sicily and was crowned king of it in 1194. He died in Messina in 1197. Philip, brother of Henry, and Otto IV. were elected by rival factions in 1198. Philip, who was successful, was assassinated in 1208. Otto IV., the son of Henry the Lion, was recognized by the Diet of Frankfort in 1208 as the successor of Philip. After superintending the execution of severe edicts against the brigands of Germany he passed into Italy in 1209 and occupied himself with the conquest of the kingdom of the Two Sicilies, of which Frederick, son of the Emperor Henry VI., had been acknowledged king till 1212, when the Pope having stirred up a party against him, he returned to that country, but was unable to make head against Frederick, who had been elected to replace him, and retired to his hereditary dominions, of which his rival could not deprive him. He died in 1218.

Frederick II., King of the Sicilies, was elected emperor in 1212. One of the most remarkable characters in the 13th century, his life was passed in contentions with the popes about the Crusades and matters connected with Italian politics. The Lombard league was renewed against him. He was repeatedly excommunicated, and though he went on a crusade failed in all his efforts to reconcile himself with the Church. He passed a severe law against heretics and to put an end to the Guelph and Ghibelline factions in Germany, he erected the duchy of Brunswick for the descendants of Otto (1235). The independence of the German princes was legally established in his reign. Two rival emperors were put up against him by the Church party — Henry, Landgrave of Thuringia, in 1246, and William, Count of Holland, in 1247. He died in 1250. Conrad IV., his son, was excommunicated like his father, and had to contend against William of Holland. He died in 1254. He was the last emperor of the house of Hohenstauffen, which became extinct on the death of his son. His successor, William of Holland, was slain in Friesland in 1256. Richard, Earl of Cornwall, and Alfonso X., King of Castile, were chosen emperors in 1257; but the internal divisions of Germany had already deprived the office of all authority, and neither of them had any power. Till 1273 the German empire had no real head.

Rudolph of Hapsburg, the founder of the Austrian house, was chosen emperor in that year, and applied himself vigorously to repress the disorders to which this state of anarchy had given rise. He destroyed the castles of more than 70 robber nobles and executed many of the criminals. He also contrived to enrich his own family by his victories over the King of Bohemia and the recovery of the duchy of Austria, with which he invested his son Albert. He died in 1291. Adolphus of Nassau, his successor, was deposed in 1298 by the Diet of Mentz, which alleged a heavy list of crimes against him. Albert I., son of Rodolph, was chosen emperor the same year. He is chiefly celebrated for his wars with the Swiss as Duke of Austria, which led to the independence of

Switzerland. He died 1 May 1308, and was succeeded by Henry VII., of Luxemburg, nearly the whole of whose reign was passed in Italy, where he died in 1313. He obtained the kingdom of Bohemia for his son. In 1314 a double election took place, Frederick, Duke of Austria, sometimes called Frederick III., was elected along with Louis of Bavaria, and after a civil war was acknowledged as joint emperor in 1325. He died in 1330. Louis V., who now became sole emperor, was engaged in constant quarrels with the popes. He died excommunicated and deposed in 1347. Charles IV., King of Bohemia, and grandson of the Emperor Henry VII., was elected on the deposition of Louis in 1346. He was chiefly occupied with the care of his hereditary dominions and was little respected in Germany. His reign is chiefly distinguished for the Golden Bull (1356) regulating the electorate, which is treated of elsewhere. Several rivals were opposed to him at the beginning of his reign. He died in 1378. Wenceslaus, his son, was deposed for his excesses first by the electors of the empire in 1400. Rupert, Count Palatine, elected 1400, possessed little authority. Sigismund, King of Hungary and Bohemia, son of Charles IV., was elected by a party in 1410, and unanimously in 1411. His reign is distinguished by the commencement of the Reformation in Bohemia, by the Council of Constance, the condemnation of Huss and Jerome, and the burning of the former in violation of the emperor's safe conduct. He died in 1437. Albert II. (V. of Austria), son-in-law of Sigismund, was elected in 1438, and died in the following year. He was succeeded by his second cousin Frederick, Duke of Styria and Carinthia, usually called Frederick III. His character was feeble and his authority small. The empire was disturbed with commotions which he hardly tried to suppress. He was engaged in war with his brother Albert for his hereditary estates, and with George Podiebrad and Matthias, Kings of Bohemia and Hungary, on which kingdoms he had claims. He was also involved in the disputes between France and Burgundy. Yet he has earned the epithet of Pacific. He originated the famous motto of the house of Austria — *a. e. i. o. u.* (*Austriæ est imperare orbi universo* — It is Austria's part to rule the whole world), and though unsuccessful in all his plans, he did something to justify it in marrying his son Maximilian to the heiress of Charles of Burgundy. In his reign Constantinople was taken by the Turks. He died in 1493, and was succeeded by his son Maximilian I. His marriage with Mary of Burgundy brought the Netherlands again into close relationship with the empire and revived claims on Burgundy which he was unable to maintain against the rising power of France. In 1496 his son Philip married Joanna, the daughter of Ferdinand and Isabella of Spain. The French monarchy, consolidated by Louis XI., had already entered on the sphere of European politics, and with the invasion of Italy by Charles VIII. in 1494 had begun that contest for supremacy with the rival power of Germany, which, whether in the form of a conflict between rival monarchies, or of a deadlier struggle between opposed nationalities, has continued to the present day. Maximilian invaded Burgundy in 1498, but was compelled to submit his claims to arbitration. With the support of the diet he also endeavored to revive the claims of the empire on Switzerland, and reduce it under the authority of the newly created Imperial Chamber. A bloody war ensued in 1499, in which he was defeated and compelled to make peace. He was constantly frustrated in his wars by want of means to keep his armies together. France, Spain, and Germany, after struggling and intriguing with alternate success for the supremacy in Italy, united in 1508 with the Pope in the celebrated league of Cambrai against Venice. Maximilian abandoned this league in 1511 to enter into another fomented by the Pope, and hence called the Holy league, with Spain and England against France. About the same time he made a curious attempt to get himself on the next vacancy elected pope. In 1516 he invaded Italy, but the insubordination of his troops for want of pay compelled him to make an ignominious flight. In 1518 the affairs of Luther were first brought before the Diet of Augsburg. Maximilian died in 1519. He was succeeded by his grandson, Charles V., who had inherited the crown of Spain through his mother, and thus united under his sway a great part of Europe with the rich possessions of Spain in the New World.

The reign of Charles, the most important in the German annals and the most brilliant in the 16th century, was divided among three great conflicts — the continued struggle between France and Germany; the conflict with the Turks, whose encroachments threatened the hereditary dominions of the house of Austria; and the kingdom of Hungary, which, together with Bohemia, fell after the death of Louis II. at the battle of Mohacz to the emperor's brother Ferdinand; and the conflict with the Reformation. In the first of these Charles enjoyed his most brilliant successes, particularly in the victory of Pavia (1525), which made Francis I. his prisoner; but Charles' seeming preponderance of power was very nearly balanced by the more central position of France and the more available character of her resources, and after all his successes he only succeeded in bequeathing to his son Philip of Spain an unfinished war, suspended by a truce which left France in possession of Savoy and the frontier fortresses of Metz, Toul, and Verdun. The material results of this struggle in the various treaties with France which resulted from it will be found in our history of that country, and its various incidents and episodes, the alliances of both kings with England, the defection of Bourbon, the emperor's quarrel with Clement VII., the sack of Rome, in the respective biographies. The war with the Turks became formidable, when, after his victory at Mohacz (1526), Solyman set up a king of Hungary and laid siege to Vienna (1529); and his repeated invasions of Hungary and alliances with France continued to harass the empire till the close of Charles' reign. This war also had its episodes in the naval expeditions of Doria and the emperor to Tunis (1535) and Algiers (1541).

But the most important feature of Charles' reign was the struggle with the Reformation (q.v.), and in it he can be credited with neither glory nor success. It cannot be disguised that his policy with the Reformers was tortuous.

When his foreign policy required it, and particularly when pressed by the Turks, he made concessions freely; but when, with the active assistance of the Reformers he had been relieved from this danger and had been left at liberty by the Peace of Crespy (1545) to attend to the internal affairs of the empire, he speedily withdrew his concessions. The league of Schmalkalden, with which the emperor had concluded the Peace of N iremberg in 1532, through the bad generalship and divided counsels which are inherent in such combinations, suffered a decisive defeat at Mühlberg in 1547; but Charles was not yet wholly master of the situation, and the famous Interim of the Diet of Augsburg in 1548 was the fruit of his victory. But this success was dearly purchased. Maurice, whom he had made Elector of Saxony, put himself at the head of a new league, which did not commit the faults of its predecessor, and extorted the treaty of Passau in 1552, by which the whole policy of the emperor's reign was overturned and the liberty of Protestant worship secured. In 1554 Charles negotiated the marriage of his son Philip with Mary of England. The treaty of Passau had provided for referring the religious disputes to a diet, and at the Diet of Augsburg in 1555 a religious peace was negotiated by Ferdinand, the emperor's brother. It contained two provisions, which ultimately aggravated existing differences and were a main cause in promoting the Thirty Years' War. The Lutherans were then the chief body of Reformers in Germany, but the Calvinists were rapidly increasing in numbers and influence. The toleration granted by the peace was limited to the followers of the confession of Augsburg. One of the great causes of difference between the Catholics and the Reformers was the great amount and peculiar tenure of ecclesiastical property to which we have already alluded. The secularization of this property was looked on as a profanation by the Catholics, while the Protestants could not be expected to see with complacency possessions which conferred political power and dignity to the extent of direct personal authority exclusively in the hands of their enemies. A large amount of ecclesiastical property had already been secularized through the conversion of its holders. This was in fact a powerful motive to conversion, as the Church did not give hereditary possession. The Catholics now succeeded in securing an article called the Ecclesiastical Reservation, by which any holder of an ecclesiastical benefice changing his religion should forfeit the benefice. This seemingly reasonable provision excited the strenuous opposition of the Protestants, and was only permitted to pass under protest. In 1556 Charles resigned the empire to his brother Ferdinand. The Netherlands and the Italian possessions, for which so much German blood had been spilt, had already been given with the kingdom of Spain to his son Philip. Charles retired to the monastery of St. Just in Estremadura, where he died in 1558.

The Pope refused to recognize the abdication of Charles and the accession of his successor, and declared the acts of the Diet of Frankfort (in 1558), which had acknowledged Ferdinand, null and void. Ferdinand in consequence assumed the title of emperor elect, and from this time coronation by the pope was no longer deemed necessary by the German emperors. Ferdinand observed the religious peace and was chiefly occupied with the affairs of his hereditary dominions. He succeeded in making Bohemia hereditary and in 1562 concluded a truce for eight years with the Turks. The Council of Trent was concluded in his reign. He died in 1564. Maximilian II., son of Ferdinand, was distinguished for the moderation of his policy in regard to religion. He extended toleration to his hereditary dominions. Maximilian was in 1566 engaged in a fresh war with the Turks in Hungary, during which Solyman died from fatigues incurred in the obscure fortress of Szigeth. Maximilian died in 1576, while he was preparing to assert his claim to the crown of Poland. His son, Rudolph II., who had been brought up in Madrid, was, in contrast to his father, a Catholic zealot, and soon rendered himself unpopular by his persecution of the Protestants and by his complete incapacity for government. The Archduke Ferdinand of Styria, and Maximilian, Duke of Bavaria, also distinguished themselves by their zeal for the Catholic religion. The latter procured a decree of the Aulic Council putting the free imperial city of Donauwörth under the ban of the empire, and entrusting him with its execution. The proceedings which followed, known as "the troubles of Donauwörth," occasioned the formation of the Protestant Union 4 May 1608. This was followed by a counter-association on the part of the Catholics (July 1609), called the Holy league. A war with the Turks was favorably concluded by the Peace of Sitvatorok in 1607. In 1609 Rudolph was compelled by his Bohemian subjects to sign a *Majestätsbrief* granting complete religious liberty, which was one of the proximate causes of the Thirty Years' War. He was forced in 1608 to resign to his brother Matthias the crown of Hungary, and in 1611 that of Bohemia. He died in 1612.

Matthias, who succeeded him as emperor, was not a much better ruler than his brother, and Germany under his reign continued rapidly to become more disorganized. With the consent of his brothers he adopted his cousin, Ferdinand of Styria, as his successor, and resigned to him the crowns of Hungary and Bohemia during his lifetime. He died in 1619. Ferdinand II. was more capable than his two immediate predecessors; but chronic religious strife made his reign calamitous. His Bohemian subjects were already in open revolt and offered the crown of Bohemia to the Elector Palatine Frederick V., who, though the Protestant Union was divided in opinion on the subject, decided to accept it. Frederick was defeated in the battle of Prague (8 Nov. 1620), put under the ban of the empire, and deprived of his estates, which, together with the electorate, were given to the Duke of Bavaria in 1623. These events form the commencement of the Thirty Years' War, the details of which will be found in a separate article. The invasion of Germany by Christian IV. of Denmark in 1625, the Peace of Lübeck (27 May 1629), the invasion of Gustavus Adolphus (1630), the battles of Leipsic in 1631, of the Lech and Lützen in 1632, of Nördingen in 1634, the war with France in 1635, belong to the history of the Thirty Years' War, and the policy of Richelieu.

The troubles of this period were increased by the edict of restitution passed in 1629, which revived the Catholic claims on all Church property secularized since the Peace of Passau in 1629. Ferdinand died in 1637. His son, Ferdinand III., had gained a military reputation by the battle of Nördlingen, but he did not put it to the proof by taking the command of his armies. Baner, Frederick of Saxe-Weimar, Torstenson, Turenne, and the great Condé gained repeated victories over his troops. He was at length induced to enter into negotiations. The war, through complication with the affairs of Spain and the Netherlands, had gradually extended throughout Europe.

A congress of nations was opened in the towns of Münster and Osnabrück, the Catholic powers being represented at the former and the Protestant at the latter (1643); and after some years of fighting and negotiation the Thirty Years' War was concluded by the Peace of Westphalia (24 Oct. 1648), in which the policy of France and Sweden was triumphant. The principal conditions which concerned Germany were a general amnesty and restoration of rights; the Upper Palatinate was retained by Bavaria, the lower, with a new electorate, was restored to Charles Louis, son of Frederick V.; the diets of the empire were to have the sole power of making and interpreting the laws, of levying taxes, raising troops, making treaties, and declaring war; the imperial chamber and the aulic council were to be reformed so as to give greater power to the Protestants; and the right of the princes and states to make war and alliances among themselves or with foreigners was recognized. Thus the policy of the Diets of Nuremberg, Worms, and Frankfort was defeated, and the consolidation of the German empire frustrated, the great aim of Richelieu. The bishoprics of Metz, Toul, and Verdun, with Breisach, Upper and Lower Alsace and 10 imperial cities, were ceded to France; the independence of Switzerland was acknowledged, and the claims of the empire on the Netherlands abandoned, and some cessions of territory were made to Sweden.

After the Peace of Westphalia Ferdinand continued to afford the Spaniards material assistance in their war with France. Two leagues formed in Germany after the Peace of Westphalia, called respectively the Catholic and the Protestant league, enabled France to maintain its influence in the affairs of Germany, and several of the German princes entered into the French alliance. The Peace of Westphalia was confirmed by the Diet of Ratisbon in 1654. The emperor died in 1657. His son, Leopold I., was already King of Hungary and Bohemia (1655–6). He was elected emperor in 1658, although the French ambassadors who were admitted to the electoral diet made an effort to divert the imperial crown from the house of Austria. They succeeded in imposing as a condition of his capitulation that he should not assist the enemies of France in the war then in progress. Further to secure the neutrality of Germany in the war with Spain, Mazarin also succeeded by his influence with the ecclesiastical electors in combining the two leagues, Catholic and Protestant, into one called the Rhenish league, under the protection of France, for the maintenance of the Peace of Westphalia. This league was tacitly recognized by the emperor, who received a contingent of troops from Louis XIV., as a member of it, in the Turkish campaign in 1664. The treaty of Oliva in 1660 put an end to the war, in which Sweden, Poland, Denmark, and the electorate of Brandenburg were more concerned than the empire. In 1668 Leopold entered into the first of the series of treaties with France in regard to the claims of both monarchs to the Spanish succession, which ended in the establishment of the Bourbons on the throne of Spain. The success of Louis XIV. in his invasion of Holland led to a coalition against him, in which the emperor after temporizing for some time joined (30 Aug. 1673). The war was continued for some years and terminated by the Peace of Nimeguen, acceded to by the emperor on 5 Feb. 1679. A formidable war with the Turks broke out in 1663. Vienna, besieged in 1683, was saved by John Sobieski, King of Poland. In 1684 the Holy league was formed against the Turks with the King of Poland and the republic of Venice, and the war was continued till 1699, and concluded by the Peace of Carlowitz, when the Turks abandoned their claims in Hungary, Transylvania, and Slavonia.

The intolerance of the Austrian government and the persecutions of the Protestants had caused various insurrections in Hungary, and led the Protestants even to favor the Turks, who did not molest them. In 1687 Leopold proposed to the states of Hungary to incorporate his conquests from the Turks in that kingdom, and grant religious liberty, if they would abandon their constitution and make the kingdom hereditary. This being acceded to, his son Joseph was crowned King of Hungary. The emperor, with other German princes, joined in the league of Augsburg (9 July 1686) against Louis XIV. A protracted war, distinguished by the devastation of the palatinate, was concluded by the Peace of Ryswick, acceded to by the emperor 30 Oct. 1697. In 1692 the emperor erected Hanover into an electorate on terms which offended some of the German princes, and in 1700 he permitted the Elector of Brandenburg, Frederick III., to take the title of King of Prussia. The war of the Spanish Succession, in which Great Britain, Holland, and the empire were leagued against France was begun in 1702. The Emperor Leopold died in 1705. He was succeeded by his son, Joseph I. At the commencement of his reign insurrections occurred in Hungary and Bavaria; the Electors of Cologne and Bavaria were put under the ban of the empire; the estates of the latter were divided, and the Upper Palatinate was restored to the elector palatine. The success of the imperial arms enabled the emperor to revive the claims of his house upon Italy. Joseph died in 1711. He was succeeded by his brother, Charles VI., the claimant of the Spanish crown. The alliance against France was dissolved by the Peace of Utrecht in 1713, to which the emperor refused to accede, and was left alone against France.

After a brief campaign between Prince Eugene and Villars he acceded to the Treaty of Rastadt, negotiated between these commanders 7 March 1714, on his own behalf, and on behalf of the empire at Baden 7 Sept. 1714. The Spanish Netherlands, and Naples, Milan, Sar-

dinia, and other Italian conquests, were left to the emperor. By the Barrier Treaty (15 Nov. 1715) between the emperor and the States-General of the United Provinces, an arrangement was made for the joint garrisoning of the fortresses of Namur, Tournai, Ypres, etc. A short war against the Turks, conducted by Prince Eugene, ended, by the Peace of Passarowitz (21 July 1718), in further acquisitions to the hereditary possessions of Austria. The quadruple alliance formed by England France, Austria, and the United Provinces (1718–19) against Spain provided for mutual renunciations on the part of Philip V. and the emperor of their respective claims on Spain and the Netherlands, and a readjustment of possessions in Italy, where a war had already broken out between them. Spain acceded to the alliance after a brief resistance in 1720. Its most important consequence was the erection of the kingdom of Sardinia under Victor Amadeus II. of Savoy. The emperor having no male heirs had promulgated in 1713 the pragmatic sanction regulating the succession to his hereditary dominions in favor of his daughters in preference to those of his brother, Joseph I. This was acceded to by the states of Austria in 1719, and afterward by the other hereditary states, and having been subsequently guaranteed by England, Holland, Spain and France, eventually led to the war of the Austrian Succession.

A disputed succession to Poland led to a war between France and Austria in 1733, in which the French attacked the Italian provinces of the emperor and invaded Germany. Peace was concluded at Vienna 18 Nov. 1738, by which the emperor lost Naples and Sicily and part of his possessions in Northern Italy and acquired the duchy of Parma, while the Duke of Lorraine, who was to marry his daughter, Maria Theresa, received the arch-duchy of Tuscany in exchange for his own duchy, and France guaranteed the pragmatic sanction. In 1737 the emperor joined Russia in a war with the Turks. Peace was concluded in 1739 on unfavorable terms, Austria surrendering Belgrade and agreeing to evacuate Servia and Wallachia. The emperor died in 1740. Charles Albert, Elector of Bavaria, son-in-law of Leopold I., was chosen emperor in 1742, and crowned with the title of Charles VII. He laid claim to the hereditary possessions of the house of Austria, and had already occupied Bohemia and been crowned king of that kingdom in 1741. He had also entered into an alliance with France, Spain, Prussia, etc. (treaty of Nymphenburg), against the claims of Maria Theresa, who was supported by England, Holland, Poland, etc., called the Alliance of Hanover. So began the war of the Austrian Succession (see AUSTRIA; SUCCESSION WARS). Charles VII. was driven from Bohemia, and lost his hereditary states of Bavaria, which Marshal Seckendorf recovered for him. He died in Munich in January 1745. Francis I., Grand-Duke of Tuscany, the husband of Maria Theresa, was elected emperor at Frankfort on 13 September, and thus the house of Hapsburg-Lorraine, which had succeeded to the hereditary possessions of Austria, was recognized as the head of the empire. The war of succession was concluded by the Treaty of Aix-la-Chapelle (18 Oct. 1748), to which the emperor was not a party, though the empire lost by it some of its Italian fiefs. The chief result of the war was the annexation of Silesia to Prussia.

This peace was followed after a brief interval by the Seven Years' War (1756–63), excited by the desire of Maria Theresa to recover Silesia, in which war Austria, Russia, and France, with Saxony and other powers, combined together against Prussia. This war was concluded by the Peace of Hubertsburg (15 Feb. 1763), in which the empire was included. Prussia retained her acquisitions and Frederick II. agreed to support the election of the eldest son of Maria Theresa as King of the Romans. The death (in 1765) of Francis I., who had exercised little influence on political events, led to the succession of this prince as Joseph II. He was of an active and reforming disposition. He joined with Russia and Prussia in the first partition of Poland (1772). The Bavarian line having become extinct, the elector palatine succeeded to it after a war terminated by the Peace of Tesche (13 May 1779). Maria Theresa died in 1780, and Joseph succeeded to the Austrian dominions, of which he had been coregent since 1765. In 1781 he put an end to the Barrier treaty, and razed the fortresses which the Dutch were entitled by it to occupy. In the same year he issued a decree abolishing monastic orders and making other ecclesiastical reforms, and also an edict of religious toleration.

These reforms, which procured him the title of the philosophic emperor, caused much discontent to his Catholic subjects and, together with other grievances, caused a revolt in the Netherlands (see BELGIUM), which was not suppressed till after his death, which occurred in February 1790. He was succeeded by his brother Leopold. His domestic policy was reactionary and he joined with Frederick William II. of Prussia in the celebrated Declaration of Pilnitz (27 Aug. 1791) against the promoters of the French Revolution. He died 1 March 1792, and was succeeded by his son, Francis II. Francis confirmed the alliance of his father with Prussia, and was immediately involved in war with France. He joined in 1793 in the second partition of Poland. He took the command of his army against the French in 1794, concluded the peace of Campo Formio with Bonaparte (17 Oct. 1797); joined the second coalition against France in 1799 and concluded the treaty of Lunéville (3 Feb. 1801); joined the third coalition in 1805, and concluded the Treaty of Presburg (26 Dec. 1805). The results of these treaties may be found in our history of France. In 1804 Francis took the title of hereditary Emperor of Austria, and after the Peace of Presburg, the German empire having virtually dissolved by the Confederation of the Rhine, he renounced on 6 Aug. 1806 the title of its head. From this period till 1815 there is no united history of Germany.

The states of Germany were again united by the Treaty of Vienna (1815), in a confederation called the German Confederation (*der Deutsche Bund*); its proceedings, however, possessed for a time very little interest or importance. In 1818 a general commercial league, called the Zollverein, was projected by Prussia and was gradually joined by most of the German states except Austria. Germany had dur-

ing the French revolution imbibed liberal ideas which caused frequent troubles in the different states and more general outbreaks in 1830 and 1848. In the latter year the confederation underwent a revolution, and a constituent assembly was substituted for the diet. The diet was re-established in 1851. A reform of the confederation proposed by Austria in 1863 and accepted by the diet was rejected by Prussia. In 1866 the majority of the diet supported Austria in her dispute with Prussia respecting the disposal of the duchies of Schleswig and Holstein which had been jointly occupied under the authority of the confederation, whereupon Prussia withdrew from the confederation and declared it dissolved. The Seven Weeks' War between Austria and Prussia ended in the defeat of the former, the loss of her Italian possessions, and her exclusion from the German Confederation which was reformed by Prussia under the title of the North German Confederation. Peace was signed at Prague between Austria and Prussia on 23 Aug. 1866. Secret treaties of alliance had previously been entered into between Prussia and Würtemberg (13 August), Baden (18 August), and Bavaria (22 August). These were made public on 23 March 1867. The next great event was the war with France, which arose out of an offer of the crown of Spain to a Prussian prince (see FRANCO-GERMAN WAR), and resulted in the triumph of the German arms. In this great struggle the South German states, as well as the North German, supported Prussia. When the result of the war was no longer doubtful, the King of Prussia was invited to assume the title of German emperor, and he was accordingly proclaimed at Versailles on 18 Jan. 1871. The parliament of the new German empire met at Berlin on 21 March, and the constitution was adopted. The Emperor William I. died on 9 March 1888, and was succeeded by his son Frederick, who died on 15 June of the same year. Frederick's elder surviving son then ascended the imperial throne as William II., and has shown himself to be a monarch with a mind and will of his own, and a man of striking and somewhat peculiar personality.

The consolidation of the German empire was largely the work of Prince Bismarck, who became the first imperial chancellor. He successfully sought to secure Germany from attack, so as to enable her to develop her industries in peace, partly by the maintenance of a powerful, well-trained army, and partly by alliances with other powers. In 1879 he formed an alliance with Austria, and three years later with Italy. This Triple Alliance, as it is called, has been renewed in several subsequent years. During the earlier years of the reconstituted empire he was engaged, with the support of the powerful National Liberal party, in a contest with the papacy regarding the relations between the imperial government and the Roman Catholic religious societies of Germany. The Jesuits and similar orders were expelled in 1872, and a law was passed in 1874 making marriage a civil contract; but in 1880 and the years immediately following he found it expedient to open negotiations with papal representatives. Ultimately he admitted defeat by practically repealing the "Falk laws," as the anti-papal legislation was called after a Prussian minister of worship, and the last remnant of anti-Catholic legislation was repealed in 1904. It was Bismarck who in 1884 inaugurated German colonial development by declaring a protectorate over territories in Southwest Africa. (See COLONIES.) In his campaign against social democracy, which has become an important factor in German politics, Bismarck did not rely exclusively on force and repression. He sought to destroy the social discontent in which much of the strength of Socialism lay by passing measures intended to improve the condition of the working classes. In this respect his policy has also been maintained to the present time. See GERMANY, MODERN.

Germany, Modern. *Area and Population.*— The German Empire attained its existing territorial limits as well as its present political organization in 1871 (see GERMANY, HISTORY OF). The only territory which has been added since that time to Germany proper is the little island of Helgoland in the North Sea ceded by Great Britain in 1890. (For Germany's dependencies, see below.) Bounded on the north by the North Sea, Danish Jutland and the Baltic Sea; on the east by Russia and Austria; on the south by Austria and Switzerland; on the west by France, Belgium, Luxemburg and the Netherlands, Germany has a frontier of 4,769 miles, of which nearly one third is sea coast. Its area (exclusive of territorial waters in the North and Baltic seas and in Lake Constance) is 208,788 square miles.

The population of Germany in 1900 was 56,367,178. The increase of population from 1890 to 1895 was nearly three millions; from 1895 to 1900, over four millions. The excess of births over deaths in 1902 was 902,243. German emigration over sea (chiefly to the United States), which during the 19th century amounted to 6,500,000,— which in 1853 was 318,000 and in 1881 was 221,000,— has gradually decreased, in consequence of Germany's industrial development, until from 1897 to 1901, inclusive, it averaged only 23,000. In 1902 and 1903, in consequence of industrial depression, the numbers increased again, but in 1903 there were only 36,310 emigrants, of whom 33,649 went to the United States.

The average number of inhabitants to the square mile, which in 1871 was 197, had increased in 1900 to nearly 270. Apart from the city states (Hamburg, Lübeck and Bremen) the most densely populated of the German states is the kingdom of Saxony, which in 1900 had 728 inhabitants to the square mile.

The states of which the empire is composed, with their respective areas and population, are as follows:

States	Square Miles	Dec. 1, 1900 Population,
Prussia	134,621	34,472,509
Bavaria	29,294	6,176,057
Saxony	5,789	4,202,216
Wurtemberg	7,535	2,169,480
Baden	5,823	1,867,944
Hesse	2,966	1,119,893
Mecklenburg-Schwerin	5,069	607,770
Mecklenburg-Strelitz	1,131	102,602
Saxe-Weimar	1,397	362,873
Oldenburg	2,482	399,180
Brunswick	1,418	464,333
Saxe-Meiningen	953	250,731
Saxe-Altenburg	511	194,914
Saxe-Coburg	763	229,550
Anhalt	888	316,085
Schwarzburg-Sondershausen	333	80,898
Schwarzburg-Rudolstadt	363	93,059
Waldeck	433	57,918
Reuss-Greiz	122	68,396
Reuss-Schleiz	319	139,210
Schaumburg-Lippe	131	43,132
Lippe	469	138,952
Lübeck	115	96,775
Bremen	99	224,882
Hamburg	160	768,349
Alsace-Lorraine (territory)	5,604	1,719,470
Totals	208,788	56,367,178

The movement from country to city, noticeable in all modern industrial states, has been especially marked in Germany, and the increase of its urban population had been phenomenally rapid. In 1850, in the states included in the present German empire, 65 per cent of the population were living by agriculture and only 20 per cent by manufactures. In 1882 the agricultural population of the empire still exceeded the industrial by 3,000,000, but in 1895 the industrial population exceeded the agricultural by more than 300,000. During the same period the number of persons living by trade and commerce increased by 1,500,000. In 1895 a little less than 35 per cent of the population was living by agriculture; a little more than 35.5 per cent by manufactures; 11.5 per cent by commerce. Those engaged in mining, 3.6 per cent, were not included in the above categories. In 1871 the largest city in the empire, Berlin, had 826,341 inhabitants; in 1900 it had 1,888,848. During the same period, Hamburg, the second city, increased from 239,107 to 705,738. In 1871 there was but one other city, Breslau, with more than 200,000 inhabitants, and there were but five having between 100,000 and 200,000. In 1900 Breslau had more than doubled its population, but Munich, Dresden and Leipsic had outstripped it, trebling or quadrupling theirs, and other cities had grown proportionately, so that there were 15 cities with more than 200,000 inhabitants each, as follows:

	Population, Dec. 1, 1900
Berlin	1,888,848
Hamburg	705,738
Munich	499,959
Dresden	480,658
Leipsic	456,124
Breslau	422,709
Cologne	372,529
Frankfort on the Main	288,989
Nuremburg	261,081
Hanover	235,649
Magdeburg	229,667
Chemnitz	214,030
Dusseldorf	213,711
Stettin	210,702

There were 20 other cities with more than 100,000 inhabitants; 41 with between 50,000 and 100,000; 48 with between 30,000 and 50,000; and 85 with between 20,000 and 30,000.

Language.—Placed as it is in central Europe, without natural boundaries to separate it from the surrounding nationalities, the German people has never possessed a well-rounded or perfectly defined ethnographic territory; and even if states could be built on purely theoretical lines it would be difficult to construct a Germany that should include all areas in which the German element predominates and exclude all others. In the new Germany, however, such a result is at least approximately attained. The empire includes more than four fifths of the German-speaking inhabitants of Europe, and the census of 1900 showed that of the total population (including 778,698 resident aliens), 92 per cent had no mother-tongue but German. Those speaking Polish only, or German and Polish, constituted 6 per cent of the total population; the French element six tenths of one per cent. The remainder, 1.4 per cent, was composed chiefly of Danes, Czechs, Lithuanians, Wends, Netherlanders and Italians.

Religion.—In the census of 1900, 35,231,104 men, women and children (62.5 per cent of the entire population) are counted as Protestants; 20,321,441 (36.1 per cent) as Roman Catholics; 586,833 (a trifle over one per cent) as Israelites. Of the remainder 210,265 are described as belonging to other Christian sects, and 17,535 as confessing other religions or avowing none. Western Germany, which until the beginning of the 19th century was largely ruled by Catholic prelates, and southern Germany, where the Austrian influence was formerly supreme and the counter-reformation of the 16th century swept everything before it, are predominantly Catholic; middle Germany and northern Germany are almost wholly Protestant; while in the eastern provinces, where nearly all the Germans are Protestants and all the Poles are Catholics, the confessions are approximately balanced. In the German states, as in other European countries, the maintenance of religion and of public worship is regarded as a proper function of government, and the Catholic and Protestant churches and clergy are paid by the state. Over the Protestant establishment the control of the state is very extensive. The effort of the Prussian government to exercise somewhat similar control over the Catholic church led to the so-called "culture-conflict" of the seventies, in which, on the whole, that church successfully asserted its independence.

Education.—In no country is education better organized through all its stages, from the common school to the university, than in modern Germany. Education, like religion, is a matter with which the empire has nothing to do: it appertains to the single states, and is regularly placed under the same department, namely, the ministry of worship (*Cultus*) and education. In spite of the lack of central control, fairly uniform conditions exist in the different states. In 1898 Germany had (approximately) 59,300 common schools (*Volksschulen*), with 137,000 teachers and 8,660,000 pupils. There were also 98 schools for the deaf and dumb and 32 for the blind. There were 457 normal schools or teachers' seminaries for the education of com-

mon-school teachers, 222 supported by the states, the remainder established by the municipalities or by private enterprise. Above the common school, in the German system, stand schools with a seven-year curriculum, corresponding roughly to the American high schools or "fitting schools" and colleges. Those which give a classical course are known as *Gymnasien;* those which give a liberal scientific training as *Realschulen.* There are also schools of an intermediate type described as *Realgymnasien.* Of these three types there were in 1898, 1,108 schools with 16,380 teachers and 288,000 pupils. These furnish the necessary preparation for the universities and for the higher technological institutions. For young men who cannot look forward to a university education there has been in the different states an increasing, although unequal development of a less ambitious secondary education in the so-called *Mittel-*, or *Bürger-,* or *Fortbildungsschulen.* These are largely commercial or industrial or agricultural schools. For young women, who are not admitted to the *Gymnasien,* there has been a rapidly increasing development of *höhere Mädchenschulen.* These are for the most part private schools, although many are maintained by the cities and a few by the states.

The universities, which form the crown and glory of the German educational system, are all state institutions. They furnish professional training to clergymen, physicians, lawyers, teachers of the higher grades, and state officials, and in addition they nurture in a few chosen students the spirit of research. There are 22 German universities, half of them in Prussia. The oldest is that of Heidelberg (1386); the newest that of Strassburg (1872). Berlin, Munich, Leipsic, and Bonn have of late years attracted the largest number of students, the attendance varying from six or seven thousand regularly matriculated students at Berlin to between two and three thousand at Bonn. Very many students divide their period of academic study between two or three universities. Until recently, women were not admitted to the universities, nor are they now admitted to all.

For historical rather than logical reasons, the universities have not generally attempted to give intending engineers, chemists, etc., a strictly professional training. The university professors of the natural sciences were more interested in these sciences themselves than in their application. The gap has been filled by the development of technological institutions of the highest grade. Of these there are three in Prussia and six in other states. In 1898 these institutions had 14,614 regular students, Berlin leading the rest with 4,343. Of late years commercial schools of a very high grade, practically on a level with the technological institutions, have been established in a few German cities.

Attendance at the common schools is compulsory. In 1900 the proportion of illiterates among the army recruits was less than half of one per cent in the most backward district. East Prussia, and less than one fourteenth of one per cent in the empire. In Brandenburg, among 17,584 recruits, and in Würtemberg, among 11,776 recruits, there were no illiterates.

Industry and Commerce.—As has been noted in the statistics of population, Germany has been transformed, since the middle of the 19th century, from an agricultural nation into an industrial and commercial power of the first rank. The change began in 1834, when the customs union of the German states established internal free trade with a moderate degree of protection against the rest of the world. Since the establishment of the present empire, however, Germany's industrial and commercial development has been phenomenally rapid. As regards food, it is no longer self-supporting: in 1903 the value of its cereal imports exceeded that of its cereal exports by 567,800,000 marks. It imports twice as much wine as it exports and more than twice as much tobacco. Its only important agricultural export of late years has been beet sugar; and this may perhaps be justly regarded as an industrial rather than an agricultural product. Germany's chief exports are coal, iron and steel, and machinery; cotton, linen and silk goods and chemicals. In drugs and other chemical products it almost controls the markets of the world. In the amount of its exports, as in the total of imports and exports together, it has long passed beyond France and is second, in Europe, to Great Britain only. In 1899 the total value of its imports and exports (precious metals excluded) was 9,690,000,000 marks. In 1903 the total value had risen to 11,017,000,000 marks. The German merchant marine also has grown very rapidly in the last 30 years. In 1871 the total tonnage of its sea-going vessels was 982,355, and of this only 81,994 was steam tonnage. In 1903 the total tonnage was 2,203,804, and of this 1,622,439 was steam tonnage. Germany's success in the world market is due in large measure to the co-operation of German science with German industry, and to the establishment of technical and commercial schools of a high type.

Social Conditions.— Before the law all Germans are equal, but socially there are marked class distinctions which are not without influence, notably in the matter of appointment to office. Nobles are still preferred to commoners in the army, in diplomacy, and, to a less extent, in other branches of governmental service. The middle class, the bourgeoisie, has made the greatest advance in the last hundred years. It holds nearly all the new wealth that is now accumulating with unprecedented rapidity. Little of this finds its way into the hands of the nobles, except by marriage.

While the condition of the peasants has improved, the artisan class has suffered, as in other countries, from the development of the factory system. Wages have risen faster than the necessaries of life, and the cheapening of products has brought many things within the reach of the laborer which at the beginning of the century would have seemed unattainable luxuries. But his work is harder and more monotonous and employment is more uncertain. The evolution from status to contract has made him more independent, but it has destroyed the ties which formerly subsisted between master and man, binding them to each other in relations that were not exclusively economic, but also human. The discontent of this class has found expression in the Social Democratic party. From 1878 to 1890 a fruitless attempt was made to suppress this party by special laws. At the same time serious efforts were made to improve by legislation the position of the workingmen — efforts which culminated in a remarkable scheme of state-assisted compulsory in-

surance against accident, disease, and old age. Whatever the ultimate results of these laws may be they have as yet done nothing to check the growth of the Social Democratic party. See *Political Parties*.

Political Organization.— From 1815 to 1866, Germany was organized as a loose confederation of 38 sovereign states, namely: Austria, Prussia, and 4 small kingdoms; 28 grand-duchies, duchies, and principalities, and 4 free cities. This confederation was dissolved in 1866, as a result of the conflict between Prussia and Austria; in 1867 northern Germany was reorganized into a strong federal union, with the king of Prussia as president; in 1871, during the Franco-German war, Bavaria, Baden, Würtemberg, and Hesse united with the northern states to form the German empire, and the title of its president was changed to German emperor. Of the 38 states which were members of the confederation of 1815, 3, namely: Austria, Lichtenstein, and Luxemburg, are not included in the empire; 10 others, whose territories are included in the empire, have ceased to exist as separate states; so that the empire is composed of but 25 states: 4 kingdoms, 18 grand-duchies, duchies, and principalities, and 3 free cities. Alsace-Lorraine, ceded by France in 1871, is organized not as a state but as an imperial territory (*Reichsland*). The constitution of the empire, which is simply a revision of the North German federal constitution of 1867, vests the sovereignty of the empire in the allied princes and cities, represented by appointed plenipotentiaries in the Federal Council (*Bundesrath*). In this council Prussia has 17 votes, Bavaria 6, Saxony and Würtemberg each 4, and the other states, in proportion to dignity and size, from 3 votes to 1. In this distribution of votes the federal principle is asserted, and by it the rights of the smaller states are safeguarded. Not only has Prussia, with three fifths of the total population, no majority in the Council, but it would be possible for a combination of small states, including less than one fifth of the total population, to outvote Prussia and the remaining states. So long, however, as Prussia refrains from threatening the rights of the little states no such combination can be made, and the emperors and their chancellors have thus far worked in substantial harmony with the allied sovereigns and their representatives. The German people are directly represented in the Imperial Diet. See *Imperial Legislation*.

The Imperial Administration.—The general executive power of the empire is vested in the Federal Council; but certain very important special powers, including the conduct of foreign affairs, and the command of the army and navy, are entrusted to the emperor. Internal administration is for the most part left to the single states; and such administrative powers as are conferred upon the empire are largely exercised through state officials under federal supervision and control. The central administration of the empire is conducted by a chancellor, appointed by the emperor. Under the chancellor are several secretaries of state, heads respectively of the departments of foreign affairs, of the interior, of justice, of the treasury, etc. With military affairs the chancellor has nothing to do: so far as the military administration pertains to the empire, it is under the immediate control of the emperor himself. The fact that the emperor, as king of Prussia, rules immediately over three fifths of the German people, of course greatly modifies his position and increases his power.

State and Local Government.—In the management of their own affairs the states are practically independent of the empire. Twenty-two of the states are monarchies; three, the free cities, are republics. In all the monarchic states except the two Mecklenburgs there is now constitutional government of a modern type. The Mecklenburgs have a mediæval diet of great landholders and city magistrates. Of the free cities, Lübeck has a government of a restricted democratic type; Hamburg and Bremen have governments of a mixed type.

In the larger states, notably in Prussia, the localities, especially the municipalities, enjoy a very considerable degree of self-government. Municipal self-government in Prussia dates from the reforms of Stein, at the beginning of the 19th century. An analogous system for the rural districts was established by Bismarck. The leading features of the Prussian system are compulsory and unpaid service on the part of those called to local offices, and the control of the local administration by elected councils. The Prussian system has been imitated in many of the other states.

Imperial and State Finances.—The empire has the power of levying import duties and excises. Its revenues are derived chiefly from import duties; from excises on brandy, wine and beer, sugar, salt and tobacco; and from stamp duties. It also draws a profit from the administration of the postal and telegraph system and from the management of the imperial railways. If further revenues are required, these are provided by contributions from the single states in proportion to their population. The debt of the empire, at the close of the year 1902, amounted to 3,173,500,000 marks.

The revenues of Prussia and of the other states are chiefly derived from direct taxes, especially income taxes and succession duties; from the administration of the state domains, forests and mines, and from the management of state railways. State lotteries are still in existence.

Taxes on real property are levied chiefly for the support of local government.

Imperial Legislation.—The legislative power of the empire extends over all matters of common or national concern, including the entire field of civil and criminal law. This power is exercised by the Federal Council and the Imperial Diet (*Reichstag*). This latter body represents not the states but the German people, and its members are directly elected by them, every male German 25 years old, not convicted of crime nor dependent upon public support, having the right to vote. A Diet may be dissolved and new elections ordered, with the consent of the Federal Council, at any time; but except in case of such dissolution the term of the Diet is five years.

The assent of the Diet is required not only for new legislation but for the imposition of taxes and for all appropriations. The strength and organization of the army is commonly determined for a period of years in advance: but the budget of imperial receipts and expenditures is submitted annually for approval.

The imperial constitution is amended by the

ordinary process of legislation, that is, by concurrent action of the Diet and the Federal Council, the only difference being that a bill amending the constitution may be defeated by 14 negative votes in the latter body. As Prussia has 17 votes, and these are cast in accordance with the instructions of the king, the emperor as king of Prussia has practically the power of vetoing constitutional amendments.

Political Parties.—German political parties are numerous, and these separate easily into more or less independent "fractions." At no time, since the empire was formed, has a single party had a majority of votes in the Diet. The principal parties are the Conservatives, always divided into two and sometimes into three fractions; the Liberals, with even more fractions; the "Centre" or Catholic party, which for many years has been the strongest single group; and the Social Democrats, who at present (1905) constitute the second strongest group. This party, which in 1867 had but two representatives in the North German Diet, elected 24 members of the Imperial Diet in 1884, 57 in 1898, and in 1903 it cast more than 3,000,000 votes and elected 77 members. It appears, however, that as this party grows stronger, it is becoming less uncompromisingly intolerant of the capitalistic régime, and more inclined to aid in bettering the position of its constituents, the workingmen, within the existing social order.

Law and its Administration.—Before the formation of the North German Federation in 1867 Germany was governed by a multiplicity of laws. In civil matters, the Roman law was in theory common law; but in three fourths of Germany the Roman law had been superseded by local codes. There were different laws not only in each state but in many instances in different parts of the same state. A first step toward the unification of the law was taken in the confederate period: a commercial code drafted by commissioners of the several states was put in force by the nearly unanimous action of the state legislatures. The North German Federation adopted a common criminal code; the legislation of the new empire has produced national codes of civil and criminal procedure and finally, in 1897, a general civil code.

Justice is administered, primarily, by state courts; but the organization, competence and procedure of these courts are determined by imperial laws. The lowest courts, which deal with petty civil and police cases, are described as *Amtsgerichte* and are composed of a single judge and two lay assessors (*Schöffen*). The ordinary court of first instance is the *Landgericht* (or *Stadtgericht*), in which civil cases are determined by the judges alone. In criminal cases a jury is impanelled, and the court becomes a *Schwurgericht.* There are also special commercial courts (*Handelsgerichte*) in which cases are decided by professional judges with expert lay assessors. From the ordinary courts and commercial courts appeals run to superior courts (*Oberlandesgerichte*). The majority of the German states are too small to constitute separate appellate districts. In some cases several of them are grouped into a single appellate district; in other cases they are placed under the appellate jurisdiction of the *Oberlandesgericht* of a larger neighboring state. At the apex of the judicial system stands the imperial court (*Reichsgericht*), to which appeals run from all the state courts on questions of law. This court has also original jurisdiction in a limited range of cases. The imperial court can pronounce state laws void if they conflict with the provisions of the imperial constitution; and it can refuse to apply ordinances proceeding from imperial or state authorities if these trench on the field of legislation; but they cannot pronounce an imperial law invalid as being contrary to the imperial constitution, because the Imperial Diet and the Federal Council have power to amend the constitution, and the courts cannot go behind the declaration of the Federal Council that the law was passed and inquire by what majority it was passed.

The German Army.—In time of peace the armed forces of Prussia, of Bavaria and of the other states are, in a sense, separate bodies, each under command of the sovereign of the state. The duty of every male German citizen to serve in the army is, however, established by the imperial constitution; the strength and general organization of the army are determined, from time to time, by imperial law; the emperor is commander-in-chief of all the German forces, appoints or approves appointments to the higher military positions, and possesses general powers of inspection and control over the non-Prussian as well as the Prussian forces. Moreover, by special treaty arrangements, the contingents of nearly all the smaller states have been fitted into the Prussian organization.

The general military system is that which was devised by Prussia in the early part of the 19th century and which has since been imitated by the other states of continental Europe. The army, on its peace footing, consists of permanent officers and of a constantly changing body of private soldiers. Every male German who is not physically incapacitated owes military service from the completion of his twentieth to the completion of his thirty-ninth year. The first seven years are passed (*a*) "with the colors" and (*b*) in the reserve. For the infantry, the period of service with the colors is two years; for the artillery and cavalry, three years. After completing his seven years in the active army and the reserve, the German passes for 12 years into (*c*) the *Landwehr.* Of these 12 years, the infantry soldier passes 5 years, the artillerist or cavalryman 3 years, in the first ban of the *Landwehr.* So long as he is enrolled in the reserve or in the first ban of the *Landwehr*, the citizen is liable to be called into camp from time to time for a period of a few weeks. From those citizens who for any reason have been excused from active service with the colors there is formed (*d*) a garrison reserve, with periodical training. After serving 12 years in the garrison reserve, its members are enrolled, until they are 39 years old, in the second ban of the *Landwehr.* In addition, every German between the completed seventeenth and the completed thirty-ninth year who is not enrolled in any of the four bodies above enumerated, belongs to (*e*) the first ban of the *Landsturm;* and every German between the completed thirty-ninth and the completed forty-fifth year belongs to (*f*) the second ban of the *Landsturm.* The *Landwehr* of the second ban and the *Landsturm* are summoned only in time of war. It should be added that young men who have obtained a higher education and who can

pay for their own equipment and maintenance, the so-called "volunteers," are held to but one year's service with the colors. In 1904 the standing army ("with the colors") numbered 29,404 officers, including surgeons, paymasters, etc.; 81,955 subaltern officers, and 495,500 men, not including the one-year volunteers. A law adopted 1 April 1905 provided for a gradual further increase of the standing army, so that by 1909 it should include, besides officers and volunteers, 505,839 men. Service in the ranks is regarded as a civic duty and is unpaid. In 1904, the appropriations for the army, excluding pensions and also the cost of expeditions to Southern Africa and to China, but including the non-recurrent expenditures, which figure to a varying amount in every budget, was 646,147,590 marks.

The German Navy.—A Prussian navy was started in 1844 with a single corvette. The revolutionary German government of 1848 built a fleet to fight the Danes, but in 1852 the Federal Diet ordered its dissolution and the ships were sold at auction. With the establishment of the present empire provision was again made for an imperial navy, and in 1880 this navy was reckoned the third strongest in the world. In 1897, however, Germany had fallen back to the sixth place. In the following year the emperor secured from Parliament authority for the building of a number of new vessels, and during the year 1900 a still more extensive programme of construction was sanctioned. In 1905 the navy included 26 armored warships, 8 armored coast guard vessels, 12 armored gunboats, 10 first-class cruisers, 32 second-class cruisers, and 43 miscellaneous vessels. The personnel consisted of 1,899 officers and 35,990 subaltern officers and men. Service in the navy, except as regards the officers, is unpaid. Like the active army, the active navy is a training school, and service at sea is an alternative method of discharging the universal duty of preparation for war. In 1904 the appropriation for the navy amounted to 99,301,578 marks for ordinary expenses and 129,268,970 marks for non-recurrent expenses. The latter item, of course, represented in the main the cost of new vessels under construction.

The German Dependencies.—Germany's foreign empire was started in 1884 and 1885 by the proclamation of a protectorate in various unoccupied territories in Africa and in the Pacific Ocean where German merchants had established themselves. Bismarck declared that these dependencies were not regarded by the imperial government as fields for German colonization, but as markets for the output of German industry. In 1897 Germany seized the harbor and city of Kiaochau and secured from the Chinese government a long lease of this city with the adjacent territory. It has since asserted a sphere of influence embracing the whole province of Shantung. In 1899 Germany purchased from Spain the Caroline, Pelew, and Ladrone Islands. In 1900, by arrangement with Great Britain and the United States, it established exclusive control over a portion of the Samoan group. According to statistics of 1903, Germany's African possessions, namely, Togo, Cameroon, German Southwest Africa and German East Africa, comprise 908,215 square miles of territory, with 11,447,000 colored and 6,757 white inhabitants. The German possessions in the Pacific, namely: New Guinea, Kaiser Wilhelm Land, the Bismarck archipelago, the Solomon and Caroline islands, etc., the Marshall and the Samoan islands, amount to 94,142 square miles, with 448,000 colored and 1,031 white inhabitants. The Kiaochau lease covers 213 square miles, with 120,041 Chinese and 3,735 white inhabitants. Thus far the dependencies have not been remunerative. In 1904–05 76,737,240 marks were appropriated for the administration of the dependencies, and of this sum 51,687,724 marks were to be supplied by the taxpayers at home. In addition, the imperial budget contained appropriations of 13,277,047 marks for military expeditions to Southwest Africa and Eastern Asia. Germany's exports to all these territories in 1903 were valued at 23,500,000 marks.

MUNROE SMITH,
Professor of Roman Law and Comparative Jurisprudence, Columbia University.

Germany, Rulers, Emperors, and Kings of. From the time of the "migration of the nations" in the latter part of the 5th century until the subjugation by Charlemagne, Germany was divided into numerous principalities or states, and therefore no "ruler of the whole people" was known until Charlemagne was proclaimed emperor in 800 A.D., though he himself had reigned over several states since 768. From that time until the present they have been as follows:

NAME	Dynasty	Date of Reign
Charles I., or Charlemagne the Great	Carlovingian	800–814
Lewis the Pious, or Louis "Le Débonnaire"	Carlovingian	814–840
Lothaire I.	Carlovingian	840–843
Lewis II. the German (king and emperor)	Carlovingian	843–876
Charles the Bald (Disputants)	Carlovingian	876–882
Louis the Stammerer (Disputants)	Carlovingian	
Louis II. (Disputants)	Carlovingian	
Carloman (Disputants)	Carlovingian	
Charles III. the Fat (king and emperor)	Carlovingian	876–887
Arnulf (Arnold I., king and emperor)	Carlovingian	887–899
Lewis the Child	Carlovingian	899–911
Conrad I.	Franconian	911–918
Henry I. the Fowler	Saxony	919–936
Otto I. the Great	Saxony	936–973
Otto II.	Saxony	973–983
Otto III.	Saxony	983–1002
Henry II. the Holy	Saxony	1002–1024
Conrad II. the Salique	Franconian (dynasty restored)	1024–1039
Henry III.	Franconian (dynasty restored)	1039–1056
Henry IV. (whose reign was interrupted by the four following)	Franconian (dynasty restored)	1056–1106
Rudolph of Swabia (elected by the Pope)	Franconian (dynasty restored)	1077–1081
Herman of Luxemburg	Franconian (dynasty restored)	1081–1087
Conrad (son of Henry IV.)	Franconian (dynasty restored)	1093–1098
Henry (son of Henry IV.)	Franconian (dynasty restored)	1105–1106
Henry V. (same as above)	Franconian (dynasty restored)	1106–1125
Lothaire the Saxon	Saxony	1125–1137
Conrad III.	Hohenstaufen	1138–1152
Frederick I. Barbarossa	Hohenstaufen	1152–1190
Henry VI.	Hohenstaufen	1190–1197
Philip of Swabia / Otto IV. (Jointly)	Hohenstaufen	1197–1208
Otto IV. (alone)		1208–1215
Frederick II. (whose reign was interrupted by the four following)	Hohenstaufen	1215–1250

NAME	Dynasty	Date of Reign
Henry (Landgrave of Thuringia) — Merely nominal	Hohenstaufen	1246–1247
William of Holland (elected by the spiritual electors) — Merely nominal	Hohenstaufen	1247–1256
Richard, Duke of Cornwall, England — Merely nominal	Hohenstaufen	1257–1272
Alphonso of Castile (never active) — Merely nominal	Hohenstaufen	
Rudolph	Hapsburg	1273–1291
Adolphus of Nassau	Hapsburg	1292–1298
Albert I. of Austria	Hapsburg	1298–1308
Henry VII	Luxemburg	1308–1313
Louis V. — Were contenders	Bavaria	1314–1347
Frederick the Fair — Were contenders	Austria	1314–1330
Charles IV	Luxemburg	1347–1378
Gunther, Count of Schwarzburg	....	1349
Wencelaus	Luxemburg	1378–1410
Rupert, Count Palatine	Bavaria	1400–1410
Sigismund of Brandenburg	Luxemburg	1410–1437
Jobst of Moravia (Pretender)	....	1410–1411
Albert II	House of Austria Hapsburg Dynasty	1437–1439
Frederick III	Hapsburg Dynasty	1440–1493
Maximilian I	Hapsburg Dynasty	1493–1519
Charles V	Hapsburg Dynasty	1520–1556
Ferdinand I	Hapsburg Dynasty	1556–1564
Maximilian II	Hapsburg Dynasty	1564–1576
Rudolph II	Hapsburg Dynasty	1576–1612
Matthias	Hapsburg Dynasty	1612–1619
Ferdinand II	Hapsburg Dynasty	1619–1637
Ferdinand III	Hapsburg Dynasty	1637–1657
Leopold I	Hapsburg Dynasty	1657–1705
Joseph I	Hapsburg Dynasty	1705–1711
Charles VI. of Bavaria	Hapsburg Dynasty	1711–1740
Charles VII. of Bavaria	Hapsb'g-Lorraine	1742–1745
Francis I	Hapsb'g-Lorraine	1745–1765
Joseph II	Hapsb'g-Lorraine	1765–1790
Leopold II	Hapsb'g-Lorraine	1790–1792
Francis II	Hapsb'g-Lorraine	1792–1806
William I.*	Hohenzollern	1871–1888
Frederick	Hohenzollern	1888
William II	Hohenzollern	1888–

* Between 1806 and 1871 utter chaos reigned and there was no responsible head of the government, the kingdom being again divided into "duchies."

Consult: Lewis, 'History of Germany' (New York 1874); Whitman, 'Imperial Germany' (1889); Sybel, 'Founding of the German Empire.'

Ger'micides, agents used to destroy or to hinder the growth of microscopical forms of plant and animal life.

Germicides may be grouped under three general heads, those that act mechanically, those that destroy life by physical means, and those whose action is chemical. Inasmuch as each particular germ is an individual with its own particular characters, definite methods for its killing must be devised. Thus it is well known that quinine, for instance, is very active in destroying animal parasites, such as the malarial organism, but it is practically of no service in combating a large number of vegetable forms; and *vice versa*, many substances which are capable of destroying plant germs are inefficient when applied to animals.

Of the physical agents, heat, light, cold, and electricity, heat is the most satisfactory. High degrees of temperature will destroy all forms of parasitic life. The animal forms succumb very readily to the influence of heat, and most of the plant parasites are destroyed by it; but whereas heat may be applied with great success as a germicide in general disinfection, it naturally cannot be used as a general agent on the body. The red-hot iron in the form of a galvanocautery, or a heated wire, makes a most efficient form of cautery to destroy the poison of dog-bite, or to destroy localized forms of tuberculosis, etc., but heat is thus limited in its application.

Cold is not an efficient germicide. Ordinary freezing temperature (32° F.) kills but very few forms of either plant or animal organisms. Even the extreme cold of liquid air does not kill bacterial spores.

Light, especially sunlight, is a very efficient germicide, but the exposure must be continued for an appreciable length of time. Sunlight is nature's great germicide. Within recent years the light given by the Röntgen ray (X-ray), by radium, polonium, thorium, and similar agents, has been used with great success in the treatment of certain parasitic skin-diseases, but whether the effects are due to any germicidal action of the light, or to a normal tissue stimulation, is not decided. It seems from experiments thus far recorded that these forms of light are not definite germicides. Various colored lights, particularly red and amber, are known to restrict the growth of certain forms of bacteria. They do not, however, destroy them. This principle is made use of in smallpox hospitals and similar institutions, but it does not seem that the results are sufficiently striking to base any general deductions thereon. Electricity is not an efficient germicide. The passage of electrical currents through water does not necessarily kill the bacteria contained therein, notwithstanding the many claims made by enterprising manufacturers of electrified water, said to be made germ-free by the electrical current. What the future may reveal along this line of experimentation it is impossible to prophesy, but thus far satisfactory evidence of the germicidal effects of electricity are lacking.

Chemical germicides are numerous, both for external and internal use, although intracellular germicides, or those that can be used within the tissues of the body, are much to be desired. The list of chemical germicides is enormous. Thousands of different agents have been used and these exhibit varying degrees of germicidal activity. As has already been said, each form of germ possesses its own powers of resistance, and each germicide its ability to kill in varying degrees of strength. The germicides in popular use are chlorinated lime, carbolic acid, creosote, alcohol, boracic acid, ammonia, formaldehyde, hydrogen peroxide, iodine and its preparations, mercury and its preparations, volatile oils of cinnamon, mustard, peppermint, turpentine, pennyroyal, oxygen, quinine, salicylic acid and its derivatives. Of these for external use, for use in closets, in bedding, for linen, etc., carbolic acid in the percentage of 1 to 50 of water, formaldehyde in percentage of a teaspoonful of the 40 per cent solution of the gas to a quart, bichloride of mercury in the proportion of 1 part to 1,000, are the most practical and convenient germicides. So far as is now known, quinine is about the only efficient chemical substance that can be used as an intracellular germicide. It has the singular property of poisoning the malarial parasites within the red blood-cell without poisoning the blood-cell itself, a selective property which most poisonous agents lack.

The great germicide of the human body, and the one that protects it in its various struggles with different forms of parasites is the blood-serum. This is a very efficient germicide, a full consideration of the action of which will be taken up under the heading of IMMUNITY. Consult: Buck, 'Reference Hand-Book of Medical Sciences' (1902), article on *Germicides;* Harrington, 'Practical Hygiene' (1901). See BACTERICIDE; BACTERIA; DISINFECTION; GERMS; IMMUNITY.

Germinal, zhăr-mē-näl, the 7th month of the first French republican calendar, 21 March–19 April.

Germina'tion, in botany, the first act of growth which takes place in an embryo plant. See SEED.

Gernsheim, Friedrich, frēd'rĭн gĕrns'hīm, German composer: b. Worms 17 July 1839. He studied at the Leipsic Conservatory, became an instructor in the Conservatory of Cologne in 1865, and in 1873 also Kapellmeister of the theatre there. In 1874 he was appointed director of the Rotterdam school of music, and in 1890 of the Stern Choral Union of Berlin. His works include chamber-music, three symphonies, and other instrumental compositions; the song-cycle 'Hafis,' for solo, chorus, and pianoforte; and various vocal compositions.

Gérôme, Jean Léon, zhŏn lā-ôn zhā-rōm, French painter: b. Vesoul, Haute-Saône, 11 May 1824; d. Paris 10 Jan. 1904. He was a pupil of Delaroche, who early credited him with originality and style. When he exhibited his 'Fighting Cocks' in 1847, Théophile Gautier wrote in *La Presse,* "Let us mark with white this lucky year, for unto us a painter is born." He followed Delaroche to Rome in 1848, and visited Russia and Egypt. He first showed his power in some Egyptian studies, but only reached the level of intensity and vividness which characterized all his succeeding work in his 'Duel after a Masked Ball.' This was followed by his 'Death of Cæsar.' In 1855 he exhibited 'The Age of Augustus,' a picture in which were harmoniously blended marvelous historic faithfulness with a powerful allegory by which the culmination of pagan civilization, and its gradual paling in the dawn of Christianity was finely suggested. His grasp of classic motifs was united to an extraordinary mastery of archæological detail, and his Roman 'Gladiators in the Amphitheatre' (1859), and 'Phryne before her Judges' (1861), are startling in the impression which they convey of antique life in its movement, sentiment, and passion. In this special department of historical genre Gérôme easily led the European painters of his century. See Claretie, 'Peintres et sculpteurs contemporains' (1884); Cook, 'Art and Artists of Our Time' (1888); Van Dyke, 'Modern French Masters' (1896).

Gerona, hā-rō'nä, Spain, a city and capital of the province of Gerona; 65 miles from Barcelona. It contains a beautiful Gothic cathedral of the 14th and 15th centuries. The town has undergone several notable sieges, particularly in 1653, 1684, 1694, 1706, and 1809, on each occasion by the French. Pop. 15,407. The province of Gerona has an area of 2,264 square miles. Pop. (1900) 299,287.

Geronimo, jĕ-rŏn'ĭ-mō, Apache chief of the Chiricahua band. In 1884–6 he became noted as the ring-leader in the harrying of Arizona and New Mexico (see APACHES). Gen. Crook forced him to a stand on 25 March 1886, but Geronimo refused to surrender except for two years, the band to be sent East with their families and then replaced on the old reservation. Crook accepted the terms and started for Fort Bowie, but on the march the entire band slipped away to the mountains and began the old forays again. The subsequent criticism of Crook, as the Indians' dupe against the protests of the settlers, caused his replacement by Gen. Nelson A. Miles, who gave the Indians no rest, till Geronimo once more surrendered, this time on condition of being sent out of Arizona. Gen. Miles ordered them sent to St. Augustine, but Geronimo and 14 others were sent to Fort Pickens, Fla., instead. He has since been held as a military prisoner at Fort Sill, Oklahoma.

Gerontes, gĕ-rŏn'tēs, in ancient Greece, a number of magistrates of Sparta who, with the ephors and kings, had the supreme power in the state. They were not eligible for election before they had attained the age of 60 years. Their number is variously stated at 20 and 32.

Gerrish, Theodore, American Methodist clergyman: b. Houlton, Maine, 19 June 1846. He served during the Civil War in the 20th Maine regiment, and was wounded four times; later entering the Methodist itinerant ministry. His publications include: 'Reminiscences of the War,' 'The Blue and the Gray,' 'Life in the World's Wonderland,' etc.

Gerry, gĕr'ĭ, **Elbridge,** American statesman: b. Marblehead, Mass., 17 July 1744; d. Washington, D. C., 23 Nov. 1814. He was a member of the Continental Congress 1776–80 and 1783–5; delegate to the constitutional convention in 1789; member of Congress from Massachusetts 1789–93; commissioner to France 1797–8; governor of Massachusetts 1810–12; and Vice-President of the United States 1813–14. It was during his term as governor that an unsatisfactory redistricting of the State took place, in which he was supposed to have taken part, whence arose the term "gerrymander" (q.v.). See Austin, 'Life of Elbridge Gerry, with Contemporary Letters' (1828–29).

Gerry, Elbridge Thomas, American lawyer and philanthropist: b. New York 25 Dec. 1837. He was graduated from Columbia in 1857, was admitted to the bar in 1860, and was a member of the State constitutional convention of New York 1867. Subsequently he became an associate of Henry Bergh in the American Society for the Prevention of Cruelty to Animals, of which he was for many years vice-president. In 1874 he was the leading organizer of the Society for the Prevention of Cruelty to Children, of which he was the president in 1876–91, and which became so closely identified with his name as often popularly to be termed the Gerry Society. He was chairman of the commission on capital punishment which substituted execution by electricity for that by hanging, in New York State (1886–8). He also held many important offices of trust, and became known for his interest in yachting affairs, having been commodore of the New York Yacht Club in 1886–93. He is a grandson of Elbridge Gerry (q.v.).

JEAN LÉON GÉROME.

Gerrymander, gĕr'ĭ-măn-dėr (hard g: now chiefly used as a verb), the arranging of election districts by one party in a State so as to concentrate its opponent's majorities and scatter its own, thus giving itself as many with light majorities and its rival as few with heavy ones as possible. Many States are to some extent gerrymandered by nature, the heaviest vote of one party being compacted into a minor section: Indiana and New York are notable cases — the one on account of the southern agricultural population having been kept from expansion by more energetic streams of a different character, the other from the development of a vast city at political odds with the rural parts. Law usually and fairness necessarily provide that the State shall be districted in solid blocks of contiguous territory, so that (subject to the above limitation) the district elections shall correspond roughly to the popular majorities in the State. But since early in the century, all parties in turn have often violated political equity by establishing artificial gerrymanders when in power; sometimes creating a popular revolt which has cost them the object of the scheme, but the rival party has rarely learned wisdom from that result, usually reversing the gerrymander for its own profit. As counties are fair models of what election districts should be, the gerrymander is generally worked by disregarding them; but the following illustration of its working with them is the simplest form. Suppose nine counties casting 10,000 votes each, the whole lying in a block thus arranged, and the votes divided between party A and party B as indicated within:

1 A 8750 B 1250	4 A 5250 B 4750	7 A 4850 B 5150
2 A 4500 B 5500	5 A 7500 B 2500	8 A 4750 B 5250
3 A 5100 B 4900	6 A 4300 B 5700	9 A 7000 B 3000

Now let one district be formed from the diagonal counties 1, 5, and 9, and three others, respectively, from 2 and 4, 3 and 6, and 7 and 8. Party A has 52,000 against B's 48,000 altogether or a popular majority of 4,000; but it only carries one district out of four because the gerrymander has made it waste most of its votes and its rival wastes almost none. Yet the law has been observed, as all the counties in each district are contiguous. Of course, in practice such perfect cases do not occur, and towns or counties are grouped raggedly in forms often grotesque. The origin of the name was from one of these, among the earliest. Massachusetts, in 1812, had its senatorial districts identical with the counties; the State Constitution gave the legislature the power of redistricting, however, and the Republicans, carrying the legislature in that year over the Federalists, at once gerrymandered it in a very outrageous fashion. The Boston *Sentinel* published a colored map of one district in Essex County, whose sprawling towns with a huge prong to the northwest seemed like some monstrous animal of fable; and on an indignant Federalist saying that it "looked like a salamander," another retorted, "Better call it Gerrymander," from the Republican governor, Elbridge Gerry (q.v.), whose signature had made it law. Gilbert Stuart (q.v.), the artist, drew a completion of it into an ungainly bird, which figured largely as a campaign document. The Federalists recaptured the legislature the next year and repealed the bill. The most famous of many great gerrymanders in the United States is the "Shoestring District" (Sixth Congressional) of Mississippi, formed to minimize the negro vote, and consisting of all the counties in the State touching the Mississippi River; it is about 300 miles long by an average of 20 broad.

Gerster, gär'stĕr, **Etelka** (MADAME GARDINI), Hungarian singer: b. Kaschau, Hungary, 16 June 1857. She was a pupil of Madame Marchesi in Vienna, and made her first appearance in Venice in 1876, as Gilda, in 'Rigoletto.' In 1878, and also in 1883 and 1887, she made successful tours in the United States. In 1887 she married her director, Pietro Gardini, and since 1896 has been at the head of a singing school in Berlin.

Gerstle, Lewis, Californian pioneer: b. Bavaria 17 Dec. 1824; d. San Francisco, Cal., 17 Nov. 1902. Coming to the United States as a lad, he settled in Louisville, Ky., and joined the fortune-seekers in California in 1850. With Lewis Sloss he subsequently formed the Alaska Commercial Company. Their enterprises by sea and land aided largely in building up California, and Gerstle always displayed a public spirit and faith in the future of the State. He was treasurer of the University of California, and identified with many Jewish and general charities, to all of which he was a generous giver.

Gertrude of Wyoming, a narrative poem by Thomas Campbell, written at Sydenham, in 1809. He chose the Spenserian stanza for his form of verse, and for his theme the devastation by the Indians, in 1778, of the quiet valley of Wyoming, in Pennsylvania, on the Susquehanna. The poem opens with a description of "Delightful Wyoming," which Campbell, who had never seen it, paints as a terrestrial paradise. The whole style and manner is pseudo-classic and old-fashioned; the treatment vague, unreal, and indefinite; but a certain sweetness and pathos, combined with the subject, has kept the poem alive.

Gervinus, Georg Gottfried, gā-ōrg' gŏtfrēd gĕr-fē'noos, German historian: b. Darmstadt 20 May 1805; d. Heidelberg 18 March 1871. In 1825 he went to the University of Heidelberg, where the lectures of Schlosser inspired him with a peculiar love of historical studies. In 1831 he visited Italy, where he remained for a year collecting materials for the works he was meditating. His 'Historische Schriften,' published after his return (1833), excited the attention of scholars, and secured him in 1835 an extraordinary professorship in the University of Heidelberg, where he was in 1844 appointed to an honorary professorship. From 1845 he took an active part on the liberal side in the movements then going on in Germany. It was at this period that he wrote his 'Mission der Deutschkatholiken' and 'Die Protestantische Geistlichkeit und die Deutschkatholiken.' In 1847 he founded in Heidelberg, in conjunction with Mathy, Mittermaier, and Häussy, the 'Deutsche Zeitung,' which at once became one of the leading organs of the party which advocated a representative system for Germany and a clearly defined federal constitution. His chief

works are 'Geschichte der poetischen Nationallitteratur der Deutschen' (1835–42), in which he endeavors to show how the development of German poetry is connected in all its phases with the history of the nation and other European countries; 'Shakespeare' (1849–50); 'Geschichte des neunzehnten Jahrhunderts' (1855–66). All his works, even his more purely æsthetical ones, such as that on Shakespeare, are more or less colored by his political views and aims. In the last years of his life he zealously endeavored to secure the popularity in Germany of the works of Handel, whom he regarded as the greatest genius in the musical sphere that the world had even seen. His 'Autobiography' appeared in 1893.

Geryon, jē'rĭ-ŏn, in the mythology of Greece a king of Hesperia, son of Chrysaor and Callirrhoe, a three-headed giant. He possessed numerous and fine herds, which were guarded by the two-headed dog Orthrus and the giant Eurytion. The herds were carried away, and Geryon slain by Hercules, in obedience to the command of Eurystheus.

Gesenius, Friedrich Heinrich Wilhelm, frĕd'rĭн hīn'rĭн vĭl'hĕlm gā-zā'ne-oos, German Orientalist: b. Nordhausen, Saxony, 3 Feb. 1786; d. Halle, 23 Oct. 1842. He studied at Helmstedt and Göttingen, and at Halle in 1810 became extraordinary, in 1841 ordinary, professor of theology. Here he lectured for more than 30 years, broken only by the closing of the university during the War of Liberation (1813–14), and by lengthened visits to France and England in 1820, to England and Holland in 1835. His first great work was his 'Hebrew and Chaldæan Hand Dictionary.' His 'Elementary Hebrew,' consisting of the 'Hebrew Grammar,' and the 'Hebrew Reader,' has contributed enormously to the knowledge of the Hebrew language, not only in Germany, but through translations also in England and the United States. Later works are his 'Critical History of the Hebrew Language and Literature' (1815); 'On the Origin, Genius and Authority of the Samaritan Pentateuch' (1815); 'A Critical Grammatical System of the Hebrew Language' (1817), and a new translation of and commentary on Isaiah (1820–21). His greatest work is the monumental 'Critical Grammatical System of the Hebrew and Chaldæan Languages in the Old Testament,' of which the first part was published in 1829, but which was completed only in 1858 by Rödiger. See Hayne, 'Gesenius, eine Erinnerung für seine Freunde' (1842).

Gesner, Abraham, Canadian geologist: b. Cornwallis, N. S., 2 May 1797; d. Halifax, N. S., 19 April 1864. He studied medicine in London, and returned to Nova Scotia. Later he became interested in scientific researches. In 1838 he was appointed to examine and report on the geological resources of the lower provinces of British North America. Afterward he discovered how to produce oil suitable for lamps from bituminous shale and cannel coal. He thus originated the discovery of "kerosene" (which name he gave his oil) in the United States. His publications include: 'Remarks on the Geology and Mineralogy of Nova Scotia' (1837); 'Reports on the Geological Survey of the Province of New Brunswick' (1844); 'New Brunswick, with Notes for Emigrants' (1847); 'Industrial Resources of Nova Scotia' (1848); 'A Practical Treatise on Coal Petroleum and Other Distilled Oils' (1861); etc.

Gesner, Konrad von, kōn'räd fōn gĕs'nĕr, Swiss naturalist: b. Zürich, Switzerland, 26 March 1516; d. there 13 Dec. 1565. His early studies, in medicine, natural history, and Greek and Latin literature, were prosecuted at Zürich, Strasburg, Bourges, and Paris, and in 1537 he was appointed professor of Greek at Lausanne. This chair he exchanged four years later for that of physics and natural history at Zürich. He was an indefatigable writer of books and in the course of his life published no less than 72 works, besides leaving at his death 18 others in progress. His 'Universal Library' (1545), contained the titles of all the books then known in Hebrew, Greek, and Latin, unpublished as well as published, with criticisms and summaries of each. His next undertaking was the 'Animal History' (1551–8). The first book treats of viviparous quadrupeds, the second of oviparous animals, the third of birds, and the fourth of fishes and aquatic animals. He collected more than 500 plants undescribed by the ancients, and appears to have been the first who made the great step toward a scientific classification of distinguishing genera by the fructification. He also wrote on other branches of science, as medicine and mineralogy, and composed a great number of works dealing with the ancient classics, the 'Mithridates sive de Differentia Linguarum' (1555) being the most notable.

Gessler, gĕs'lĕr, **Albrecht**, or **Herman**, called also Gessler von Bruneck, legendary Austrian official, in 1300 appointed joint-governor with Berenger von Landenberg, of the Waldstädten or forest cantons (Schwytz, Unterwalden, and Uri), by Albrecht I. of Austria. According to the traditions connected with William Tell (q.v.), his oppressive edicts and wanton cruelty so enraged the inhabitants that a conspiracy was formed against him, and he was shot by Tell in a narrow pass near Küssnacht in 1307.

Gessner, gĕs'nĕr, **Salomon**, German poet, painter, and etcher: b. Zürich 1 April 1730; d. there 2 March 1788. In 1762 he published, in four volumes, the poems which he had previously given to the world on different occasions. In 1772 he published another volume containing a collection of poems, to which he gave the name of 'Idyllen' (idyls), a name which he had already given to a previously published volume of poems. Their quiet, amiable character pleased many in Germany; and in France, where they were translated by Huber, they were received with enthusiasm, and the author was regarded as a poet of the first rank. From France his fame spread over all Europe. The most popular of his idyls is the 'Death of Abel,' since translated into many foreign languages. In landscape painting he has merits which no age will diminish. His etching is light and powerful; his views are select, wild, and romantic; and his trees are particularly fine. Twelve engraved landscapes, published in 1770, are considered among his best works.

Gesta Romanorum, jĕs'ta rō-mä-nō'rŭm, 'Deeds of the Romans,' the title of a collection of short tales, legends, etc., in Latin, very popular

in the Middle Ages. The book was probably compiled about the close of the 13th century. The separate tales making up the Gesta are of diverse contents, and belong to different times and countries, the sources from which they are derived being partly classical, partly Oriental and partly western. Whatever may have been the intention of the original compiler, they very soon were adapted to the moralizing tendencies of the time, and moral reflections and allegorical interpretations were added to them, it is said, by a Petrus Bercorius or Pierre Bercaire of Poitou, a Benedictine prior.

Gesta'tion, the period of development of the fœtus from the time of conception to birth. Even in animals, where only a single insemination is allowed, the length of the gestation cannot always be foretold with exactness. The human fœtus is carried in the uterus about 280 days. For periods of gestation in animals, see BREEDING. See also OBSTETRICS; PREGNANCY.

Geta, jē'ta, **Septimus,** Roman emperor: b. 189 A.D.; d. 211 A.D. He was the second son of the Emperor Severus, and brother of Caracalla, with whom he was associated in the empire on the death of his father. Caracalla, who envied his virtues and was jealous of his popularity, after having endeavored to effect his death by poison, murdered him, and wounded their mother, who was attempting to save him.

Gethsemane, gěth-sěm'a-nē, or **Gethsemani** (*Boustanez-Zeitoun*), an olive garden or orchard in the neighborhood of Jerusalem, on the road leading from the brook Kedron to the Mount of Olives. The place is noted for being the scene of «Our Lord's Agony in the Garden» (Luke xxiii. 39–53). It is said that when St. Helena (q.v.), the mother of Constantine, visited the Holy Land in 425, she found abundant evidences to aid her in locating the exact site of the «Garden of Olives» or Gethsemane. The place is now in possession of the Franciscan Fathers of the Holy Land who, in 1848, built a wall around it the better to protect it. They have planted many flowers which they give gratuitously to travelers who desire some memento from this historic spot. Maudrell described the place in his day (1697) as «well planted by olive trees»; but there are now only eight trees which are supposed to have been in the grove at the time of our Lord. Some historians seek to throw doubts upon the age of these trees because of the order issued by Titus to destroy all the trees within a certain limit. These trees were so near the walls that they could not well be destroyed even if the tops were cut off. From the earliest days of the possession of Palestine by the Mohammedans every olive-tree has been taxed except these trees. In the 17th century there were nine trees, but one was destroyed by tourists. The present appearance of the garden is in accordance with the description as found in the Gospels. Another site, a little to the north, is claimed by some to be the real Gethsemane. Consult: De Hamme, 'Ancient and Modern Palestine'; Vogue, 'Les Eglises de la Terre Sainte,' p. 314; Thomson, 'The Land and the Book'; Costello, 'The Gospel Story.'

Getty, George Washington, American soldier: b. Georgetown, D. C., 2 Oct. 1819; d. Forest Glen, Md., 3 Oct. 1901. He was graduated from the United States Military Academy in 1840, fought in the Mexican and Seminole wars, in the Civil War attained the brevet rank of major-general, United States army. He subsequently was commander of numerous military districts; was transferred to the artillery in 1871 and retired from the service in 1883.

Get'tysburg, Pa., a borough and county-seat of Adams County; 35 miles southwest of Harrisburg; on the Philadelphia & R. and Western M. R.R.'s. It is the seat of a Lutheran theological seminary founded in 1826, and Pennsylvania College (Lutheran) founded 1832. One of the most famous battles of the Civil War was fought here. Pop. (1900) 3,495. See GETTYSBURG, BATTLE OF.

Gettysburg, Campaign and Battle of. After the battle of Chancellorsville (q.v.), 1–3 May 1863, the opposing armies resumed their positions on the Rappahannock, Lee's army on the south side of the river, at Fredericksburg, Hooker's on the north side, opposite. Encouraged by victory, and desiring to relieve Virginia of the presence of the Union army, Lee determined to transfer the seat of war north of the Potomac. His army, 1 June, was composed of the three corps of Longstreet, Ewell and A. P. Hill, and Stuart's cavalry force of 12,000 men, in all about 76,000 men, with 190 guns. Hooker's Union army was composed of seven corps, the First, commanded by Reynolds; Second, by Hancock; Third, by Sickles; Fifth, by Meade; Sixth, by Sedgwick; Eleventh, by Howard; and Twelfth, by Slocum; aggregating, 10 June, 82,000 infantry and artillery «present for duty and equipped,» with 410 guns, to which were added Pleasonton's cavalry force of about 12,000.

Lee began his campaign 3 June by sending Longstreet and Ewell to Culpeper Court House, where the cavalry, under Stuart, was also concentrated. A. P. Hill remained at Fredericksburg to watch and detain Hooker. Hooker suspected Lee's movement and, under his direction, Sedgwick laid bridges, crossed the river, and reported that Lee's main body seemed to be still there. Pleasonton was ordered to feel the position at Culpeper. Reinforced by two infantry brigades, he crossed the Rappahannock on the morning of the 9th, encountered Stuart at Fleetwood and Brandy Station (see FLEETWOOD AND BRANDY STATION, BATTLE OF), and reported the greater part of Lee's army at Culpeper, preparing to move on Washington. Hooker sent three corps up the Rappahannock to prevent Lee's crossing. On the 10th Lee sent Ewell, preceded by two brigades of cavalry, to the Shenandoah Valley to clear it of Union troops. Ewell defeated and dispersed Milroy's command at Winchester (see WINCHESTER, BATTLE OF), took Martinsburg and cleared the valley; and on the 15th Rodes' division crossed the Potomac at Williamsport, sending Jenkins' cavalry brigade in advance to Chambersburg, and on the 19th moved to Hagerstown. Johnson's division crossed the Potomac and marched to Sharpsburg, and Early's moved to Shepherdstown to threaten Harper's Ferry. In these positions Ewell waited until the 21st for the other two corps to close up, when he advanced to Chambersburg. Longstreet moved from Culpeper on the 15th and, advancing along the east side of the Blue Ridge, occupied Ashby's and Snicker's Gaps. Stuart's cavalry was thrown out in front of Longstreet to watch Hooker, and

on the 17th had a severe fight with the Union cavalry at Aldie and was driven back to Middleburg. A series of cavalry combats ensued, at the end of which Stuart was driven behind the Blue Ridge. On the 24th Longstreet moved by way of Berryville, crossed the Potomac at Williamsport on the 25th and 26th, and marched to Hagerstown, thence on the 27th to Chambersburg. A. P. Hill remained at Fredericksburg until the 14th, when, Hooker having fallen back, he moved down the Shenandoah Valley, crossed the Potomac at Shepherdstown, and joined Longstreet at Chambersburg. Stuart was left to guard the passes of the Blue Ridge and watch Hooker, whom he was to harass as much as possible, should he attempt to cross the Potomac. Meanwhile Hooker, starting from the Rappahannock on the 13th, was moving cautiously back toward the Potomac and covering Washington. On the 25th, 26th and 27th he crossed the Potomac at Edward's Ferry, near Leesburg, and on the 28th his army was grouped about Frederick, with Slocum's corps on the left near Harper's Ferry. He desired to send Slocum's corps and the 10,000 men, composing the garrison at Harper's Ferry, against Lee's rear, but Gen. Halleck, commander-in-chief, refused the request for the garrison, and Hooker asked relief from command. His request was promptly granted, and 28 June Gen. George G. Meade was assigned to the command. Halleck granted Meade's request to utilize the garrison at Harper's Ferry and Meade ordered the abandonment of the place and the transfer of the garrison to Frederick and Washington.

Lee, deprived of the use of his cavalry, had been unable to get information of Hooker's movements; and to retain him on the east side of the mountains, after he had entered Maryland, Ewell had been instructed, on the 24th, to send a division across the South Mountain to threaten Baltimore. Early's division, detailed for the purpose, went as far east as York, the other two divisions of the corps marching from Chambersburg to Carlisle. Jenkins' and White's cavalry were in advance at Wrightsville and above on the Susquehanna, threatening to cross and take Harrisburg. Lee now made preparations to advance upon Harrisburg, but, on the night of the 28th received information that the Union army had crossed the Potomac and was moving northward, its head of column already at South Mountain. His communications thus menaced, Lee resolved to prevent the further progress of the Union army by concentrating his own on the east side of the mountains; accordingly Ewell was ordered to turn back from the Susquehanna, Carlisle, and York, and march for Gettysburg, and Longstreet and Hill were directed to march from Chambersburg to the same place. On the night of the 30th Rodes' division of Ewell's corps was at Heidlersburg, eight miles northeast of Gettysburg, with Early's and Johnson's divisions near. Hill was at Fayetteville and Cashtown, eight miles from Gettysburg, and Longstreet was still at Chambersburg.

On the morning of the 29th under the impression that all of Lee's army was along the Susquehanna, Meade marched by three divergent roads in that direction and on the night of the 30th his forces were thus distributed. Buford, with two brigades of cavalry, was in advance at Gettysburg; Reynolds' First corps on Marsh Creek, five miles southwest of Gettysburg; Sickles' Third corps at Taneytown, and Howard's Eleventh corps at Emmitsburg. These three corps, constituting the left wing of the army, were under command of Gen. Reynolds. Hancock's Second corps was at Uniontown; Sykes' Fifth corps at Union Mills; Sedgwick's Sixth corps at Manchester; and Slocum's Twelfth corps at Littlestown. Gregg's cavalry division was at Westminster. Kilpatrick's division, after a spirited fight with Stuart's cavalry at Hanover, bivouacked near that place. When Buford reached Gettysburg he went into camp just beyond the western limits of the town and threw out skirmishers three miles west and north.

The First Day's Battle.— Heth's division, the advance of Hill's corps, moved from Cashtown at 5 o'clock on the morning of 1 July, coming in sight of Buford's skirmishers about 9 o'clock, at which hour Buford fired his first gun as a signal for his skirmishers to open fire, and the battle of Gettysburg began. Heth advanced and Buford was slowly driven back, contesting every foot of ground, until Reynolds came up with Wadsworth's division, which became immediately and desperately engaged. During this encounter Reynolds was killed. Doubleday succeeding to the command of the First corps, continued the contest. The other two divisions of the corps came up at 11 o'clock, followed at 12.45 by Howard's corps, one division of which was placed in reserve on Cemetery Hill, the other two forming on Doubleday's right along Seminary Ridge. Meanwhile Hill had arrived with the remainder of his corps, and Ewell, arriving at 2.30 P.M. with Rodes' and Early's divisions, formed on Hill's left. Hill made successive assaults on Doubleday from the west, and Ewell upon Howard from the north, which were repulsed; but finally, after desperate fighting and great losses on both sides, Early struck Howard in flank, causing him to give way, and the entire Union line was driven back through the town to Cemetery Hill, about half a mile south, which had been chosen by Howard as a rallying point for the two corps, and upon which he had placed one of his own divisions. When Meade heard that Lee's advance had reached Gettysburg, and that Reynolds had been killed, he was at Taneytown, 14 miles away, preparing to take up a defensive line along Pipe Creek. He ordered Hancock to ride forward and take command at Gettysburg. Hancock arrived as the Union troops were retreating through the town, was struck with the advantages presented by Cemetery Ridge for a defensive battle, determined to hold it and so notified Meade, sent one of Doubleday's small brigades to hold Culp's Hill, on the right, and made an ostentatious display of Buford's cavalry on the extreme left: which show of force, and the great loss — over 7,000 — sustained by the Confederates during the day, caused Lee to defer operations. Two divisions of Sickles' corps came up at dark; Slocum's corps came about the same time, and Slocum, as ranking officer, assumed command of the field, Hancock riding back to report to Meade that Gettysburg — to which point Meade had already ordered the concentration of his army — was the proper place to fight a battle. Hill's and Ewell's

NEW YORK STATE MONUMENT IN NATIONAL CEMETERY, GETTYSBURG, PA.

Confederate corps were all up by night, and Longstreet bivouacked four miles in rear of Hill.

The Second Day.— Gen. Meade arrived on the field at 1 o'clock on the morning of the 2d. All his troops except the Sixth corps were up by noon. The Sixth corps, having 34 miles to march from Manchester, did not come up until between 2 and 4 o'clock in the afternoon. The position on which Meade disposed his army was in the shape of a fishhook. As finally posted, the Twelfth corps was on the right at Culp's Hill, facing east; Wadsworth's division on its left, facing north; the Eleventh corps on Cemetery Hill, on the left of Wadsworth, its right facing northeast, its centre and left facing northwest, with Robinson's division of the First corps on its left. Doubleday's division in reserve. The Second corps, facing west, was on the left of Robinson; the Third corps on the left of the Second, with the Fifth, later in the day, on the extreme left. The Sixth corps was in rear of Round Top, on the left, as a reserve. Sickles, not satisfied with the position assigned the Third corps, moved to the front about three fourths of a mile, from where Meade would have recalled him, but it was too late to do so in presence of a vigilant enemy.

The main part of Lee's army was on Seminary Ridge, a short mile west of Meade's left and centre; Longstreet on the right, with Hill on his left. Ewell's corps on the left held the town, and was at right angles to Hill and Longstreet. Pickett's division of Longstreet's corps had not come up. Skirmishing began in the morning. At 4 o'clock in the afternoon the battle opened by Longstreet's advance. He attacked Sickes with great fury and, although reinforced by Caldwell's division of the Second corps, and Barnes' and Ayres' divisions of the Fifth, after heavy fighting and great losses the Third corps and its supports were driven back beyond the main line. Longstreet followed, but was checked by a charge of Crawford's division of the Fifth corps and the firm and solid appearance of the Sixth corps. On Longstreet's right Hood's division advanced to seize Round Top, but was repulsed by Vincent's and Weed's brigades of the Fifth corps. Vincent and Weed were killed, and Hood wounded. During the latter part of Longstreet's engagement with Sickles two of Hill's brigades assailed Hancock's line and broke it, but were soon driven back. At about the same time Hays' and Hoke's brigades of Early's division assaulted Howard's line on Cemetery Hill, but were driven back with the assistance of two regiments and Carroll's brigade of Hancock's corps. Still further on the Confederate left Johnson's division of Ewell's corps assaulted Culp's Hill, then held by Wadsworth's division of the First corps and Greene's small brigade of the Twelfth corps, the rest of the corps having been withdrawn and sent to the assistance of the left. Johnson's right, continuing the fight until late in the night, was repulsed, but his left entered, unopposed, the strong works thrown up by the Twelfth corps, and was perilously near the practically unguarded reserve artillery and ammunition train of the Army of the Potomac. Upon the return of the Twelfth corps during the night to its former position, finding it occupied, it waited until daylight before attempting to retake it. Meanwhile Johnson was being reinforced by three brigades, that he might hold his ground and renew his fight.

The Third Day.— The battle of the third day began by a struggle of the Twelfth corps to regain their works. At 4 A.M. the corps artillery, five batteries, opened a furious fire upon Johnson, at a range of 600 to 800 yards, other batteries followed, in the midst of which Johnson attacked the left of the Twelfth corps and the right of Wadsworth's division; the combat extended to the right, was taken up by Williams' division, and for six hours the struggle continued, at the end of which Johnson was repulsed. At 10.25 Johnson massed his forces in column of regiments and made a determined assault upon the right of Geary's division, by which, with the assistance of Shaler's brigade, he was repulsed, and driven beyond Rock Creek with a loss of nearly 2,000 killed and wounded, and three colors. At 11 o'clock the battle ceased on the Union right, with the Twelfth corps line fully re-established. There was more spectacular fighting on other parts of the field, but none more desperate and bloody than on the wooded Culp's Hill. Meanwhile Lee was preparing an attack upon the left centre of Meade's army. Pickett's division had now come up, and Longstreet was directed to form a column of assault composed of Pickett's division, Pettigrew's division, and two brigades of Pender's division, under Trimble, of Hill's corps. To prevent Meade from reinforcing the threatened point, Stuart's cavalry was ordered to go around Meade's right and attack his rear; 135 guns were disposed on Seminary Ridge; and at 1 P.M. the signal-gun was fired, and the 135 guns opened fire to crush out all opposition at the point to be attacked; the fire was replied to by 85 Union guns, and for two hours the hills shook and the earth trembled. As soon as the Union fire slackened, the great column of attack moved forward, Pickett's division on the right and Pettigrew's on the left. Pettigrew was supported by the two brigades of Trimble, and Pickett by the brigades of Wilcox and Perry. Pickett and Pettigrew, at the start from Seminary Ridge, covered a front of 1,600 yards; they had 1,400 yards of open ground to traverse before reaching the Union line; and the assaulting column numbered 14,000 men. As soon as it started, the Union artillery opened on it with shot and shell, tearing great gaps in the line; as it came nearer, canister did its deadly work; it was attacked on both flanks; and as it approached the Union line, held by Gibbons' and Hays' divisions of Hancock's corps, a flame of musketry burst forth before which nothing could live, and the men began to retreat; but, on the right, Armistead, commanding one of Pickett's brigades, broke the Union line and, with less than 100 men, crossed the Union works and seized a gun; a short hand-to-hand encounter ensued; Armistead was killed, and his small party killed or captured. Pickett saw the failure of his assault, and ordered a general retreat, after losing over 5,000 men. Wilcox's and Perry's brigades, which should have supported Pickett's right, were not prompt in starting, became separated from it and, attacking the right of the First corps, were driven back, los-

ing many prisoners, and the battle of Gettysburg was ended. On the Union right Gregg's cavalry division, aided by Custer's brigade, defeated Stuart, after a severe fight, and thwarted his attempt on Meade's right and rear. On the left Kilpatrick, with two cavalry brigades, recklessly charged Confederate infantry in dense woods, and behind stone fences, west of Round Top, in which assault Gen. Farnsworth, commanding one of his brigades, was killed. On the morning of 4 July Lee withdrew from his advanced positions, put his trains in motion for the rear, retreated at night and; followed and harassed by the Union cavalry, reached Williamsport on the 7th; but as the pontoon bridges had been destroyed and the Potomac had risen, he was unable to cross, and so entrenched. Meade followed by a circuitous route through Frederick and, after some delay, again confronted Lee on the 13th. He was about to attack when Lee recrossed the Potomac on the night of the 14th, his rear-guard, under Gen. Pettigrew, being attacked by Kilpatrick, during which fight Pettigrew was mortally wounded and many prisoners were taken.

From first to last the Union forces on the field numbered about 88,000 effective men; the Confederate forces on the field numbered about 73,000 men. As officially reported, the Union loss was 3,072 killed, 14,497 wounded, and 5,434 missing; an aggregate of 23,003; the Confederate loss 2,592 killed, 12,709 wounded, and 5,150 missing; an aggregate of 20,451. E. A. Carman.

Geulincx, hė'lĭnks or zhė-läṅks, **Arnold**, Dutch philosopher: b. Antwerp, 1625; d. Leyden 1669. He was one of the disciples of Descartes (q.v.), and a leading exponent of the speculative doctrine known as Occasionalism. For 12 years, from 1646, he lectured successfully at Louvain, was then deposed for some reason not ascertained, and, after living at Leyden in great distress, was in 1665 appointed professor of philosophy there, but died four years later. His ideas are expounded in books entitled: 'Saturnalia'; 'Logica'; 'Ethica,' published in his lifetime, and in 'Annotata præcurrentia ad Cartesii Principia' (1690), and 'Metaphysica Vera' (1691), which appeared after his death. The salient point of his teaching is an endeavor to explain the relations which obtain between soul and body, the mutual interaction of which under stimulus he ascribed to divine intervention and preordained arrangement. See Grimm, 'Arnold Geulincx'; 'Erkenntnisstheorie und Occasionalismus' (1875); Pfleiderer, 'Arnold Geulincx als Hauptvertreter der Occasionalistischen Metaphysik und Ethik' (1882).

Geum, jē'ŭm, a genus of *Rosaceæ*, sub-order *Potentilleæ*, distinguished from *Potentilla* by the hardened hooked styles which crown the carpels, so that the fruit becomes a burr. They are perennial herbs with pinnate or pinnatifid leaves, and white, yellow or purple flowers. There are about 40 species, 14 being found in North America. They are commonly known as avens. The roots of *G. rivale*, purple or white avens, and of *G. urbanum* have astringent and tonic properties. The latter is used for flavoring ale. *Geum strictum* is known as chocolate-root. Many of the species are cultivated, *G. chiloense* being especially ornamental.

Geyserite, gē'sėr-īt, or **Siliceous Sinter**, is amorphous silica containing a varying amount of water. It is white or grayish in color, and is deposited about the geysers and hot springs of Wyoming, Montana, Iceland, and New Zealand as hard masses or in filamentous or cauliflower-like forms sometimes of great beauty. In the Upper Geyser Basin in the Yellowstone Park the formations of geyserite are abundant and most beautiful. The great terraces of the Mammoth Hot Springs are not geyserite, but are chiefly calcareous deposits.

Geysers, a name derived from an Icelandic word signifying "to burst forth with violence," and applied to natural springs of hot water of the kind that were first observed in Iceland, and since in Wyoming and California in the United States, and in New Zealand. They may be described as volcanoes of hot water, for they resemble volcanoes in every particular — in the vibrations of the earth and dull rumbling sounds or loud reports by which the eruptions are preceded, in the intermittence of the phenomenon, and in the form of the opening at which the eruptions take place, like an inverted cone with a deep central throat. Natural philosophers are not agreed as to the mode in which this phenomenon is to be explained, but the most generally prevailing and most probable hypothesis is that it is caused by the disengagement of large quantities of vapor, which force the water up into the air when the successive disengagements have produced a sufficient pressure.

The geysers of Iceland lie about 30 miles west of Mount Hecla, and 16 miles north of the town of Skalholt, in a plain covered by hot-springs and steaming apertures. They are nearly 100 in number, and are scattered over a surface scarcely more than two square miles in extent. The two most remarkable are the Grand Geyser and the New Geyser or *Strokkur* (churn). The Great Geyser rises from a tunnel-shaped basin, lined and edged with silicious deposits. The pipe or throat at the bottom, from which the jet issues, is about 10 feet in diameter, and the basin at its outer edge is above 70. The emissions generally take place at intervals of six hours, and last for about five minutes at a time. The column, as measured by a quadrant, has been seen to rise as high as 212 feet. It is impossible to fix the age of the Great Geyser, but that its eruptions have taken place from the most remote antiquity is proved by the fact that, although there has been no sensible increase in the depth of the silicious deposit since the earliest recorded observations, it is now more than 16 feet deep.

The geysers of Iceland, long the only ones known to exist, are surpassed by those which have been discovered in comparatively recent times in the Yellowstone National Park. The largest of them is called the Grand Geyser. It begins an eruption by filling its basin with boiling water, forming a well 20 by 25 feet in diametric measurements, and having a visible depth, when quiet, of 100 feet. The explosion is preceded by clouds of steam rushing up to a height

OLD FAITHFUL GEYSER, IN YELLOWSTONE PARK.

of 500 feet; the great unbroken body of water succeeds, ascending in one gigantic column to a height of 90 feet; while from the apex of the column there radiate five great jets, which shoot up to the unparalleled height of 250 feet from the ground. Among the other remarkable geysers of this district are those named Old Faithful, the Beehive, the Giant, the Giantess, etc. The number of hot-springs in the Yellowstone is not less than 1,500, all varying in times of action, force, deposits, and color of water.

Ghaleb, gä-lēb', the last of the great poets of the old Turkish school. His 'Husn-u-Ashk' (Beauty and Love), written about 1800, has been called one of the finest productions of Ottoman genius.

Ghavial, găv'ĭ-al. See GAVIAL.

Ghee, gē, or **Ghi**, a peculiar kind of butter in use among the Hindus. It is made in the following manner: The milk when brought from the cow is poured into earthen vessels, in which it is boiled for one hour, often for two or three hours. It is then put in a cool place, and a little curdled milk is added. By the next morning the whole is converted into sour curdled milk. A layer 5 or 6 inches deep is then taken off the top of the contents of each vessel, and is put into another larger vessel, in which the whole mass is gently stirred for half an hour with a split bamboo-cane. A little warm water is then added, and the stirring is continued for another half-hour, when the butter begins to form. After being kept for three days — a period long enough for the butter to become rancid in so hot a climate — it is melted in another earthen vessel, and boiled until all the water it contains is evaporated. A little more curdled milk is then added, along with some salt or betel-leaves, and the butter, which is now ready, is then put in pots, in which it is kept till required. In this state it will keep for a long time, being sometimes used a year after it is made. This butter has naturally a very strong taste, insupportable to a European stomach, but it is in general use among the Hindus who are rich enough to buy it, and is an important article of commerce.

Ghent, gĕnt, Belgium (French, Gand; Flemish, Gend or Gent, capital of the province of East Flanders, at the confluence of the Lys with the Scheldt. It is upward of six miles in circumference, and is divided by canals into a number of islands connected with each other by bridges. Except in some of the older parts, it is well built, and has a number of fine promenades and many notable buildings. Among the latter are the cathedral of St. Bavon, dating from the 13th century; the church of St. Nicholas, the oldest in Ghent; the church of St. Michael, with a celebrated Crucifixion by Van Dyck; the university, a handsome modern structure, with a library of about 100,000 volumes and 700 manuscripts; the belfry, a lofty square tower surmounted by a gilded dragon, and containing chimes of 44 bells; the Marché du Vendredi, an extensive square, interesting as the scene of many important historical events; and Les Béguinages, extensive nunneries founded in the 13th century, the principal occupation of whose members is lace-making. Ghent has long been celebrated as a manufacturing town, especially for its cotton and linen goods and lace. Other industries of importance are sugar-refining, hosiery, thread, ribbons, instruments in steel, carriages, paper, hats, delftware, and tobacco. There are also machine works, engine factories, roperies, tanneries, breweries, and distilleries. The trade is very important. A canal connects it with the Scheldt at Terneuzen. Another canal connects the Lys with the canal from Bruges to Ostend. Ghent was mentioned as a town in the 7th century. In the 9th century Baldwin, the first Count of Flanders, built a fortress here against the Normans. Under the counts of Flanders Ghent continued to increase. Two great revolts took place under the leadership of the Van Arteveldes (1338 and 1369) against Burgundy, and again in the 16th century against Charles V., and the citizens of Ghent, besides losing their privileges, had to pay for the erection of a citadel intended to keep them in bondage. In 1792 the Netherlands fell under the power of France, and Ghent became the capital of the department of Escaut (Scheldt). In 1814 it became, along with Flanders, part of the Netherlands, till the separation of Belgium and Holland. Pop. (1900) 160,949.

Ghent, Treaty of (24 Dec. 1814), the treaty which closed the War of 1812. The British advantage was enormous: the war had been discreditable and rather disastrous to America on land, and was half paralyzed by incompetent administration and dissensions among the States; while even the fleet had not maintained its early triumphs; the overthrow of Napoleon had let loose an irresistible army, and had they persevered they might almost have exacted their own terms. But the British were tired of the burdens of a 20-years war, and the ministers were anxious like them to have done with fighting and settle down to peace; and the American privateers and navy were injuring their commerce unbearably. To our good fortune, also, they had the old-fashioned British contempt for American diplomatic ability, and sent third-rate negotiators to Ghent — Lord Gambier, an ex-naval captain, a junior lord of the admiralty, entirely inexperienced in foreign affairs; Henry Goulburn, a young under-secretary of state, narrow and lacking self-control; and William Adams, an unknown lawyer. America, on the other hand, sent some of the strongest men in the country: John Quincy Adams, James A. Bayard, Henry Clay, Jonathan Russell, and Albert Gallatin, men with no superiors in the world in ability, experience, knowledge, and clearness of purpose, and three at least unsurpassed in tenacity of will. In 1813, when Russia offered mediation, Bayard and Gallatin went to St. Petersburg to negotiate, but England refused the offer. Their instructions had included an article against impressment; but as it was notorious that the Napoleonic wars alone made this a practical question, and those were now ended, the government allowed them to waive that point. The British claims at first set up were impossible: the establishment of the boundary fixed by the Indian Treaty of Greenville in 1795 (see GREENVILLE, TREATY OF), as a permanent line beyond which neither party should acquire territory, thus cutting off the entire Northwest from the United States; the cession of the mouth of the Niagara and Sackett's Harbor, in New York, prohibiting the United States from keeping land or naval forces on the Lakes; and allowing free navigation of the Mis-

sissippi to England. Finally the struggle of the entire autumn and early winter ended in this treaty, which was scarcely more than an agreement to cease hostilities and settle the disputed questions at some other time. The questions of impressment, on which the war had been opened; of the extent of the right of blockade; of the American right to fish in British waters; of the British navigation of the Mississippi, and trade with the Indians; of the armaments on the Lakes; of the American claim for British spoliations; all were silently passed over. The treaty, as ratified 17 Feb. 1815, and proclaimed on the 18th, restored the *status quo* of territorial possessions except some islands in Passamaquoddy Bay — public or private property in the surrendered places not to be destroyed or removed, provided a commission to decide on the ownership of the islands above, the matter to be referred to arbitration if they failed to agree; and other commissions to settle the boundaries provided in the Treaty of Paris (1783) — from the St. Croix to the St. Lawrence at lat. 45° N., thence to Lake Superior, and from St. Mary's River to the Lake of the Woods. The last article binds both parties to use their best endeavors to suppress the slave trade.

Ghent, University of, Belgium, founded 1816 by William I., of Holland. In 1820 an old Jesuit college was remodeled for its use. Various other schools have been merged into the university. There are 750 students, over 100 being foreigners. The institution is maintained by the state, which supports a combined library of city and university, containing over 350,000 volumes.

Gherardi, gā-rär'dē, **Bancroft,** American naval officer: b. Jackson, La., 10 Nov. 1832; d. Stratford, Conn., 10 Dec. 1903. He entered the navy in 1846, and was at the Naval Academy in 1852. He was lieutenant on the Lancaster of the Pacific squadron at the commencement of the Civil War, and in 1862 was made lieutenant-commander. During the War he commanded the Chocorua and the Port Royal, being on the latter vessel in the battle of Mobile Bay, in which he was distinguished for bravery and gallantry. He became rear-admiral in 1887; was commandant of the Brooklyn navy yard in 1887; commanded the North Atlantic squadron; and directed the Columbian naval review in New York harbor in 1893. He retired in 1894.

Ghetto, gĕt'ō, **The,** a Jewish quarter in large cities. The ghetto of Rome, instituted in 1556 by Pope Paul IV., was removed in 1885, its demolition having been rendered necessary by the new Tiber embankment. The Ghetto in New York is one of the largest and most densely populated in the world. In a single tenement building are housed as many as 600 persons and a single city block or square contains 3,000 to 5,000 population. The majority of these people are employees of the sweat-shops (q.v.). The population of the New York Ghetto is estimated at 350,000.

Ghibellines, gĭb'ĕ-lĭnz, Italian political party of the 12th to the 15th centuries. On the death of Lothaire II., emperor of Germany, 4 Dec. 1137, Conrad, Duke of Franconia and Lord of Weiblingen (which by corruption became Ghibelline), was elected his successor. His right to the imperial throne was, however, disputed by Henry the Proud, Duke of Saxony and Bavaria, who was in consequence declared an outlaw and shortly afterward died. His adherents transferred their allegiance to his son, Henry the Lion, at that time a boy of 10, and the whole empire was divided into the partisans of Conrad, who assumed the name of Ghibellines, and those of Henry, or the Guelphs. These titles were first used at the battle of Weinsberg in 1140. The strife between the two parties subsided in Germany, but continued in Italy, resulting in war in 1159. The supporters of the popes were termed Guelphs and those of the emperors Ghibellines. Charles of Anjou expelled the Ghibellines from Italy in 1268; but the contest between the two factions continued till the French invasion in 1495 united them against a common enemy.

Ghiberti, Lorenzo, lō-rĕnd'zō gē-bĕr'tē, Italian sculptor: b. Florence about 1378; d. there 1 Dec. 1455. He early learned from his stepfather Bartoluccio, an expert goldsmith, the arts of drawing and modeling, and that of casting metals. He was engaged in painting in fresco at Rimini, in the palace of Prince Pandolfo Malatesta, when the priori of the society of merchants at Florence invited artists to propose models for one of the bronze doors of the baptistry of San Giovanni. The offering up of Isaac was to be executed in gilt bronze, as a specimen of the work. The judges selected the works of Donatello and Ghiberti as the best, but the former voluntarily withdrew his claims, giving the preference to Ghiberti. After 21 years' labor Ghiberti completed the door, and, at the request of the priori, executed a second, after almost as long a period. Michelangelo said of these, that they were worthy of adorning the entrance to paradise. During these 40 years Ghiberti also completed many other important designs, such as the bronze reliquary of St. Zenobius. The dryness of the school of Giotto appears in his early works; the later are in imitation of the Greeks, and are marked by continually increasing vigor and firmness. The reliquary and the baptistery doors of San Giovanni are, to this day, among the finest specimens of art in modern Italy. Ghiberti also executed some excellent paintings on glass for the churches Or-San-Michele and Santa Maria del Fiore. His 'Commentarii,' a work on Florentine art, is still preserved in MS. See Scott, 'Ghiberti and Donatello' (1882).

Ghirlandajo, gēr-län-dä'yō, **Il** (originally **Domenico Bigordi**), Italian painter: b. Florence 1449; d. there 11 Jan. 1494. There were three brothers of this name (Davide, Benedetto, and Domenico) among Italian artists of the 15th century, and Domenico was the greatest of the three. He was thoroughly original and independent in his style and while he lived just after Masaccio and just before Michelangelo, he was distinct from either. He was skilful in portraiture and his large frescoes of religious subjects are historically interesting from the fact that he introduced as spectators of the incidents portrayed the figures of distinguished Florentines of his day. His great fresco of 'The Calling of Peter and Andrew' in the Sistine Chapel at Rome is much admired, and in his 'Last Supper' at Papiguano he has introduced the portrait of Amerigo Vespucci. His finest work is the 'History of St. Francis' in the Church of The Trinity at Florence. He was also a skilful worker in mosaics, which he called "painting for eternity."

He died of the plague in his 45th year and was buried in Sta. Maria Novella, in Florence.

Ghost Dance, a religious ceremony which originated among the Piute Indians in Nevada about 1889, so named from the fact that the dancers wear a white robe over their ordinary dress. It was the outcome of a religious belief which maintained that a messiah was soon to appear, who would rid the land of the white man and restore to the Indians all their rights. A Piute Indian named Wikova and known among the whites as "Jack Wilson," claimed to be this savior and obtained a marvelous influence over not only his own tribes but those of the surrounding country, who sent their chiefs to listen to his teachings. These were very much in the same line as those of modern Spiritualists, he promising to procure them communication with the spirits of deceased friends. He advocated peace and refused to allow any references in their ceremonies to warlike subjects. The ghost dance is held at night, men and women joining hands and circling around, singing the ghost songs, which are principally chants in the form of messages from their spirit friends. Sometimes the participants appear to fall into a trance, during which they are supposed to commune with residents of the other world. The Sioux outbreak of 1890–1 was due indirectly to the ceremonies of this dance and the United States government sought to suppress it. Since that time no trouble has arisen, though it is still practised by the Indians. See INDIANS.

Ghost-moth, a British nocturnal swift-moth (*Hepialus humuli*), so called from the male being white and hovering in the twilight over one spot (often in churchyards), where the female, which has gray posterior wings and red-spotted anterior wings, is concealed. The caterpillar feeds on the hop and allied plants, and often does considerable damage to the first-named. See SWIFT-MOTHS.

Ghosts. The belief that the spirits of the departed are occasionally presented to the sight of the living, has existed in all ages and countries, and usually declines only when a people has advanced considerably in the knowledge of physical conditions and laws. We can understand the inability of the primitive man and the savage to realize death. The memory of the deceased lends power to call up his appearance. The primitive man does not observe accurately the distinction between fact and fancy — between what is seen in dream and what is seen in reality. (See DREAMS.) The belief that man has a soul capable of existing apart from the body it belongs to, and continuing to live, for a time at least, after that body is dead and buried, fits perfectly in such a mind with the fact that the shadowy forms of men and women do appear to others, when the men and women themselves are at a distance, and after they are dead. We call these apparitions dreams or phantasms, according as the person to whom they appear is asleep or awake; and when we hear of their occurrence in ordinary life, set them down as subjective processes of the mind. Among the less civilized races, the separation of subjective and objective impressions, which in this, as in several other matters, makes the most important difference between the educated man and the savage, is much less fully carried out. The Dyaks regard dreams as actual occurrences; and many savage races believe that dreams are incidents which happen to the spirit when it is wandering from the body. In sleep, the soul is supposed to leave the body and travel about. The man who fancies he sees at night the figure of a friend, or of an enemy, supposes he sees this dreamer's wandering soul. Among primitive races there is a superstitious objection to rousing a sleeper, lest he should awake before his soul has had time to return to the body. Death is regarded as another form of sleep; and during that sleep the spirit is wandering, and when wandering, may be met. See SLEEP.

Witchcraft, necromancy, has always been intimately connected with the spirits of the dead, and this is regarded as the parent of all religious worship. The savage man fears the dead and seeks to propitiate them, and gradually forgets that the ghosts are those of ancestors, and considers them as demons, a separate order of spirits; and later, as he advances in intelligence, these demons cease to be altogether demoniacal, and become gods. Be that as it may, it is certain that the propitiation and even worship of the dead has formed an integral part of all primitive religions, and has maintained its hold among the more ignorant after it has ceased to affect the more educated.

The fear of seeing something often so dazzles and bewilders the visual organ, that it sees the things that were feared. This accounts for many stories of the sight of apparitions in haunted houses. A crime is supposed to have been committed in some old house, and superstition believes that the spirit of the murderer or of the murdered person cannot rest. Whoever is nervous and timid, and visits this house at night, is predisposed to see the wandering spirit, and the fear that is present deprives the judgment of its power of taking accurate observations of what really is seen, and so superinduces a lax condition which is ready to be deceived. There may be conditions of body which allow of a sight beyond what is given to most, as it is certain that beasts see and scent and hear what our own faculties fail to perceive. But what we insist on is, that the greatest caution should be exercised in receiving stories of apparitions, and the utmost care taken to investigate every case of apparent spiritual manifestation. Before we can admit that there are genuine cases of ghosts having been seen, we must be satisfied that the observer was in full possession of his faculties, that his attention was on the alert, that he was capable of judging between subjective and objective presentments, and that he was healthy in mind and body.

In 1882 a Society for Psychical Research was founded in London for the scientific and systematic investigation of reported apparitions, clairvoyance, haunted houses, hypnotism, thought-reading, and spiritualistic phenomena; it publishes regular reports of its investigations.

The subject of ghosts is treated from other and various view points under APPARITIONS, and the reader is also referred to SPIRITUALISM and WITCHCRAFT, and the following works: Brewster, 'Natural Magic' (1832); Ingram, 'Haunted Houses' (1884); Myers, 'Phantasms of the Living' (1886); Owen, 'The Debatable Land' (1874); Stead, 'Real Ghost Stories' (1891).

sissippi to England. Finally the struggle of the entire autumn and early winter ended in this treaty, which was scarcely more than an agreement to cease hostilities and settle the disputed questions at some other time. The questions of impressment, on which the war had been opened; of the extent of the right of blockade; of the American right to fish in British waters; of the British navigation of the Mississippi, and trade with the Indians; of the armaments on the Lakes; of the American claim for British spoliations; all were silently passed over. The treaty, as ratified 17 Feb. 1815, and proclaimed on the 18th, restored the *status quo* of territorial possessions except some islands in Passamaquoddy Bay — public or private property in the surrendered places not to be destroyed or removed, provided a commission to decide on the ownership of the islands above, the matter to be referred to arbitration if they failed to agree; and other commissions to settle the boundaries provided in the Treaty of Paris (1783) — from the St. Croix to the St. Lawrence at lat. 45° N., thence to Lake Superior, and from St. Mary's River to the Lake of the Woods. The last article binds both parties to use their best endeavors to suppress the slave trade.

Ghent, University of, Belgium, founded 1816 by William I., of Holland. In 1820 an old Jesuit college was remodeled for its use. Various other schools have been merged into the university. There are 750 students, over 100 being foreigners. The institution is maintained by the state, which supports a combined library of city and university, containing over 350,000 volumes.

Gherardi, gā-rär'dē, **Bancroft,** American naval officer: b. Jackson, La., 10 Nov. 1832; d. Stratford, Conn., 10 Dec. 1903. He entered the navy in 1846, and was at the Naval Academy in 1852. He was lieutenant on the Lancaster of the Pacific squadron at the commencement of the Civil War, and in 1862 was made lieutenant-commander. During the War he commanded the Chocorua and the Port Royal, being on the latter vessel in the battle of Mobile Bay, in which he was distinguished for bravery and gallantry. He became rear-admiral in 1887; was commandant of the Brooklyn navy yard in 1887; commanded the North Atlantic squadron; and directed the Columbian naval review in New York harbor in 1893. He retired in 1894.

Ghetto, gĕt'ō, **The,** a Jewish quarter in large cities. The ghetto of Rome, instituted in 1556 by Pope Paul IV., was removed in 1885, its demolition having been rendered necessary by the new Tiber embankment. The Ghetto in New York is one of the largest and most densely populated in the world. In a single tenement building are housed as many as 600 persons and a single city block or square contains 3,000 to 5,000 population. The majority of these people are employees of the sweat-shops (q.v.). The population of the New York Ghetto is estimated at 350,000.

Ghibellines, gĭb'ĕ-lĭnz, Italian political party of the 12th to the 15th centuries. On the death of Lothaire II., emperor of Germany, 4 Dec. 1137, Conrad, Duke of Franconia and Lord of Weiblingen (which by corruption became Ghibelline), was elected his successor. His right to the imperial throne was, however, disputed by Henry the Proud, Duke of Saxony and Bavaria, who was in consequence declared an outlaw and shortly afterward died. His adherents transferred their allegiance to his son, Henry the Lion, at that time a boy of 10, and the whole empire was divided into the partisans of Conrad, who assumed the name of Ghibellines, and those of Henry, or the Guelphs. These titles were first used at the battle of Weinsberg in 1140. The strife between the two parties subsided in Germany, but continued in Italy, resulting in war in 1159. The supporters of the popes were termed Guelphs and those of the emperors Ghibellines. Charles of Anjou expelled the Ghibellines from Italy in 1268; but the contest between the two factions continued till the French invasion in 1495 united them against a common enemy.

Ghiberti, Lorenzo, lō-rĕnd'zō gē-bĕr'tē, Italian sculptor: b. Florence about 1378; d. there 1 Dec. 1455. He early learned from his stepfather Bartoluccio, an expert goldsmith, the arts of drawing and modeling, and that of casting metals. He was engaged in painting in fresco at Rimini, in the palace of Prince Pandolfo Malatesta, when the priori of the society of merchants at Florence invited artists to propose models for one of the bronze doors of the baptistry of San Giovanni. The offering up of Isaac was to be executed in gilt bronze, as a specimen of the work. The judges selected the works of Donatello and Ghiberti as the best, but the former voluntarily withdrew his claims, giving the preference to Ghiberti. After 21 years' labor Ghiberti completed the door, and, at the request of the priori, executed a second, after almost as long a period. Michelangelo said of these, that they were worthy of adorning the entrance to paradise. During these 40 years Ghiberti also completed many other important designs, such as the bronze reliquary of St. Zenobius. The dryness of the school of Giotto appears in his early works; the later are in imitation of the Greeks, and are marked by continually increasing vigor and firmness. The reliquary and the baptistery doors of San Giovanni are, to this day, among the finest specimens of art in modern Italy. Ghiberti also executed some excellent paintings on glass for the churches Or-San-Michele and Santa Maria del Fiore. His ‹Commentarii,› a work on Florentine art, is still preserved in MS. See Scott, ‹Ghiberti and Donatello› (1882).

Ghirlandajo, gēr-län-dä'yō, **Il** (originally **Domenico Bigordi**), Italian painter: b. Florence 1449; d. there 11 Jan. 1494. There were three brothers of this name (Davide, Benedetto, and Domenico) among Italian artists of the 15th century, and Domenico was the greatest of the three. He was thoroughly original and independent in his style and while he lived just after Masaccio and just before Michelangelo, he was distinct from either. He was skilful in portraiture and his large frescoes of religious subjects are historically interesting from the fact that he introduced as spectators of the incidents portrayed the figures of distinguished Florentines of his day. His great fresco of ‹The Calling of Peter and Andrew› in the Sistine Chapel at Rome is much admired, and in his ‹Last Supper› at Papiguano he has introduced the portrait of Amerigo Vespucci. His finest work is the ‹History of St. Francis› in the Church of The Trinity at Florence. He was also a skilful worker in mosaics, which he called "painting for eternity."

He died of the plague in his 45th year and was buried in Sta. Maria Novella, in Florence.

Ghost Dance, a religious ceremony which originated among the Piute Indians in Nevada about 1889, so named from the fact that the dancers wear a white robe over their ordinary dress. It was the outcome of a religious belief which maintained that a messiah was soon to appear, who would rid the land of the white man and restore to the Indians all their rights. A Piute Indian named Wikova and known among the whites as "Jack Wilson," claimed to be this savior and obtained a marvelous influence over not only his own tribes but those of the surrounding country, who sent their chiefs to listen to his teachings. These were very much in the same line as those of modern Spiritualists, he promising to procure them communication with the spirits of deceased friends. He advocated peace and refused to allow any references in their ceremonies to warlike subjects. The ghost dance is held at night, men and women joining hands and circling around, singing the ghost songs, which are principally chants in the form of messages from their spirit friends. Sometimes the participants appear to fall into a trance, during which they are supposed to commune with residents of the other world. The Sioux outbreak of 1890–1 was due indirectly to the ceremonies of this dance and the United States government sought to suppress it. Since that time no trouble has arisen, though it is still practised by the Indians. See INDIANS.

Ghost-moth, a British nocturnal swift-moth (*Hepialus humuli*), so called from the male being white and hovering in the twilight over one spot (often in churchyards), where the female, which has gray posterior wings and red-spotted anterior wings, is concealed. The caterpillar feeds on the hop and allied plants, and often does considerable damage to the first-named. See SWIFT-MOTHS.

Ghosts. The belief that the spirits of the departed are occasionally presented to the sight of the living, has existed in all ages and countries, and usually declines only when a people has advanced considerably in the knowledge of physical conditions and laws. We can understand the inability of the primitive man and the savage to realize death. The memory of the deceased lends power to call up his appearance. The primitive man does not observe accurately the distinction between fact and fancy — between what is seen in dream and what is seen in reality. (See DREAMS.) The belief that man has a soul capable of existing apart from the body it belongs to, and continuing to live, for a time at least, after that body is dead and buried, fits perfectly in such a mind with the fact that the shadowy forms of men and women do appear to others, when the men and women themselves are at a distance, and after they are dead. We call these apparitions dreams or phantasms, according as the person to whom they appear is asleep or awake; and when we hear of their occurrence in ordinary life, set them down as subjective processes of the mind. Among the less civilized races, the separation of subjective and objective impressions, which in this, as in several other matters, makes the most important difference between the educated man and the savage, is much less fully carried out. The Dyaks regard dreams as actual occurrences; and many savage races believe that dreams are incidents which happen to the spirit when it is wandering from the body. In sleep, the soul is supposed to leave the body and travel about. The man who fancies he sees at night the figure of a friend, or of an enemy, supposes he sees this dreamer's wandering soul. Among primitive races there is a superstitious objection to rousing a sleeper, lest he should awake before his soul has had time to return to the body. Death is regarded as another form of sleep; and during that sleep the spirit is wandering, and when wandering, may be met. See SLEEP.

Witchcraft, necromancy, has always been intimately connected with the spirits of the dead, and this is regarded as the parent of all religious worship. The savage man fears the dead and seeks to propitiate them, and gradually forgets that the ghosts are those of ancestors, and considers them as demons, a separate order of spirits; and later, as he advances in intelligence, these demons cease to be altogether demoniacal, and become gods. Be that as it may, it is certain that the propitiation and even worship of the dead has formed an integral part of all primitive religions, and has maintained its hold among the more ignorant after it has ceased to affect the more educated.

The fear of seeing something often so dazzles and bewilders the visual organ, that it sees the things that were feared. This accounts for many stories of the sight of apparitions in haunted houses. A crime is supposed to have been committed in some old house, and superstition believes that the spirit of the murderer or of the murdered person cannot rest. Whoever is nervous and timid, and visits this house at night, is predisposed to see the wandering spirit, and the fear that is present deprives the judgment of its power of taking accurate observations of what really is seen, and so superinduces a lax condition which is ready to be deceived. There may be conditions of body which allow of a sight beyond what is given to most, as it is certain that beasts see and scent and hear what our own faculties fail to perceive. But what we insist on is, that the greatest caution should be exercised in receiving stories of apparitions, and the utmost care taken to investigate every case of apparent spiritual manifestation. Before we can admit that there are genuine cases of ghosts having been seen, we must be satisfied that the observer was in full possession of his faculties, that his attention was on the alert, that he was capable of judging between subjective and objective presentments, and that he was healthy in mind and body.

In 1882 a Society for Psychical Research was founded in London for the scientific and systematic investigation of reported apparitions, clairvoyance, haunted houses, hypnotism, thought-reading, and spiritualistic phenomena; it publishes regular reports of its investigations.

The subject of ghosts is treated from other and various view points under APPARITIONS, and the reader is also referred to SPIRITUALISM and WITCHCRAFT, and the following works: Brewster, 'Natural Magic' (1832); Ingram, 'Haunted Houses' (1884); Myers, 'Phantasms of the Living' (1886); Owen, 'The Debatable Land' (1874); Stead, 'Real Ghost Stories' (1891).

Ghosts, a powerful play by Henrik Ibsen (1881), giving dramatic embodiment to the modern realization of heredity. Ibsen, treating this subject on its tragic side, considers the case of the darker passions as they are handed down from father to son. It is a Greek tragedy translated into the littleness and barrenness of modern life. 'Ghosts' is perhaps the most remarkable of Ibsen's dramas in its searching judgment, its recognition of terrible fact, its logical following of the merciless logic of nature.

Ghuri, goo'rē, an Asiatic dynasty who had the seat of their empire in the country of Ghur, and ruled over Persia, Afghanistan, northern Hindustan, and Transoxiana. Ghur first appears in history in connection with Mahmud of Ghazni and his son Masaud, the latter of whom subjugated the region in 1020. About a century later Malik Izzuddin made himself ruler of all the Ghur country. His son, Alauddin Jahansoz (the Burner), fell upon Ghazni, and burned it to the ground. This prince's nephews, Ghiyassuddin and Muizuddin, established their power in Khorasan and Ghazni. The latter, crossing the Indus, then conquered successively the provinces of Multan (1176), Lahore (1186), and Ajmere (1190), and, in the course of the next six years all Hindustan as far south as Nagpur and east to the Irawaddy. On the death of Muizzuddin the Indian states asserted their independence, the power of the Ghuri being confined to Ghur, Seistan, and Herât. This last feeble remnant was taken from them by the Shah of Kharezm about 1215. Some 30 years later the Ghur princes managed to revive something of their former power at Herât, which they retained by sufferance from the Mongols down to 1383, when the city was captured by Timur, and the Ghur sovereignty came to an end.

Ghurkas, goor'kaz, **Gurkahs,** or **Goorkhas,** a tribe of northern India, named from the village of Ghurkas in Nepal, formerly the capital of the Ghurkas, before the formation of the present kingdom of Nepal. The Ghurkas are the mountaineers of Nepal, and speak a Sanskritic language. The Mohammedans drove them out of Rajputana, and they migrated to Nepal, of which they took possession in 1768. When the English first invaded India, the Ghurkas were formidable opponents, but are now most friendly. A large number of them are in the Anglo-Indian army, chiefly in the infantry, as they have no regard for the cavalry service. Besides their rifle they carry a formidable short-bent sword called a koorkree, with the edge on the inside of the bend, with which at close quarters they do dreadful execution. See Nepal.

Giacomotti, Félix Henri, fā-lěks ǒn-rē zhä-kō-mō-tē, French artist: b. Quingey, Doubs, 19 Nov. 1828. He was a pupil of Picot at the Beaux-Arts, Paris; obtained the Grand Prix de Rome in 1854; established his studio at Paris in 1861, and painted numerous subjects from mythology, religious works, and portraits. Among his canvases are: 'Centaur and Nymph'; 'Christ Teaching in the Temple'; 'The Mount of Calvary.' He also executed a fresco for the ceiling of one of the salons of the Luxembourg representing the apotheosis of Rubens and painting.

Giant Cells, in pathology, a form of large cells many times the size of the cells of the body with which they are associated. They very frequently have a large number of nuclei, sometimes as many as 100 or more. It is supposed that giant cells originate from a lack of cell-division, rather than by a coalescence of a number of small cells. Many giant cells are found in the neighborhood of active growing tissue, associated with infectious disease processes, such as tuberculosis and carcinoma. It is thought that the function of giant cells is protective.

Giants, people of extraordinary stature. History, both sacred and profane, makes mention of giants. The first mention of giants in the Bible is in Gen. vi. 4, where the Hebrew word used is *nephilim*, a word which occurs in only one other passage, where it is applied to the sons of Anak, who dwelt about Hebron, and who were described by the terrified spies as of such size that compared with them they appeared in their own sight as grasshoppers. A race of giants called the Rephaim is frequently mentioned in the Bible. In Gen. xiv. 5, and xv. 20, they appear as a distinct tribe, holding possessions in Canaan. At the period of the conquest of Canaan, Og, king of Bashan, who had a bedstead 9 cubits long, is said to have remained alone of this tribe, but this must be taken to mean alone on the east side of Jordan; for giants, who were probably of the same stock, are subsequently mentioned as living about Mount Ephraim (Jos. xvii. 15) and among the Philistines (2 Sam. xxi. 18). Goliath, who measured 6 cubits and a span, and who was slain by David, is the most celebrated of the giants mentioned as living among the Philistines. The other races of giants who are mentioned in the Bible (besides the sons of Anak already referred to) are the Emim, who occupied the country afterward held by the Moabites, and the Zuzim (a branch of the Rephaim), who lived on the east side of the Jordan, between the Arnon and the Jabbok. In Deut. ii. 20 they are said to have been called by the Ammonites, who conquered them, Zamzummim.

The giants of Greek mythology are believed by some to represent the struggle of the elements of nature against the gods, that is, against the order of creation. They were said to have sprung from the blood of Uranus, which fell into the lap of Ge (the earth). Their mother, indignant at the banishment of the Titans into Tartarus, excited them to revolt against the gods. They hurled mountains and forests against Olympus, disdaining the lightnings of Zeus. An oracle having declared that the gods could not conquer except by the assistance of a mortal, Athene called Heracles to their aid. He slew Alcyoneus and Porphyrion, the most formidable of the giants. Apollo and Heracles shot out the eyes of Ephialtes; Dionysus slew Eurytus with his thyrsus; Hecate and Hephæstus killed Clytius with clubs of hot iron; Poseidon hurled a part of the island of Cos on Polybotes; Athene buried Enceladus under the island of Sicily, and flayed Pallas, and made a shield of his skin. The remainder perished under the hands of other deities by the thunderbolts of Jupiter or the arrows of Heracles. This fable perhaps indicates volcanic eruptions, for which the Phlegræan fields, where the chief scene of this struggle is placed, and where the two principal giants were born, were remarkable. Cos and Sicily, which figure in this fable, are also volcanic. Ovid has

described the war of the giants in the beginning of his 'Metamorphoses.'

Giants figure rather largely in Celtic and Scandinavian mythology and legends. In the legends of the Irish there are the two giants, Fingall or Finn MacCumhal and his son Ossian. The giants of the Welsh are familiar to every one through the achievements of Jack the Giant Killer, the representative of the Scandinavian Thor, the destroyer of Skrimmer, and the Swiss giants.

The following are regarded as authentic instances of giant stature: In the time of Augustus there were to be seen in the Horti Sallustiani at Rome, the bodies of a giant, Posio, and a giantess, Secundilla, each 10 feet 3 inches high. In the reign of Claudius, an Arabian giant named Gabbaras, 9 feet 4 inches high, was exhibited at Rome. The Emperor Maximin, a Thracian, was nearly 9 feet high. A Jewish giant, about 10 feet high, is mentioned by Josephus. Long Mores, an Irish giant, of the time of Edward III., was 6 feet 10½ inches high. Queen Elizabeth's Flemish porter was 7 feet 0 inches: and J. Middleton, or the Child of Hale, born in 1578, attained the height of 9 feet 3 inches. C. Munster, a yeoman of the guard in Hanover, who died in 1676, was 8 feet 6 inches high; and Cajanus, a Swedish giant, about 9 feet high, exhibited in London in 1742. C. Byrne, who died in 1783, attained the height of 8 feet 4 inches; and Patrick Cotter O'Brien, a native of Kinsale, who lived about the same time, was 8 feet 7¼ inches. In 1884 died Pauline Wedde (called Marian), a German giantess, over 8 feet 2 inches at the age of 18; and in 1887 Josef Winkelmaier, an Austrian, 8 feet 9 inches, aged 22. Anna Swan, a native of Nova Scotia, above 8 feet high; her husband, Capt. Bates, a native of Kentucky, of the same height; Chang-wu-gon, the Chinese giant, 7 feet 9 inches high; and Feodor Machow, a Russian, 7 feet 9 inches, who as late as 1900 were living in retirement, after many years of public exhibition.

Giant's Causeway, Ireland (deriving its name from a legend that it was the commencement of a road to be constructed by giants across the channel to Scotland), a natural pier or mole of columnar basalt, projecting from the north coast of Antrim, Ireland, into the North Channel, 7 miles northeast of Portrush. It is part of an overlying mass of basalt from 300 to 500 feet in thickness, which covers almost the whole county of Antrim, and the eastern part of Londonderry. It is exposed for 300 yards, and exhibits an unequal pavement, formed of the tops of 40,000 vertical closely fitting polygonal columns, which in shape are chiefly hexagonal. The diameter of the pillars varies from 15 to 20 inches. Each pillar is divided into joints of unequal length, the concave hollow at the end of one division fitting exactly into the convex projection of the other. The rock is compact and homogeneous, and is somewhat sonorous when struck with a hammer. The Giant's Causeway is itself formed of three causeways, the Little, Middle or Honeycomb, and the Grand Causeway. On the Little Causeway may be seen an octagon, pentagon, hexagon, and heptagon all together; on the Middle Causeway is the famous Wishing Chair, with two arms and a back, on a platform where the columns rise to a height of about 10 feet. On the Grand Causeway are pointed out the Lady's Fan, an exact arrangement of five perfect pentagons surrounding a heptagon; the Keystone of the Causeway — a sunk octagon; and the single triangle. At the starting point is the Giant's Loom, an imposing row of columns 30 feet high, each intersected by about 30 joints; to the left is the Giant's Well, to the right the Giant's Chair.

Gibara, gē-bä'rä, Cuba, a seaport on the northern coast of Santiago province. It has a fine harbor protected by a fort at the entrance. There is a military hospital here. Pop. 6,841.

Gibbes, Robert Wilson, American scientist and historian: b. Charleston, S. C., 8 July 1809; d. Columbia, S. C., 15 Oct. 1866. He was graduated from South Carolina College in 1827, from the Medical College of South Carolina in 1830. In 1827–35 was assistant professor of chemistry, geology, and mineralogy in the South Carolina College, and in the Civil War was surgeon-general of South Carolina. His contributions to science appeared in the 'Journal' of the Academy of Natural Science, and other learned publications. His paper on 'Typhoid Pneumonia' ('American Journal of Medical Sciences,' 1842) was the first to urge the substitution of stimulants for the knife in the treatment of that disease. He published: 'Documentary History of the American Revolution' (1853 et. seq.).

Gibbet, jĭb'ĕt, a gallows, formerly in use in Europe, on which the bodies of criminals who had been guilty of particularly atrocious crimes were suspended after execution, encased in an iron frame, near the spot where the crime was committed. This was done for the purpose of striking terror into the evil-minded, and of affording "a comfortable sight to the relations and friends of the deceased." The practice, first recognized by law in Great Britain in 1752, was abolished in 1834.

Gibbon, gĭb'ŏn, **Edward,** English historian: b. Putney, Surrey, 27 April 1737; d. London 16 Jan. 1794. He studied at Westminster and Magdalen College, Oxford. At 17 he became a Roman Catholic, but later, at Lausanne, Switzerland, returned to the Protestant faith. In 1758 he returned to England, and soon after composed his 'Essai sur l'Etude de la Littérature' in the French language, which for some years had been more familiar to him than his own. This work, which was printed in 1761, was a highly respectable juvenile performance, and obtained considerable praise in the foreign journals. After passing months in London he then visited Paris and Lausanne, at which latter place he employed himself in collecting and preparing materials for a profitable journey to Italy. This took place in 1764; and it was at Rome, as he himself informs us, on the 15th of October in that year, as he sat musing among the ruins of the capitol, "while the barefooted friars were singing vespers in the Temple of Jupiter," that his idea of writing the 'Decline and Fall of the Roman Empire' entered his mind. In 1774 he obtained a seat in Parliament for the borough of Liskeard, and was a silent supporter of the North administration and its American politics for eight years. In 1776 the first quarto volume of his 'Decline and Fall of the Roman Empire' appeared, and at once riveted general attention, the first edition going off in a few days, and a second and a third being scarcely equal to the

demand. Of all the applause he received none seemed to flatter him so much as the spontaneous suffrages of Hume and Robertson. The progress of his history was for some time delayed by his complying with the request of ministers to answer a manifesto which the French court had issued against Great Britain preparatory to war. This he very ably executed in a 'Mémoire Justificatif,' composed in French, which was delivered in a state paper to the courts of Europe; and for this service he received the appointment of one of the lords of trade (1778). In 1781 appeared the second and third volumes of his history. At a new election he lost his seat for Liskeard, but was brought in for the borough of Lymington. On the retirement of the North administration he lost his appointment by the dissolution of the board of trade, and retired to his favorite Lausanne in 1783. Here, in the course of four years, he completed the three remaining volumes of his history, which were published together in April 1788, on the 51st anniversary of the author's birthday. The storms of the French Revolution, which he regarded from the first with fear and aversion, gradually lessened his attachment to Lausanne, and in 1793 he returned to England. In 1796 his friend Lord Sheffield published two quarto volumes of his miscellaneous works, of which the most valuable part is the 'Memoirs,' written with much apparent frankness. Had he lived, Gibbon would doubtless have completed these memoirs; but as they are the simple, straightforward records of a famous student's labors and aims, who by his manly character made many lasting friendships, they form one of the most interesting, brilliant, and suggestive autobiographies in the English language. Gibbon as a historian has gained enduring fame, and up to the present day the universal acknowledgment of the learned world has allowed him the highest rank. The merits and defects of his great history, its elegance and research, as well as its occasional indecency of allusion and its sneers at revealed religion, are too well known to need comment. A good edition of the 'Decline and Fall' is that edited by Milman (1838–9), with the notes of Guizot. An excellent new annotated edition is that of Bury (seven vols., 1896–1900). In 1897 a selection of Gibbon's private letters was published in two volumes, also 'Autobiographies' in one. See Morrison's 'Gibbon' in English Men of Letters series.

Gibbon, John, American soldier: b. Holmesburg, Pa., 1827; d. 1896. He was graduated from the United States Military Academy in 1847, and after service in the Mexican War was assistant instructor in artillery in the Academy 1854–7 and quartermaster 1856–9. He served in the Civil War and became major-general of volunteers and brevet major-general United States army. In 1891 was retired from the service. He published 'The Artillerists' Manual' (1859).

Gibbon, a tailless anthropoid ape of the East Indies, the several species of which constitute the genus *Hylobates* of the family *Simiidæ*. They are nearly allied to the orangs and chimpanzees, but are smaller, of more slender form, and their arms are so long as almost to reach the ground when the animal assumes an erect posture; there are also naked callosities on the buttocks. In general the gibbons are the lowest among the anthropoid apes, and connect them with the Old World monkeys by way of the semnopithecine group. (See LANGUR.) The gibbons are inhabitants of forests, their long arms enabling them to swing themselves from bough to bough, which they do to wonderful distances and with extreme agility. They cannot, however, move with ease or rapidity on the ground. The conformation of the hinder extremities adds to their difficulty in this, while it increases their adaptation to a life among the branches of trees, the soles of the feet being much turned inward. None of the gibbons are of large size, averaging about three feet tall. Eight or ten species are named in the books, but probably increased knowledge will reduce this number. One, the siamang (*H. syndactylus*) has the second and third digits of the hind limb partly united, and the hair of the upper arm pointing downward, while that on the forearm grows upward. It is a native of Sumatra, and has been set apart as the type of a separate genus (*Siamanga*) by some naturalists. The other species have the digits mostly free; they are natives of Cambodia, the Malay Peninsula, Sumatra, and Java, and are known as lars, hoolocks, agile gibbons, white-handed gibbons, etc., but are much alike. One species is called "wow-wow" in imitation of the howling cry that is characteristic of all. Consult Cassell's and the Royal 'Natural Histories,' and Hartmann's 'Anthropoid Apes' (1886).

Gibbons, Abigail (Hopper), American philanthropist: b. Philadelphia 7 Dec. 1801; d. New York 10 Jan. 1893. She was daughter of Isaac T. Hopper (q.v.) and wife of James Sloan Gibbons (q.v.). She taught in Philadelphia and New York, in 1845 assisted in founding the Women's Prison Association, and was also a founder of the Isaac T. Hopper Home for discharged prisoners. In the Civil War she was active in Federal hospitals and camps. It was chiefly through her instrumentality that the New York State reformatory for women and girls was established by the legislature.

Gibbons, Grinling, English sculptor and wood-carver: b. Rotterdam 4 April 1648; d. London 3 Aug. 1721. In 1671 Evelyn found him at Deptford carving on wood Tintoretto's 'Crucifixion'; and on Evelyn's recommendation he was appointed by Charles II. to a place in the Board of Works, and employed in the ornamental carving of the choir of the chapel at Windsor. His works display great taste and delicacy of finish, and his flowers and foliage have almost the lightness of nature. For the choir of St. Paul's, London, he executed the foliage and festoons, and those in lime-tree which decorate the side aisles. At Chatsworth, at Burleigh, at Southwick, Hampshire, and other mansions of the English nobility, he executed an immense quantity of carved embellishment; the ceiling of a room at Petworth is regarded as his *chef d'œuvre*. He also produced several fine pieces in marble and bronze. Among these are the statue of James II., Whitehall; the base of the statue of Charles I., at Charing Cross; and that of Charles II., at the Royal Exchange.

Gibbons, James, American cardinal: b. Baltimore, Md., 23 July 1834. When very young he was taken by his father to Ireland to be educated. He returned to America in 1853 and re-

HIS EMINENCE JAMES, CARDINAL GIBBONS.

sided in New Orleans until 1855, when he matriculated at St. Charles College, near Ellicott City, Md., where he was graduated with distinction in 1857. He then pursued his theological course at the Seminary of St. Sulpice and at St. Mary's University, Baltimore. On 30 June 1861 he was ordained a priest, his first mission being at St. Patrick's Church, Baltimore, where he was assistant. Transferred to St. Bridget's Church, Canton, he ministered to a small congregation till 1865, when Archbishop Spalding made him chancellor of the archdiocese and his private secretary. The second plenary council at Baltimore, 1866, made him its assistant chancellor, and in August 1868 he was consecrated titular bishop of Adramyttum *in partibus infidelium* and first vicar-apostolic of North Carolina, erected by bull of His Holiness, Pius IX., dated 3 March 1868. He found three churches, two priests, and about 1,000 Roman Catholics scattered over the entire State. He opened a school, which he personally conducted; built six churches; introduced into the vicariate the Benedictine order at Belmont, Gaston County, where Mary Help abbey was later erected; established the Sisters of Mercy and built for them a school for whites and one for negroes in Wilmington. He made the personal acquaintance of every adult Roman Catholic in the State, and met them at their homes, traveling from the seaside to the mountains, up and down the State, that none should be neglected. After four years he was translated to the see of Richmond in 1872. Here he erected five churches, St. Peter's Academy in charge of the Xaverian Brothers, and St. Sophia's home for old people in charge of the Little Sisters of the Poor, in Richmond, Va., and parochial schools in Petersburg and Portsmouth, Va.; and enlarged St. Joseph's female orphan asylum, Richmond, Va. In 1877 Archbishop Bayley asked to have Bishop Gibbons appointed his coadjutor, and on the death of Archbishop Bayley in October of that year Bishop Gibbons became archbishop of Baltimore, the highest ecclesiastical dignitary of the Roman Catholic Church in the United States. He headed the delegation of American prelates who visited Rome in 1883 to represent the affairs of the Church in the United States at the Vatican, and to outline the work of the third plenary council, to meet in 1884. Pope Leo XIII. appointed Archbishop Gibbons to preside over the council. In directing the proceedings of the council he co-operated in the enactment of many important new decrees, made necessary by the progress and development of Catholicism in America; and these acts and decrees were, after mature deliberation, approved by the ecclesiastical authorities. Leo XIII. expressed his approval of the action and course of Archbishop Gibbons and created him cardinal 7 June 1886, and on 30 June 1886 Archbishop Kenrick of St. Louis, representing the Pope, bestowed the insignia of his office upon the newly made cardinal. Cardinal Gibbons sailed for Europe the next year to receive the apostolic benediction and to be admitted to membership in the college of cardinals, the 25th in succession. While in Rome he interpreted to the Pope the democratic spirit of American Catholicism in respect to the labor organizations in the United States and the exact relation existing between the employers and the employed. He was installed as pastor of his titular church 25 March 1887, and was assigned to the Church of Santa Maria in Trastevere, a church of great antiquity, on the Tiber. He returned to America in November 1887; on 24 May 1888 laid the cornerstone of the Catholic University, Washington, D. C., and dedicated the divinity building 13 Nov. 1889. Cardinal Gibbons has been chancellor of the University since its foundation. In November 1888 he celebrated at Baltimore the centenary of the founding of the Catholic hierarchy in the United States, subsequently convening a congress of Catholic laymen, the first ever held in the United States. Cardinal Gibbons is president of the Bureau of Catholic Indian Missions, and is the first American cardinal to take part in the election of a pope. A model Churchman, he is also a typical American citizen, loyal, progressive, and public-spirited. He has published: 'The Faith of Our Fathers' (1876; 58th ed. 1903); 'Our Christian Heritage' (1889); 'The Ambassador of Christ' (1896); etc. The archdiocese of Baltimore now (1905) has a Catholic population of 250,000; 396 priests; 261 churches; 95 parochial schools; 3 universities; 2 diocesan seminaries; 6 hospitals, and other charitable and educational institutions.

Gibbons, James Sloane, American banker: b. Wilmington, Del., 1 July 1810; d. New York 17 Oct. 1892. He early became a strong abolitionist, and in 1863 his house in New York was sacked by a mob, during the draft riots, because he had illuminated it in honor of Abraham Lincoln. His fame rests chiefly on his patriotic song, which was very popular during the Civil War, 'We are Coming, Father Abraham, Three Hundred Thousand More.'

Gibbs, Alfred, American soldier: b. Sunswick, L. I., 22 April 1823; d. Fort Leavenworth, Kan., 26 Dec. 1868. He was graduated from the United States Military Academy in 1846, served in the mounted rifles during the Mexican War, was brevetted captain, and until 1861 was employed in frontier and recruiting service. He served in the Federal army during the Civil War and attained the rank of major-general of volunteers and brevet brigadier-general United States Army. He was mustered out of the volunteer service in 1866, became major of the Seventh cavalry in that year, and until his death was stationed at various Kansas forts.

Gibbs, George, American mineralogist: b. Newport, R. I., 8 Jan. 1782; d. Newtown, N. Y., 5 Aug. 1833. Early becoming interested in the study of mineralogy, he collected during his travels in Europe, chiefly by purchase, a very extensive and valuable cabinet of minerals, the most extensive at the time that had been brought together in the United States. This collection he set up in the public rooms of Yale College, where it remained without charge from 1811–25 and in the latter year it was purchased for the college for $20,000.

Gibbs, James Edward Allen, American inventor: b. 1 Aug. 1829; d. Raphine, Rockbridge County, Va., 25 Nov. 1902. While a young man the subject of the sewing-machine was called to his attention, and presently he thought out the idea of the revolving hook which is the main feature of the Willcox & Gibbs machine. In all he took out 12 patents covering the sewing-

machine. The village in which he resided was named by him when he returned to it in middle life. The name is from the Greek word which means "to sew."

Gibbs, Josiah Willard, American philologist: b. Salem, Mass., 30 April 1790; d. New Haven, Conn., 25 March 1861. He was graduated at Yale College in 1809, and in 1824 was appointed professor of sacred literature in the theological department of Yale College, which he held till his death. He published a translation of Gesenius' 'Hebrew Lexicon of the Old Testament' (1824); 'Manual Hebrew and English Lexicon,' abridged from Gesenius (1828); 'Philological Studies' (1857); 'Latin Analyst' (1858), etc., and contributed to the periodical works of his time numerous important papers on topics of philology and criticism.

Gibbs, Josiah Willard, American mathematician: b. New Haven, Conn., 11 Feb. 1839; d. there 28 April 1903. He was a son of the preceding and was graduated from Yale in 1858. He was professor of mathematics at Yale in 1871 and held the position at the time of his death. Thermodynamics was the field in which he achieved his greatest renown. He was original in his manner of teaching and extremely successful in the class-room. The work that brought him first into prominent notice was his treatise on the 'Equilibrium of Heterogeneous Substances,' published in 1875 by the Connecticut Academy of Arts and Science. His last contribution on this subject was his book in the Bi-Centennial series at Yale, entitled 'An Elementary Treatise on Statistical Mechanics,' wherein he set forth what are likely to be the foundations of this branch of science in the future. In 1881 he began the development of the Vector analysis and applied it to problems in crystallography and to the computation of the orbits of the planets and comets and also to problems in the theory of light. His work gave strong support to the electro-magnetic theory and powerful influence in securing a general adoption of this theory by physicists.

Gibbsite, gĭb'zīt, a mineral usually occurring in mammillary or stalactitic masses or incrustations, or in monoclinic crystals (hydragillite). Its color is usually white, often tinted with green, yellow or red. Its hardness is 2.5 to 3.5 and its specific gravity about 2.4. It is an aluminum hydrate, $Al(OH)_3$, containing 28 per cent of aluminum. It occurs in the Urals, Norway, Brazil and at Richmond, Mass. It was named after George Gibbs (q.v.).

Gibeah, gĭb'ē-ä, the name of several towns in ancient Palestine, the birthplace of Saul, and the scene of Jonathan's romantic exploit against the Philistines.

Gib'el, or **Prussian Carp,** a European carp (*Cyprinus gibelio*) of small size, without barbels and with a forked tail. It occurs in England and is good food.

Gib'eon, one of the ancient cities of the Canaanites, in Palestine, a "great city" of the Hivites, who at an early stage of Joshua's conquests entered into a stratagem to get terms of peace for themselves. Taking old clothes on their persons, and dry and moldy bread in their bags, they professed to have come from a far country, and proposed an alliance with the Israelites, which was accepted by Joshua before the stratagem was discovered. When the discovery was made, the covenant was strictly observed, but the Gibeonites were condemned to be "hewers of wood and drawers of water unto all the congregation" (Jos. ix. 21). The town of Gibeon fell afterward to the lot of Benjamin. It was made a Levitical city, and the Tabernacle was transferred there from Nob after the slaughter of the priests. The engagement between the men of Abner and David took place here. Gibeon has been identified with the modern El-Jib. A large number of the Gibeonites, who had made a covenant with Joshua, were massacred by Saul, for which crime seven of Saul's sons were delivered up by David to the Gibeonites to be hanged (2 Sam. xxi. 1–9).

Gibraltar, jĭ-brâl'tar (Sp. hē-bräl-tär'), a town and strongly fortified rocky peninsula at the southern extremity of Spain, at the western entrance of the Mediterranean, belonging to Great Britain. This remarkable fortress, which lies opposite Ceuta in Africa (distance between Europa Point and Ceuta 14½ miles), and forms the key to the Mediterranean, is connected with the mainland of Spain by a low sandy isthmus, the peninsula having the Bay of Gibraltar on the west, and the open sea of the Mediterranean on the east. The British territory has a length of 2¾ miles and a greatest breadth of ¾ of a mile, the greater part of it consisting of "the rock," at the foot of which, on the north, is a race course, cemetery, etc. The highest point of the rock is about 1,400 feet above sea-level. Its north face is almost perpendicular, while its east side also presents tremendous precipices. On the south it is almost inaccessible, making approach from seaward impossible; the west side, again, although nearly as rugged and precipitous as the others, slopes toward the sea; and here the rock is secured by extensive and powerful batteries, and other works rendering it apparently impregnable. The body of the rock consists of a kind of dense limestone arranged in beds of 30, 40, and 50 feet in thickness. There are a number of remarkable caves in various parts of the rock, but all difficult of access.

Vast sums of money and an immense amount of labor have been spent in fortifying this celebrated stronghold. Numerous caverns and galleries, extending two to three miles in length, and of sufficient width for carriages, have been cut in the solid rock, forming safe and sheltered communications from one part of the garrison to another in cases of attack. Along these galleries are port-holes opening toward the bay or toward the Spanish territory (between which and the British territory there is a strip known as "the neutral ground"); while trees, shrubs, and flowers of various kinds have been planted at different points, both for ornament and utility. On the summit of the rock there are barracks, signal-stations, etc. Of late years the fortifications have been carefully strengthened at every vulnerable point, and guns of the newest construction have been mounted in them. Gibraltar has a naval dockyard, and is a victualing and coaling station of the British navy. Great harbor works have for some time been in course of construction (at a cost of some $20,000,000), including a large area of sea enclosed by massy walls, and graving-docks large enough to accom-

modate the largest battle-ships. The materials have been mostly brought from the east side of the rock by means of a tunnel specially constructed for this purpose.

The town of Gibraltar is situated on the west side of the peninsula, fronting the bay. It consists of two portions, the North Town and the South Town, the former being much the larger and separated from the South Town by the Alameda Gardens, parade ground, etc. The principal buildings are the governor's house, the naval hospital, the civil hospital, the garrison library (45,000 vols.), the court-house, revenue offices, remains of an old Moorish castle, and the barracks. The water for the supply of the town and garrison is collected in tanks during the rainy season. Splendid reservoirs for water have recently been constructed by the government. Gibraltar is a free port, and serves as a valuable entrepôt for the distribution of British manufactures to the neighboring countries. The administration is vested in the governor, who is also commander-in-chief of the troops; and the settlement is treated as a garrison town, the power of enacting laws being vested in the governor alone. All criminal cases are determined according to the laws of England. Newcomers to Gibraltar are stringently looked after. Foreigners are permitted to remain during specified periods only, and on giving the required security. The population in 1901 amounted to 27,460, including a garrison of 5,349 men. The permanent residents are of very various origin — Spanish, Portuguese, Maltese, etc.

The name is formed from the Arabic words *gebel al Tarik* (the height or rock of Tarik), since Tarik Ibn Zeiad, the general of the caliph Valid, at the time of the irruption of the Moors into Spain (711 A. D., and following years), landed at the foot of this rock (known as the *Calpe* of antiquity and one of the *Pillars of Hercules* — Abyla in Africa being the other), where he founded a strong fortress. About the beginning of the 14th century it was taken from the Moors by Ferdinand, king of Castile, but in 1333 it was recovered by them, and was not finally acquired by the Spaniards till 1462, when it was taken in the reign of Henry IV. The Duke of Medina-Sidonia, who had assisted in gaining it for the Christians, took forcible possession of it for himself, and it remained in the keeping of his family till 1501, when the Spanish sovereign got it into his own hands. The third duke unsuccessfully tried to recover it in 1506, by which time the fortress had undergone altogether some half score of sieges. The pirates of Algiers subsequently made an attack upon it, but were forced to retire. The German engineer, Speckel of Strasburg, in the reign of the Emperor Charles V., substituted for the old Moorish fortifications works in the European style. In the war of the Spanish Succession the Spaniards were obliged to surrender this fortress, 4 Aug. 1704, to the British admiral Rooke, assisted by a body of troops under Prince George of Darmstadt. From October 1704 to April 1705 it was besieged by the Spaniards. It was secured to Britain by the Peace of Utrecht in 1713. Since this time nothing has been omitted by Britain to render this fortress, which forms a bulwark of her Mediterranean trade, absolutely impregnable. As the increasing value of the place rendered the possession of Gibraltar more desirable to Spain, the siege of it was commenced 7 March 1727, but raised upon the approach of Admiral Wager, with 11 ships of the line. Spain then offered £2,000,000 sterling for the delivery of the place, but in vain; and by a compact at Seville in 1729 Spain agreed to renounce all its claims upon it. Still the Spaniards omitted nothing to prevent all entrance into the fortress, and to cut it off from the mainland, by constantly strengthening the lines of St. Roch and Algeciras. But it was easy to supply the inhabitants and garrison by sea. In the war which broke out between Britain and Spain in 1779 the last attempt was made for the recovery of Gibraltar. It now underwent the famous four years' siege from 1779 till 1783, but was ably and successfully defended by Gen. Elliot, afterward Lord Heathfield. It was secured to Britain by the Peace of 1783. Since that time, in the various British and Spanish, and also French wars, Gibraltar has only been blockaded on the land side.

Gibraltar of America, Quebec, Canada; so called on account of its commanding situation and its well-nigh impregnable defenses, both natural and artificial. It is the most securely fortified city in America.

Gibraltar of the East, a name given to Aden, a town and seaport of Arabia. Since 1839 it has belonged to the British, and its fortifications have been greatly strengthened and improved. The citadel is built on a rocky eminence, and is of great strategic importance, having a position between Asia and Africa like that of Gibraltar between Europe and Africa.

Gibraltar, Bay of, an inlet of the Atlantic formed by the headland of Cabrita and Europa Point, four miles distant from each other, and is spacious and well adapted for shipping, being protected from all the more dangerous winds; the extreme depth within the bay is 110 fathoms. To increase the security of the harbor, two moles have been constructed, which respectively extend 1,100 and 700 feet into the bay. The Spanish town and port of Algeciras lie on its western side.

Gibraltar, Straits of (anciently called PILLARS OF HERCULES); the straits connecting the Mediterranean Sea with the Atlantic Ocean, extending from Cape Spartel to Cape Ceuta on the northwest coast of Africa, and from Cape Trafalgar to Europa Point on the southwest seaboard of Spain. They narrow toward the east, their width between Europa Point and Cape Ceuta being only 15 miles, while at the west extremity it is 24 miles. Length, about 30 miles. Through these straits a constant current runs so strongly from the Atlantic that sailing vessels bound west can pass them only by the aid of a Levanter, or strong breeze from the east. It is believed that the waters of the Mediterranean find an outlet here by means of an undercurrent.

Gibraltar Ape or **Monkey.** See BARBARY APE.

Gibson, Charles Dana, American illustrator: b. Roxburg, Mass., 14 Sept. 1867. He studied at the Art Students' League (New York), became known as an illustrator for periodicals, particularly for the comic weekly, 'Life,' and through his satirical presentations of wealthy society attained a wide reputation. He has published various collections of his drawings.

Gibson, John, English sculptor: b. near Conway, Wales, 19 July 1790; d. Rome 26 Jan. 1866. He was the son of a landscape gardener, and was apprenticed to a wood-carver at Liverpool, where he attracted attention by a figure of 'Time,' modeled in wax, which he exhibited at the age of 18. The patronage of W. Roscoe (q.v.) assisted him to go to Rome, where he was cordially received by Canova. On the death of Canova in 1822 Gibson entered the studio of Thorwaldsen. In 1836 he was made a royal academician; but to the end of his life continued to make Rome his chief place of residence. Among his best works are: 'The Wounded Amazon'; 'The Hunter and His Dog'; 'Hylas and the Nymphs'; 'Helen'; 'Proserpine'; and 'Sappho.' The subjects of most of Gibson's works are taken from classical mythology, but he was no servile imitator of the antique; on the contrary, he exhibited thorough originality in his treatment, and gave marked individuality and expression to the goddesses, nymphs, and heroines of antiquity that proceeded from his studio. He was the author of one remarkable innovation, at least in modern sculpture, that of coloring his figures, and though he believed to the last that the experiments of this nature which he made were successful, he never succeeded in securing the approbation of other artists for the practice.

Gibson, Randall Lee, American politician: b. Spring Hill, Woodford County, Ky., 10 Sept. 1832; d. Hot Springs, Ark., 15 Dec. 1892. He was graduated from Yale in 1853, studied law in Tulane (then the University of Louisiana) and Berlin, was a sugar planter in Louisiana until the Civil War, entered the Confederate army in the ranks, and finally attained the rank of major-general. Subsequent to the War he practised law, and having entered public life was elected to Congress as a Democrat in 1872, though not seated, was in the House from 1874–82, and in the Senate from 1882 until his death.

Gibson, Robert Atkinson, Protestant Episcopal bishop: b. Petersburg, Va., 9 July 1846. He entered the ministry in 1870, was rector of Moore Memorial Chapel, Richmond, Va., 1872–8; of Trinity Church, Parkersburg, W. Va., 1878–87; and Christ Church, Cincinnati, 1887–97. In November of the year last named he was consecrated coadjutor-bishop of Virginia, succeeding to the bishopric on the death of Bishop Whittle in 1902.

Gibson, Robert Williams, American architect: b. Essex, England, 17 Nov. 1854. He studied at the Royal Academy of Arts, came to the United States in 1881 and has since practised his profession in New York. He has designed many important American buildings, among which are the Episcopal Cathedral at Albany, N. Y., and many churches, the Botanical Museum, New York, and banks at Buffalo, Albany, Utica, and elsewhere.

Gibson, William Hamilton, American artist and author: b. Sandy Hook, Conn., 5 Oct. 1850; d. Washington, Conn., 16 July 1896. Many of his illustrations appeared in the 'Art Journal' and in 'Picturesque America'; and his illustrations of books were numerous and popular. He published: 'Camp Life in the Woods' (1876); 'Pastoral Days' (1881); 'Highways and Byways' (1883); 'Strolls by Starlight and Sunshine' (1891); 'Sharp Eyes' (1896).

Gid, gĭd, or **Staggers,** a disease of sheep caused by a larval tape-worm (*Coenurus*) in the brain. See SHEEP, DISEASES OF.

Giddings, Franklin Henry, American sociologist: b. Sherman, Conn., 23 March 1855. He was graduated from Union College in 1877, and engaged in journalism until 1888, when he became lecturer in political science at Bryn Mawr. In 1894 he became professor of sociology at Columbia University. He has written: 'The Principles of Sociology'; 'The Theory of Socialization'; 'The Elements of Sociology'; 'Democracy and Empire'; and 'Introduction to Sociology.' He has greatly aided in systematizing the facts and theories of his department, and is distinguished from other modern sociologists by the emphasis he lays on the "consciousness of kind" as the distinguishing motive of the social individual, and one of the chief factors in the organization of society.

Giddings, Joshua Reed, American statesman: b. Athens, Pa., 6 Oct. 1795; d. Montreal, P. Q., 27 May 1864. He was admitted to the Ohio bar in 1820; elected a member of its legislature in 1826, and of Congress in 1838, where he was prominent as an opponent of slavery. Not only did he predict the tightening of the slavery chain about the neck of the two parties, but he foresaw the armed struggle. On different occasions in different speeches, he prophesied the Civil War and as a political abolitionist sought to hasten it by using the power of political organization. In 1861 he was appointed consul-general to British North America. Among his works are: 'The Exiles of Florida' (1858); 'The Rebellion: Its Authors and Causes' (1864).

Gid'eon (Heb. Feller, Hewer), deliverer of Israel from the Midianites. These nomad Arabs of the Syrian and Arabian deserts had invaded the central district of Palestine. In one of their expeditions they had murdered Gideon's brothers at Tabor. He is called by an angel of the Lord to save Israel. He is also bidden to destroy the altar of Baal, and to erect a sacrificial altar to Jehovah in its place. He gains from the performance of this command the name of Jerubbaal. Collecting the men of his clan Abieger he surprises the Midianites under cover of night, drives them toward the Jordan and captures and slays the two princes Oreb and Zeb. Continuing his pursuit to the Jordan he overtakes and kills the kings Zeba and Salmunna. The Israelites wished to make Gideon king as a reward for his valor, but he asks merely for the golden earrings taken in the spoil, out of which he makes and sets up an ephod to Jehovah. The victory of Gideon is one of the remarkable events in Jewish history. "The day of Midian" is spoken of in the prophets, and allusions are found to it also in the Psalms, and even in the Book of Revelations.

Giessbach (gēs'bäH) **Falls,** Switzerland, a cataract of the Giessbach, falling into Lake Brienz; consisting of 7 cascades, the largest of which has a fall of 190 feet.

Giffen, SIR **Robert,** English economist: b. Strathaven, Scotland, 22 July 1837. He went to London in 1862, where he was acting editor of

the 'Economist' under Walter Bagehot 1868-76; then founded the 'Statist' and became chief of the Statistical Department in the board of trade and assistant secretary in 1882. He was John Morley's assistant on the 'Fortnightly Review' in 1873–6; and is the author of reports, papers, and essays which have given him a high rank. His works include: 'American Railways as Investments' (1873); 'Stock Exchange Securities' (1877); 'Essays in Finance' (1870); 'The Progress of the Working Classes in the Last Half Century' (1884); 'The Growth of Capital' (1890); 'The Case Against Bimetallism' (1892).

Gifford, Robert Swain, American artist: b. Naushon Island, Mass., 23 Dec. 1840; d. New York 15 Jan. 1905. He studied with Albert Van Beest in Rotterdam, Holland; traveled through California and Oregon in 1869, and in Europe and North America 1870–1. He was best known as a painter of landscapes and seashore scenes, and among noted paintings by him were: 'The Rock of Gibraltar'; 'A Lazy Day in Egypt.'

Gifford, Sandford Robinson, American artist: b. Greenfield, N. Y., 10 July 1823; d. New York 29 Aug. 1880. He was educated at Brown University; studied painting in Europe 1855–7. His works include: 'A Lake Scene on the Catskills'; 'Ruins of the Parthenon'; 'Sunrise on the Matterhorn'; 'Home in the Wilderness'; 'Lake Geneva'; 'Fishing-Boats in the Adriatic'; 'San Giorgio, Venice'; etc.

Gifford, William, English critic: b. Ashburton, Devonshire, April 1757; d. London 31 Dec. 1826. He studied at Oxford, afterward traveled on the continent with Lord Belgrave for some years, and on his return to England devoted his time to literary pursuits. In 1794 he published 'The Baviad,' a poetical satire, in which the poetasters of the Della Crusca school are the chief objects of his ridicule; and in 1795 appeared 'The Mæviad,' a severe animadversion on the degraded state of the drama. These works, though virulent and coarse, display much critical ability. In 1797 he became editor of the Anti-Jacobin newspaper — an office which involved him in a quarrel with Dr. Wolcot, against whom he published a pamphlet in verse, entitled 'An Epistle to Peter Pindar.' His translation of the 'Satires of Juvenal' was published in 1802, and is executed in a manner highly creditable to his abilities. He edited the plays of Massinger, with notes, and a life of that dramatist (1805); and afterward in a similar manner the works of Ben Jonson, Ford, and Shirley. He also translated the 'Satires of Persius.' In 1809 he entered on the editorship of the 'Quarterly Review,' of which he continued to be conductor till 1824, when he resigned. He was interred in Westminster Abbey.

Gift, Theo. See BOULGER, DOROTHY HENRIETTA.

Gigan'tism, a rare form of disease supposed to be associated with changes in the pituitary body; characterized by abnormal processes of growth, chiefly in the bones of the face and extremities. Most giants, as seen in circuses, etc., have this disease or develop it in time. Technically the disease is known as acromegaly (q.v.).

Gigantostraca, jī-găn-tŏs'tra-ka. See EURYPTERUS.

Gignoux, François Regis, frän-swä rā-zhē zhēn-yoo, French painter: b. Lyons 1816; d. Paris 6 Aug. 1882. He studied at the Beaux-Arts and with Delaroche, and in 1840–70 was in the United States, where he became a national academician. Many of his works are in the possession of private collectors of New York. He painted chiefly studies of natural scenery, such as 'The Indian Summer'; 'Niagara by Moonlight'; 'The Bernese Alps at Sunrise.'

Gigoux, Jean, zhŏn zhē-goo, French painter: b. Besançon 8 Jan. 1809; d. 10 Dec. 1894. He studied at the Beaux-Arts, and as a pupil of Géricault and Sigalon, and achieved a high reputation by his historical works, religious and secular, in which he displayed forcible coloring and a faithful attention to detail. By his drawings on the stone, he did much to further the development of lithography. He executed 600 illustrations for an edition of 'Gil Blas.' Among the best of his paintings are: 'The Eve of Austerlitz'; 'The Good Samaritan,' and 'The Death of Leonardo da Vinci,' his chief work now hung in the Besançon Museum. He published: 'Causeries sur les artistes de mon temps' (1885).

Gihon, gī'hŏn, **Albert Leary,** American sanitarian: b. Philadelphia, Pa., 28 Sept. 1833; d. New York 17 Nov. 1901. He was appointed assistant surgeon in the United States navy in 1855; took part in the attack and capture of the barrier forts, near Canton, China, in 1856; and served throughout the Civil War. He was promoted medical director in 1895, and was retired with the rank of commodore the same year. He published: 'Practical Suggestions in Naval Hygiene'; 'Need of Sanitary Reform in Ship Life'; 'Sanitary Commonplaces Applied to the Navy'; 'Prevention of Venereal Diseases by Legislation'; and was editor of 'Annual of the Medical Sciences' for six years.

Gil Blas (zhēl bläs) **of Santillane,** sän-tīl-ăn, **The Adventures of,** a famous romance by Alain René Le Sage. It is a series of pictures of life among all classes and conditions of people in Spain two centuries ago. The narrative runs on, with excursions and interpolated histories, and the thread of the story is as inconsequential as that of a tale of the 'Arabian Nights.' The charm of the work is its absolute truth to human nature, and its boundless humor and satire. These qualities have made it a classic. Le Sage was a Frenchman, who never saw Spain; but through his familiarity with its literature he produced a work so essentially Spanish in its tone and spirit as to provoke long controversy as to its originality. Its writing occupied 20 years; the first two volumes appearing in 1715, and the last in 1735. It has been translated into many languages, the earliest in English; the one which has remained the standard being by Tobias Smollett.

Gila, hē'lä, a river of the United States, an affluent of the Colorado, origin in New Mexico; length 450 miles. Its upper course is through mountains, with many deep and precipitous cañons; farther south it flows through an open and comparatively level country, the valley being productive when irrigated. About 200 miles from the Colorado is the reservation of the Maricopa and Pima Indians. Ancient ruins are numerous on the banks of the Gila.

Gila Monster, the poisonous lizard (*Heloderma suspectum*) of the sandy deserts of the southwestern United States, so called because first brought to notice in the valley of the Gila River, Arizona, and on account of the great size (two feet in length) which it sometimes attains. Another "species" (probably a variety — *H. horridum*) exists in the arid parts of Mexico, where it is called "caltotepon" or crust-lizard. These constitute a family *Helodermatidæ*, characterized by the presence of pleurodont, fang-like teeth, each with a groove on its front and rear surface, and each having near its base a labial gland which secretes venom of the same nature as that of serpents. The food of these lizards consists of worms, centipedes, the eggs of birds and lizards, frogs and other small animals which its bite paralyzes or kills. It is slow to anger, but instances are on record of its biting men, producing illness and in some cases death.

Gilbert, Anne Hartley, American actress: b. Rochdale, England, 21 Oct. 1821; d. Chicago, Ill., 2 Dec. 1904. She was a graceful dancer in early life, and later became very successful in high comedy. She was married to George Henry Gilbert, a dancer, in 1846. She visited the United States in 1846, and in 1849 made her home here. For many years before her retirement she was a member of the Daly Company, her especial roles being those of old women, in which she achieved very marked success. On 21 Oct. 1899, her birthday was observed by her admirers by a special performance, a reception, and the presentation of a silver service at the Lyceum Theatre, New York. Her 'Stage Reminiscences' was published in 1901.

Gilbert, Charles Henry, American educator: b. Rockford, Ill., 5 Dec. 1859. He was graduated at Butler University, Ind., in 1879, and became professor of zoology in the Leland Stanford University in 1891. He is the author of 'Synopsis of the Fishes of North America,' with D. S. Jordan (q.v.).

Gilbert, Grove Karl, American geologist: b. Rochester, N. Y., 6 May 1843. He was graduated from the University of Rochester in 1862 and has been geologist of the United States Geological Survey from 1879. He has published: 'Geology of the Henry Mountains' (1879–82); 'Lake Bonneville' (1890); and numerous reports issued under the direction of the United States government.

Gilbert, Sir **Humphrey,** English navigator: b. Devonshire 1539; d. September 1583. He studied at Eton and Oxford, and adopting the military profession, he served with reputation in France and Ireland. He was knighted in 1570, and sat in the House of Commons as member for Plymouth in the following year. Possessing a strong propensity for speculation and enterprise, he turned his attention to maritime exploration, and published 'A Discourse of a Discovery for a New Passage to Cataia' (1576; reprinted in Hakluyt's collection of voyages, Vol. III.). In 1578 Sir Humphrey Gilbert obtained from the Queen a patent empowering him to discover and colonize in North America any land then unsettled. His first voyage ended in failure, but in 1583 he sailed again with a small fleet, and, having landed on Newfoundland, he took possession of the harbor of St. John's. On his return voyage to England in a small sloop he was lost in a storm. See 'Lives by Tytlor (1833); St. John (1868); Edwards (1868); Payne, 'Voyages of the Elizabethan Seamen' (1880).

Gilbert, Sir **John,** English painter: b. Blackheath, near London, 21 July 1817; d. Villers-sur-Mer, France, 5 Oct. 1897. In 1836 he began to exhibit both in oil and water colors; and in 1852 he was elected an associate, in 1853 a member, in 1871 the president of the Society of Painters in Water Colors, receiving soon after the honor of knighthood. He also became an A.R.A. in 1872, an R.A. in 1876, and a chevalier of the Legion of Honor. His oil paintings include: 'Don Quixote and Sancho Panza'; 'Education of Gil Blas'; 'Murder of Becket'; 'Joan of Arc Entering Orleans'; 'Crusaders'; 'Wolsey at Leicester,' and 'Morning of Agincourt.' He was a well-known and popular illustrator of books.

Gilbert, Linda, American philanthropist: b. Rochester, N. Y., 1847; d. 1895. She became known for her work in the interest of prison reform, and by her success in placing libraries in prisons. She was also foremost in obtaining the incorporation under the laws of New York of the Gilbert Library and Prisoners' Aid Society.

Gilbert, Rufus Henry, American inventor: b. Guilford, N. Y., 26 Jan. 1832; d. New York 10 July 1885. He was graduated at the New York College of Physicians and Surgeons; served as surgeon in the Union army in the Civil War; and was appointed superintendent and medical director of the United States army hospitals. Owing to the failure of his health after the war he abandoned his profession and engaged in the railroad business, making a special study of the needs of rapid transit in New York. The result was the erection of the first elevated railroad in that city.

Gilbert, William, English physician and physicist: b. in 1540 at Colchester, a town in Essex 50 miles from London; d. in 1603, and was buried in Trinity church, Colchester. At the age of 18 he entered Saint John's College, Cambridge, from which he graduated in 1560. In 1564, after taking his M.A. degree, he was appointed mathematical examiner of his college. Later, he devoted himself to the study of medicine, obtaining the Doctorate in 1569 and at the same time a senior fellowship in the University. Leaving Cambridge the same year, he went abroad for four years. In 1601, he was elected President of the Royal College of Physicians, an honor which was followed by his appointment as chief physician to Queen Elizabeth.

Gilbert's fame rests on the discoveries which he made in electricity and magnetism and which he tersely recorded in his work on the magnet, 'De Magnete magneticisque Corporibus,' published in London in 1600. He devoted all the time he could spare from his professional duties during a period of 18 years to the researches described in this remarkable treatise, which researches he informs the "candid reader" cost him over £5,000. By way of distinction, he marks his discoveries with marginal asterisks, large ones denoting important discoveries and small ones, those of minor note. Of the former, there are 21; of the latter 178. Besides a re-

markable title-page, the work contains 84 illustrations.

In magnetism, Gilbert recognizes the magnetic field, the effects of heat, magnetic induction and magnetic screening; but his cardinal discovery is that the earth itself is a great magnet with its magnetic poles, equator and axis. He was led to this generalization by prolonged experiments with globular magnets, or terrellas, on which he poised small magnetic needles, finding that, however placed, they always pointed to the poles. He confirmed his theory by reference to the prevalence of magnetic materials in the crust of the earth, the behavior of the compass-needle and the dip circle, and also by the magnetic condition of vertical masses of iron such as the crosses of church-steeples.

Gilbert was an ardent advocate of the Copernican theory and there is reason to believe that his magnetic work was undertaken in its defence, convinced as he was that the revolution of the earth round the sun and its suspension in space would follow at once from the magnetic attraction of the other planets provided the earth itself could be proved to be a colossal magnet. Gilbert was belittled in *De Augmentis Scientiarum* by Chancellor Bacon, who was a staunch anti-Copernican, but was praised and admired by Galileo and Kepler. Two translations of 'De Magnete' have been made, the first by P. Fleury Mottelay of New York (1893), and the second by the Gilbert Society of London (1900). Gilbert's work stands out as the second landmark on magnetic philosophy, the first being a treatise on the lodestone by Peregrinus (q.v.) A.D. 1269.

BROTHER POTAMIAN,
Professor of Physics in Manhattan College.

Gilbert, William Schwenck, English dramatist: b. London 18 Nov. 1836. He was the son of William Gilbert (1804–89), who published 30 novels, tales, etc. He was a clerk in the Privy Council Office 1857–62, and in 1864 was called to the bar. He contributed to the magazines, and was on the staff of 'Fun,' in whose columns his 'Bab Ballads' first appeared. His burlesque 'Dulcamara' (1866) was followed by other burlesques, dramas, comedies, fairy comedies and operas, chief of which was the celebrated series of Savoy operas written in collaboration with Sir Arthur Sullivan (q.v.) as composer. In nearly all his better-known works Gilbert displays fantastic humor that is often subtle, nearly always healthy in tone, and none the worse for a slight flavor of cynicism. His operas and 'The Bab Ballads' have been exceedingly popular in America. See P. Fitzgerald, 'The Savoy Opera and the Savoyards' (1894).

Gilbert Islands, or **Kingsmill Group,** a group of 15 islands in the South Pacific Ocean, between lat. 1° 0′ S. and 2° 30′ N.; and lon. 172° 0′ and 174° 30′ E. They are the most easterly of the groups collectively constituting Micronesia and are of coral formation, all low, the highest land in the group not exceeding 20 feet. The natives resemble the Malays. The whole group is under the protection of Great Britain, but the islands are self-governed, a sort of republicanism prevailing. Pop. (est.) 40,000.

Gil′bertines, The, a religious order founded about 1141 by Saint Gilbert (1083–1189), a parish priest of Sempringham, Lincolnshire, England. It was the only purely English order ever established prior to the Reformation. At the dissolution of the order, in the reign of Henry VIII., it numbered 22 convents. See Graham, 'Saint Gilbert of Sempringham and the Gilbertines' (1901).

Gilboa, gĭl-bō′a, a chain of hills in Palestine, between 500 and 600 feet high, overhanging the site of the ancient city of Jezreel, and rising between the fertile plain of Esdraelon and the valley of the Jordan. It is memorable as the scene of the defeat and death of King Saul and his three sons at the hands of the Philistines.

Gilchrist, gĭl′krĭst, **William Wallace,** American musician: b. Jersey City, N. J., 1846. He was a pupil of Clarke at the University of Pennsylvania, was an organist in Cincinnati 1872–83, and from that time was in Philadelphia, where he became a member of the faculty of the Musical Academy and a leader of choral societies in eastern States. His setting of Psalm XLVI. for solo voices, chorus, organ, and orchestra obtained the prize for composition at the Cincinnati festival of 1882, and his choral works are well known.

Gilder, gĭl′dėr, **Jeannette Leonard,** American editor: b. Flushing, N. Y., 3 Oct. 1849. Having entered journalism in 1869, she became editorially connected with 'Scribner's Monthly' (the present 'Century Magazine'), was a member of the New York *Herald* staff as literary editor and later musical and dramatic editor (1875–80), and in 1881 with her brother, J. B. Gilder (q.v.), founded and became editor of the 'Critic,' a monthly review of literature, drama, and art. Her publications are: 'Taken by Siege' (1886–96); and 'The Autobiography of a Tomboy' (1900). She also dramatized Sienkiewicz's 'Quo Vadis.'

Gilder, Joseph B., American journalist: b. Flushing, N. Y., 29 June 1858. After varied experience in journalism he, with his sister, J. L. Gilder (q.v.), established the 'Critic,' of which he became an editor. In 1895 he was appointed literary adviser to the Century Company and subsequently London representative of Dodd, Mead & Company. He edited 'Orations and After-Dinner Speeches of C. M. Depew' (1890), and other publications.

Gilder, Richard Watson, American editor and poet: b. Bordentown, N. J., 8 Feb. 1844. After secondary schooling he was a private of artillery during the emergency campaign in Pennsylvania (1863), and later managing editor of the Newark (N. J.) *Advertiser.* He subsequently established, with Newton Crane, the Newark *Register,* was editor of 'Hours at Home,' a monthly of New York, and when this was merged in 'Scribner's Monthly' became managing editor of the latter (1870). In 1881 he succeeded J. G. Holland (q.v.) as editor-in-chief of the 'Monthly,' in which capacity he remained after it became the present 'Century Magazine.' He was prominently identified with public affairs as chairman of the New York Tenement-house Commission (1894), member of the council of the National Civil Service Reform League, and other posts, and was a founder of the Authors' Club, the International Copyright League, and the Society of American Artists. The best of his verse, most of which originally appeared in magazines, was collected in 'Five Books of Song' (1894). Later volumes

are: 'In Palestine, and Other Poems' (1898), and 'Poems and Inscriptions' (1901).

Gilder, William Henry, American journalist and arctic explorer: b. Philadelphia 16 Aug. 1838; d. 1900. He served in the Civil War, and was brevetted a major at its close. He accompanied Lieut. Schwatka in 1878 on a polar expedition, and in 1881 was a member of the Rodgers expedition as a correspondent of the New York *Herald*. His chief works are: 'Schwatka's Search' (1881); 'Ice Pack and Tundra' (1883). He was a brother of R. W. Gilder (q.v.).

Gil'dersleeve, Basil Lanneau, American classical scholar: b. Charleston, S. C., 23 Oct. 1831. He was graduated at Princeton in 1849, and studied in Germany for several years. He was professor of Greek and Latin at the University of Virginia from 1856 to 1876, when he was appointed professor of Greek at Johns Hopkins University. He is the founder and editor of the 'American Journal of Philology.' Among his works are: 'Satires of Persius Flaccus' (1875); 'Justin Martyr' (1875); 'Odes of Pindar'; 'Latin Grammar' (1867); 'Essays and Studies' (1890); 'Greek Syntax' (1900).

Gilding, the art of applying and permanently attaching gold leaf or gold dust to surfaces of wood, stone, metals, etc. The Egyptian monuments present numerous traces of the existence of the art in ancient Egypt. The process seems to have been the same with that now used. The Persians also were acquainted with this art, as appears from the ruins of Persepolis. The Greeks and Romans employed gilding for many purposes. The Greeks used to gild the hoofs and horns of victims. The practice of gilding statues prevailed in the infancy of the art of sculpture, and was never entirely dropped by the ancients. The Romans used to gild sweetmeats; and many articles of furniture and utensils which have come down to us are gilt. There are also specimens of gilt glass and metals. The gilding which still remains on some ancient bronze monuments is remarkable for its brilliancy. The ancients carried the practice of gilding to a greater extent than the moderns; they gilded almost all their statues of bronze, wood, or plaster, and frequently those of marble, the ceilings of rooms, and even marble columns. The most remarkable examples of gilding employed with taste and effect in architecture, are the ceiling of St. Peter's, and that of Santa Maria Maggiore.

The art of gilding at the present day is performed on metals, or on wood, plaster, leather, parchment, paper, glass, etc. Chemical processes are those which are usually employed for metals. Gilding on copper is performed by the process called wash or water gilding, with an amalgam of gold and mercury. The surface of the copper, being freed from oxide, is covered with the amalgam, and afterward exposed to heat till the mercury is driven off, leaving a thin coat of gold. Copper, however, is rather too soft and dark-colored a metal to be treated in this way with advantage. Brass is a very suitable metal for this mode of gilding, but the best of all is a mixture of copper with one seventh of brass. The following method of gilding articles of copper, brass, etc., was patented by Elkington in 1836: Five ounces troy of fine gold are dissolved by heat in a mixture of 21 ounces of pure nitric acid of specific gravity 1.45, 17 ounces of pure hydrochloric acid of specific gravity 1.15, and 14 ounces of distilled water. The liquid is then poured off into a stone vessel, the sediment being left at the bottom of the vessel in which it was first contained. Four gallons of distilled water and 20 pounds of the best bicarbonate of potash are now added and the whole is boiled moderately for two hours. At the end of this time the mixture is ready for use. The articles are gilded by being attached to wires and plunged into the mixture, where they are allowed to remain as long as the workman thinks necessary, from a few seconds to a minute, when the mixture is newly prepared, but longer if it has been used for some time. Gilding is also performed by dipping a linen rag in a saturated solution of gold, and burning it to tinder. The black powder thus obtained is rubbed on the metal to be gilded with a cork dipped in salt water till the gilding appears. Iron or steel is gilded by applying gold leaf to the metal, after the surface has been well cleaned and heated till it has acquired the blue color, which at a certain temperature it assumes. Several leaves of gold are thus applied in succession, and the last is burnished down cold. The same process may be applied to copper. The operation of gilding may also be performed on iron and steel by diluting the solution of gold in nitro-hydrochloric acid with alcohol and applying it to the clean surface. A saturated solution of gold in nitro-hydrochloric acid, being mixed with three times its weight of sulphuric ether, dissolves the chloride of gold and the solution is separated from the acid beneath. To gild the steel it is merely necessary to dip it, the surface being previously well polished and cleaned, in the ethereal solution for an instant, and on withdrawing it to wash it instantly by agitation in water.

Gilding on wood, plaster, leather, parchment, or paper, is performed by different processes of mechanical gilding. The first of these is oil gilding, in which gold leaf is cemented to the work by means of oil size. In the case of paper or vellum the parts to be gilded receive a coat of gum water or fine size, and the gold leaf is applied before the parts are dry. They are afterward burnished with agate. Lettering and other gilding on bound books are applied without size. The gold leaf is laid on the leather and imprinted with hot brass types. Brass rollers with thin edges are employed in the same way for lines, and similar tools for other ornaments. When the edges of the leaves of books are to be gilded they are first cut smooth in the press, after which a solution of isinglass in spirits is laid on, and the gold leaf is applied when the edges are in a proper state of dryness. Japanner's gilding is another kind of mechanical gilding which is performed in the same way as oil gilding, except that instead of gold leaf a gold dust or powder is employed.

Porcelain and other kinds of earthen-ware as well as glass may be gilded by fixing a layer of gold in a powdered state by the action of fire. The gold dust or powder required in this operation may be obtained by precipitating it from a solution in aqua regia, either by means of sulphate of iron or protonitrate of mercury. In order that the gold powder may be applied to the surface of the article to be gilded it must be

well mixed with some viscous vehicle such as spirits of turpentine mixed with some fatty matter, or strongly gummed water. It is then laid on with a fine camel's hair brush. When the article to be gilded is made of soft porcelain, delft-ware, or any kind of earthen-ware with a plumbiferous glazing, nothing else is required than to apply the gold in this manner, and then subject the piece of earthen-ware to a heat sufficient to soften the glazing, and thus fix the gilding. But in the case of hard porcelain, some kinds of stoneware and other varieties of pottery, in which the glazing does not soften at a suitable temperature, the gold powder, before being mixed with the viscous vehicle by which it is applied, must have a flux added to it, which serves as a means of attachment between the metal and the earthen-ware. The best flux is oxide of bismuth precipitated by water from a solution of nitric acid, with the addition of one twelfth part of melted borax. One tenth or one fifteenth part of this flux is added for every part of gold contained in the mixture, which is applied to the surface of the earthen-ware. Heat is applied in the same way as in the previous case to melt the flux, and thus fix the layer of gold to the article. The gilding must finally be burnished in order to bring up the gold color. Another method of gilding these substances is to mix neutral chloride of platinum with rectified spirits of turpentine in such a manner that the chloride is held in suspension in a finely divided state in the turpentine, to apply this liquid to the article to be gilded by means of a brush, and then to subject the article to heat so as to volatilize the spirits of turpentine and leave a uniform layer of platinum affixed to the glass or earthen-ware. The article, after being cooled, cleaned with aqua fortis, and washed with water, is next dipped in a gilding liquid prepared like that already described as patented by Elkington. The gilding is completed by rubbing the gilt parts with chamois leather. This method of gilding has the advantage of enabling the gilder to dispense with the burnishing, which is a very hazardous operation for fragile articles, and in the case of those which are of a very intricate form or very deeply cut out often impracticable. See METALLURGY.

Gilead, gĭl'e-ad (rough, rugged, hard), a country on the east side of the Jordan, at one time a portion of the kingdom of Israel. Its exact area is doubtful; but the southern boundary, the River Arnon, and the western boundary, the Jordan River, are well defined. The Yarmuk is given by some as a northern boundary; and some historians mention the country of Gilead as extending to the shores of the Sea of Galilee and the Plains of Bashan. The eastern boundary was "the desert." It is a mountainous country traversed by many small streams which flow into the Jordan. All the mountains are mentioned frequently as "mountains of Gilead," and one peak is called in ancient history, "Mount of Gilead." This peak is thought to be the one now known as Jebel or Djabal (mount) Osha. The soil is fertile and the vegetation generally luxuriant. The low round mountains or hills are no hindrance to cultivation as practised by the native inhabitants. A considerable portion is devoted to pasturage and large herds of cattle and flocks of sheep graze on the hillsides and table-lands as in the times mentioned in the Old Testament. The balm of Gilead, a small evergreen tree of the *Terebinthine* family, has long been noted because of the efficacy of its balm (balm of Mecca) in healing wounds. The terebinth tree and the oak still flourish in Gilead, especially in the valley of the Jabbok. Gilead is mentioned frequently in the Bible. Much of its history before the birth of Christ is given in the Old Testament. In Deuteronomy and Numbers may be found an account of the conquest of the country and the transfer of a part to Reuben and Gad. In Judges and Kings is a record of the wars waged upon Gilead by the Syrians, the Midianites, and the Ammonites, and finally the victory of the Assyrians. The flight of Absalom is given in 2 Sam. xiii. In 1 Sam. xxi. is an account of the battle in which the sons of Saul were slain, and of Saul's own death. It is there told that "the valiant men of Jabesh-Gilead arose and went all night, and took the body of Saul and the bodies of his sons from the wall of Beth-Shan," and burned them according to the custom of the times. And afterward these "valiant men" fasted several days. The chief cities of Gilead were Jazer, Mizpeh, Mahanaim, Penuel, and Succoth.

Giles, jīlz, **Saint (Saint Aegidius),** a native of Greece, who, according to legend, lived in the 7th century. He gave all his property to the poor, and went to France, where he lived in solitude for many years. Finally he permitted companions in his retreat, and founded a house of the Benedictine order. A town grew up around it, and was called Saint Giles. The saint is the patron of many churches in France, Germany, Scotland, and Poland.

Giles, Saint (Saint Giles in the Fields), a parish in London, a mile to the northwest of St. Paul's. The church is in classical style, and contains the remains of Chapman, Shirley, Marvell, Lord Herbert of Cherbury, and Sir Roger L'Estrange. One district of it, by its poverty and wretchedness, long formed a very striking contrast to the west end of the metropolis, so that Saint Giles and Saint James were spoken of as typical of wretchedness and luxury respectively. There is another London church of Saint Giles, called Saint Giles Cripplegate, which contains the tomb of Milton.

Giles, William Branch, American politician: b. Amelia County, Va., 12 Aug. 1762; d. Albemarle County, Va., 4 Dec. 1830. He was educated at Hampden-Sidney College and at Princeton, studied law and practised at Petersburg, was a member of the Federal House of Representatives in 1790–8 and 1801–2, and of the Senate in 1804–15. In 1827–30 he was governor of Virginia. Originally a Federalist, he later became a Republican, and was the leader of his party in the Senate 1804–11. He took a prominent part in the Virginia Constitutional convention of 1829–30. He was an effective speaker, assertive in methods and frequently broke with his party, in which he finally lost influence. His 'Political Letters to the People of Virginia' appeared in 1813.

Gilgal, gĭl'găl, the name of several ancient towns near the Jordan, where the Israelites passed the river into Caanan, where they were circumcised and held the first Passover after leaving the desert (Joshua iv. 10). Here rested the tabernacle, till removed to Shiloh; here

Samuel held court as judge of Israel, and here Saul was crowned. It is frequently mentioned in the Bible; a school of the prophets was established here (2 Kings iv. 38), yet it afterward became a seat of heathen worship (Amos iv. 4). Josephus places one of the towns within two miles of Jericho, but no traces of it are at this day extant.

Gill, gĭl, Sir **David,** Scottish astronomer: b. Aberdeen 12 June 1843. He was chief of staff of Lord Lindsay's observatory, founded in 1870; in charge of Lindsay's expedition to Mauritius in 1874 to observe the transit of Venus and the opposition of Juno, by means of the heliometer, for the determination of the solar parallax. He determined the longitudes of Malta, Alexandria, Suez, Aden, Bombay, Seychelles, Reunion, Mauritius, and Rodriguez by cable and chronometers, and measured the first base-line for the Egyptian triangulation at the request of the khedive. In 1877 he was in charge of the expedition to Ascension to observe the opposition of Mars for parallax; and in 1879 appointed director of the Cape Observatory. He has published many valuable professional papers and reports.

Gill, Henry Z., American physician: b. Richboro, Pa., 6 Oct. 1831. He was a surgeon in the Union army during the Civil War; and was professor of chemical and operative surgery in Wooster University 1883–6; removing to Kansas in the year last named. His publications include: ‹Report on the Prisons of the United States›; ‹Gill's Sanné on Diphtheria, Croup, and Tracheotomy›; etc.

Gill, Theodore Nicholas, American educator: b. New York 21 March 1837. He became professor of zoology in Columbian University in 1884. His publications include: ‹Arrangement of the Families of Mollusks›; ‹Arrangement of the Families of Mammals›; ‹Catalogue of the Fishes of the East Coast of North America›; and ‹Scientific and Popular Views of Nature Contrasted› (1882); ‹Principles of Geography› (1884); etc.

Gill Net, a net suspended vertically, by means of floats, and leaden weights, in standing or running water, fresh or salt. It has meshes which allow the head of the fish to pass, but are too small for the body beyond the gills to get through, and when the captive tries to draw back, catch in the gills, from which no effort can disentangle them.

Gil'lem, Alvan Cullem, American soldier: b. Jackson County, Tenn., 1830; d. near Nashville, Tenn., 2 Dec. 1875. He was graduated from the United States Military Academy in 1851, served in the Seminole war (1851–2), in the Civil War became brevet colonel, United States Army, and brigadier-general of volunteers, and upon the reorganization of the State government of Tennessee was vice-president of the convention for revision of the Constitution and a member of the first legislature of the new régime. In 1867–8 he commanded the district of Mississippi. He attained the rank of colonel and brevet major-general in the regular service.

Gillenia, jĭ-lē'nĭ-a, or **Proteranthus,** a North American perennial genus of *Rosaceæ,* closely allied to *Spiræa,* embracing only two known species; also called Indian physic, bowman's root, and American ipecac. See Bowman's Root.

Gillespie, gĭ-lĕs'pĭ, **Eliza Maria,** American philanthropist: b. near West Brownsville, Washington County, Pa., 21 Feb. 1824; d. Notre Dame, Ind., 4 March 1887. In 1853 she became a member of the congregation of the Holy Cross, and after a novitiate in France was appointed in 1855 superior of the St. Mary's Academy, Bertrand, Mich. She later transferred the academy to its present location, St. Mary's, Ind., and established nearly 30 similar institutions in the United States. During the Civil War she directed from Cairo, Ill., an important hospital work for Federal soldiers. Upon the separation of the congregation of the Holy Cross in the United States from the order in Europe she was for two terms superior.

Gillespie, George de Normandie, American Protestant Episcopal bishop: b. Goshen, N. Y., 15 June 1819. He was graduated from the General Theological Seminary in New York in 1840, entered the ministry and held rectorates at Leroy, N. Y.; Cincinnati, Ohio; Palmyra, N. Y., and Ann Arbor, Mich. In 1875 he was consecrated bishop of Western Michigan. He published ‹The Communion of Saints› and other religious works.

Gillette, William, American actor and playwright: b. Hartford, Conn., 24 July 1853. He studied at the University of Boston, and at New York University; and in 1877 commenced his work on the stage, playing with different stock companies in New Orleans, Boston, New York, and other cities. He has since then acted important parts in many of his own plays. Among his best-known productions are: ‹The Professor› (1881); ‹Esmeralda› (1881), with Mrs. F. H. Burnett; ‹The Private Secretary›; ‹Held by the Enemy› (1886); ‹A Legal Wreck› (1888); ‹Too Much Johnson› (1895); Secret Service› (1896); and ‹Sherlock Holmes.›

Gillis, gĭl'ĭs, **James Melvin,** American astronomer: b. Georgetown, D. C., 6 Sept. 1811; d. Washington, D. C., 9 Feb. 1865. He entered the navy in 1827, soon obtained leave of absence and was graduated at the University of Virginia, and then spent six months in study in Paris. He was in charge of the observation of occultations and transit observations made in connection with the Wilkes exploring expedition, Gillis making the observations at the Washington end at a little observatory on Capitol Hill. He had charge of the United States astronomical expedition to the southern hemisphere, and in 1861 was appointed superintendent of the national observatory at Washington, D. C. He published: ‹Astronomical Observations› (1846); ‹Report of the United States Astronomical Expedition of 1849–52› (1855).

Gillis Land, an arctic region north of Spitzbergen, first sighted in 1707 by Gillis, a Dutchman, in lat. 81° 30′ N. and lon. 36° E., but not visited by him. Some geographers identify it with King Charles or Wiche Land, one of the Spitzbergen group.

Gill'man, gĭl'man, **Henry,** American botanist: b. Kinsale, Ireland, 16 Nov. 1833. He settled in Detroit, Mich., in 1850; and was United States consul at Jerusalem in 1886–91. During his consulate he so strongly opposed the Turkish

DANIEL COIT GILMAN,

PRESIDENT CARNEGIE INSTITUTION.

government in its expulsion of Jews from Palestine that several European countries supported him, and the exclusion laws were modified. He is the author of 'The Wild Flowers and Gardens of Jerusalem and Palestine' (1894); 'Hassan' (1896); etc.

Gillmore, gĭl'môr, **Quincy Adams**, American military officer: b. Black River, Lorain County, Ohio, 28 Feb. 1825; d. Brooklyn, N. Y., 7 April 1888. He was graduated at West Point in 1849; promoted captain in 1861, and brigadier-general of volunteers in 1862. He displayed skill as an engineer by the capture of Fort Pulaski in April 1862, and was appointed commander of the Department of the South in June 1863. He made a successful attack on Morris Island in July 1863, began to bombard Fort Sumter and Charleston in August, and took Fort Wagner in September; Fort Sumter was reduced to a ruinous condition, but its garrison continued to hold it till 17 Feb. 1865. Gen. Gillmore commanded the Tenth corps near Richmond in 1864, and was brevetted major-general, United States Army, in 1865.

Gillott, jĭl'ŏt, **Joseph**, English manufacturer: b. Sheffield 11 Oct. 1799; d. Birmingham 6 Jan. 1872. He shares with Sir Josiah Mason the credit of having brought the manufacture of steel pens to its present state of high perfection.

Gills, gĭlz, the breathing organs of fishes, larval amphibians, crustaceans, and certain other aquatic animals. See *Respiratory System*, in article ANATOMY; also FISH.

Gillyflower, jĭl'ĭ-flow-ėr, a popular English name for some of the cruciferous plants most prized for the beauty and fragrance of their flowers, as the wallflowers and stocks; also for *Hesperis matronalis*, dame's rocket or dame's violet (q.v.). The name gillyflower has been regarded as a corruption of July-flower; but in Chaucer it appears in the form *gilofre;* and the French *giroflée* indicates the true derivation from *girofle*, a clove, the smell of the clove-gillyflower, or clove-pink, having suggested the name of that flower.

Gilman, gĭl'man, **Arthur**, American educator and author: b. Alton, Ill., 22 June 1837. He was engaged in banking in New York 1857–62, when he removed to Lenox, Mass., and devoted himself to literary and educational work until he went to Cambridge in 1870. He was the originator (1876) of the Harvard Annex, of which he became executive officer, and, upon its organization as Radcliffe College, regent. In 1886 he founded and became director of the Cambridge school for girls, known as the Gilman School. He edited Chaucer's works (1879) and other collections, collaborated in several volumes of the 'Stories of the Nations' series, and wrote a number of educational works, chiefly historical in character, such as 'The Story of Rome' (1886); 'The Colonization of America' (1887).

Gilman, Caroline Howard, American author: b. Boston 8 Oct. 1704; d. Washington, D. C., 15 Sept. 1888. In 1819 she was married to the Rev. Samuel Gilman (q.v.) and removed with him to Charleston, S. C., where she began to edit in 1832 the 'Rosebud,' a juvenile weekly newspaper, which subsequently took the name of the 'Southern Rose,' and contained articles of much literary merit. From this periodical she reprinted at different times the 'Recollections of a New England Housekeeper' ([illegible]); 'Recollections of a Southern Matron' (1836); 'Ruth Raymond, or Love's Progress'; 'Poetry of Traveling in the United States'; 'Verses of a Lifetime'; 'Mrs. Gilman's Gift Book'; and other volumes. The first two of these works attracted particular attention by their practical lessons as well as their genial simplicity and humor, and passed through many editions. She was especially successful, also, in her books for children.

Gilman, Charlotte Perkins Stetson, American writer: b. Hartford, Conn., 1860. She is a daughter of Frederic Beecher (q.v.) and was married to G. H. Gilman in 1900. She is a prominent advocate of equality for women and has published 'Woman and Economics' (1898); 'In This Our World,' a book of verse (1898); 'The Yellow Wall Paper' (1899); 'Concerning Children' (1900).

Gilman, Daniel Coit, American educator: b. Norwich, Conn., 6 July 1831. He was graduated at Yale College in 1852; was professor of physical and political geography in Yale in 1856-72; and president of the University of California 1872–5. When Johns Hopkins University was founded in Baltimore, Md., in 1875, he was elected its first president and served in that capacity till 1901, when he resigned. In 1896–7 he was a member of the commission to settle the boundary line between Venezuela and British Guiana, and in the latter year also served on the commission to draft a new charter for Baltimore. He was president of the American Oriental Society 1893–1901, and has been vice-president of the Archæological Institute of America, executive officer of the Maryland Geological Survey, and president of the National Civil Service Reform League in 1901. His publications include: 'Life of James Monroe' (1883); 'University Problems' (1898); Introduction to DeTocqueville's 'Democracy in America'; 'Life of James D. Dana'; etc. On the organization of Carnegie Institution, Washington, D. C., 29 Jan. 1902, he was elected president, and in 1893 president of the American Bible Society.

Gilman, John Taylor, American statesman: b. Exeter, N. H., 19 Dec. 1759; d. there 31 Aug. 1828. In 1775, on the morning after the news of the battle at Lexington and Concord reached Exeter, he marched with 100 other volunteers to Cambridge, Mass., where he served in the provincial army. In 1782 and 1783 he was a member of the Continental Congress, and in 1797 he was chosen governor of New Hampshire, and was annually re-elected for 10 successive years. In 1813–14–15 he was again elected governor, after which he declined to be a candidate. He was a zealous Federalist, and his popularity in New Hampshire was so great that he was frequently chosen governor when his party was in the minority.

Gilman, Nicholas, American statesman: b. Exeter, N. H., 3 Aug. 1755; d. Philadelphia 2 May 1814. He was a brother of J. T. Gilman (q.v.) and like him served in the Continental army during the War of the Revolution. He represented New Hampshire in Congress in 1786, and again 1789–97, and was a United States Senator 1805–14. He was one of the

framers of the Constitution of the United States.

Gilmer, Jeremy Francis, American soldier: b. Guilford County, N. C., 23 Feb. 1818; d. 1 Dec. 1883. He was graduated at West Point and entered the engineer corps of the United States in 1839. At the opening of the Civil War he resigned his captain's commission and entered the Confederate service, becoming major-general in 1863.

Gilmor, gĭl'môr, **Harry,** American soldier: b. Baltimore County, Md., 24 Jan. 1838; d. Baltimore 4 March 1883. He entered the Confederate army at the beginning of the Civil War, became known for his exploits as scout, in 1863 raised a battalion of horse of which he was made major, and later in that year, in command of the 1st Maryland Confederate regiment, captured Frederick, Md., and Chambersburg, Carlisle, and Gettysburg, Pa. In 1864 he led Early's advance into Maryland. He was elected Baltimore's police commissioner in 1874, and wrote 'Four Years in the Saddle' (1866).

Gilmore, gĭl'mōr, **James Roberts** («Edmund Kirke»), American miscellaneous prose writer: b. Boston, Mass., 10 Sept. 1823. He was at first in mercantile life, subsequently entering journalism and literature, and his earlier works were written under the pseudonym, «Edmund Kirke.» He wrote: 'Among the Pines' (1862); 'My Southern Friends' (1862); 'Down in Tennessee' (1863); 'Life of Garfield'; 'Among the Guerrillas'; 'Adrift in Dixie' (1863); 'On the Border'; 'Patriot Boys'; 'The Rear-Guard of the Revolution'; 'John Sevier as a Commonwealth Builder'; 'The Advance-Guard of Western Civilization' (1888); etc.

Gilmore, Joseph Albree, American politician: b. Weston, Vt., 10 June 1811; d. Concord, N. H., 17 April 1867. He became superintendent of various New Hampshire railway lines, was elected to the State Senate in 1858, and re-elected in 1859. In 1863 he was elected governor by the legislature, and in 1864 re-elected by popular vote. His energy increased the troops furnished by New Hampshire to the Federal armies from 15,500 to 33,258.

Gilmore, Patrick Sarsfield, American musical conductor: b. near Dublin, Ireland, 25 Dec. 1829; d. St. Louis, Mo., 24 Sept. 1892. He went to Boston at 18 and the next year organized Gilmore's band. In 1869 he arranged the Peace Jubilee in Boston, and in 1872 the World's Jubilee, in Boston also. Later he formed the noted 22d Regiment band in New York, which gave concerts in the United States and made a European concert tour in 1882. He composed but little; an anthem entitled 'Columbia,' intended to serve as the country's national hymn, was his only work of note.

Gilmour, gĭl'moor, **Richard,** American Roman Catholic prelate: b. Glasgow, Scotland, 28 Sept. 1824; d. St. Augustine, Fla., 13 April 1891. He was ordained priest in 1852, and after various pastorates, including those at Portsmouth, Ironton, Cincinnati, and Dayton, was consecrated bishop of Cleveland in 1872. His administration of the diocese was markedly efficient, and particularly so along the lines of Roman Catholic education. He published a Bible history, a series of 'Catholic National Readers,' and other books, and in 1874 founded the 'Catholic Universe,' an influential journal.

Gilolo, jē-lō'lō, **Jilolo,** or **Halmahera,** an island of the Molucca group in the Indian Archipelago, belonging to the Netherlands; area 6,500 square miles; length 225 miles. It is of singular form, consisting of four peninsulas, radiating from a common centre, and having large bays between. It is rugged and mountainous, the mountains being volcanic. The original inhabitants have been gradually pressed into the interior by the Malays. Pop. 120,000.

Gilpin, gĭl'pĭn, **Henry Dilwood,** American lawyer: b. Lancaster, England, 14 April 1801; d. Philadelphia 29 Jan. 1860. He was graduated from the University of Pennsylvania, studied law and became State attorney in 1822. He was United States attorney for Pennsylvania in 1832, and attorney-general of the United States 1840–1. Besides 'Reports of Cases' he published 'Opinions of the Attorney-Generals of the United States from the Beginning of the Government to 1841' (1841) and edited 'The Papers of James Madison' (1846).

Gilpin, John, the hero of a well known ballad by William Cowper, entitled 'The Diverting History of John Gilpin, Showing how he Went Further than he Intended and Came Safe Home Again.' It was first printed anonymously in 1782, and published with the author's name in 1785.

Gilsonite, gil'sōn-īt, also called **Uintahite,** a natural hydrocarbon compound; a pure hard variety of asphaltum. It is very brittle, a lustrous black in color and fuses. It is used for a great variety of purposes in the arts, for instance in the manufacture of varnishes. Mixed with heavy California maltha or with petroleum residuum it has been used as a paving cement. The principal deposits in the United States are near Soldiers' Summit in Uintah County, Utah. The total output in 1902 was 4,052 short tons, valued at $61,182.

Gilthead, or **Gilteye,** English names for a small and beautiful sea-bream (*Chrysophrys aurata*), with conspicuous gold-colored spots over the eyes. It abounds in the Mediterranean, and ranges northward to England and southward to the Cape of Good Hope. This was one of the fishes kept and fattened by the Romans in their vivaria. Several other species are known in the Far East, one species (*C. berda*), being one of the favorite fishes of Madras under the name of black rock-cod.

Gin (more properly Geneva, from Fr. *genièvre,* «juniper»), a compounded spirit, prepared by redistilling plain spirit with juniper berries, coriander seeds, angelica root, etc., or by adding various essential oils to rectified spirit. The gin produced by distilling possesses a much more delicate flavor than that produced by mixing or compounding. The strength of gin varies from proof to 50 under proof. It was first made in Holland, notably at Schiedam.

As used in machinery the word gin is an abbreviation of engine and is used of Whitney's device for separating cotton-seed from the fibre and more generally of a portable hoisting machine whose frame is a tripod, one leg being movable so as to vary its angle of elevation, and thus determine the height of the apex. The other two legs preserve their relative distance

and form standards for the drum, round which the rope is wound by power applied to the handspikes. For heavy weights a fall and tackle is used; and for hoisting a bucket from a well or mine, simply a couple of pulleys to change the direction of motion of the rope. One pulley is suspended from the apex, and the other attached between the two permanent legs, so as to change the rope to a horizontal position, for the attachment of a draught horse.

Gin, Cotton. See COTTON; COTTON GIN.

Ginatilan, hē-nä-tē'län, Philippines, a town on the western coast of Cebu, at the mouth of the Rio Ginatilan. There is valuable timber in the vicinity. Pop. (1900) 12,144.

Ginevra, gĭ-nev'ra, or jē-nĕv'ra, the title of a noted narrative poem by Samuel Rogers. It is named for its heroine whose affecting story is also recounted in 'The Mistletoe Bough,' a ballad by Thomas Haynes Bayly.

Gingal. See JINGAL.

Ginger, in botany, *Zingiber officinale*, common or narrow-leaved ginger, and in ordinary language the rhizomes of the same plant, which has subsessile linear lanceolate smooth leaves, oblong spikes, acute bracts, and a three-lobed lip. It is a native of India, but is cultivated in most tropical countries. A broad-leaved ginger, *Z. zerumbet*, also a native of India, is used externally for cataplasms and fomentations, but is not eaten. The pieces or races of the rootstocks are usually from 2 to 4 inches long, branched, flat, and of a pale buff color. Ginger is known in commerce under two forms, coated and uncoated or scraped; the latter is deprived of its epidermis when in the green state, and sold as white ginger. The chief varieties imported into the United States are Jamaica, Cochin, Bengal, Japan, and African. The first three are scraped gingers, and of these Jamaica is the most esteemed owing to its color and flavor. Ginger is an agreeable aromatic, and a valuable stomachic; but is more largely used as a condiment than as a medicine. Preserved ginger, imported from China in jars, consists of the young rhizomes boiled in syrup. Ground ginger is frequently adulterated with sago flour, wheat flour, ground rice, and arrowroot.

Ginger Ale or **Beer,** an effervescent drink, made of ginger, water, sugar, cream of tartar (or lemon juice), etc. A well-known method is by pouring a gallon of boiling water over ¾ pound of loaf-sugar, 1½ ounces of sliced ginger, and the peel of one lemon, and after allowing the mixture to cool till it is milk-warm adding the juice of a lemon and a spoonful of yeast.

Gingerbread Tree. See DOOM PALM.

Ging'ham (*ali, gingamo*, from Guingamp, a town in Brittany, where the fabric was woven), a kind of cotton, the manufacture of which was introduced into Great Britain through France from India. It is distinguished from calico by having the colors woven in with the fabric, not printed on it. The patterns are various; sometimes fancy designs, sometimes checkered, and sometimes striped.

Gingili (jĭn'jĭ-lĭ) **Oil,** a name often given to the bland fixed oil obtained by expression from the seeds of *Sesamum Indicum*. It is used medicinally as laxative or mild purgative. See SESAME.

Ging'ko, the Japanese name of a genus of trees (*Salisburia*), of the yew group of conifers. The *S. adiantifolia* (*Gingko biloba* of Linnæus), the only species, is a tree which sometimes attains a height of nearly 100 feet. Its head is conical, and the branches are usually horizontal. The leaves are compound, with from two to four thick coriaceous leaflets marked with small longitudinal nervures, their resemblance to the maidenhair fern giving it its English name of maidenhair tree. It is a native of China and Japan, and was first introduced into Europe in 1754. Its fruit, which is of the size of a small plum, has a pulp with a disagreeable odor of butyric acid and enclosing a kernel which, when roasted, may be used as food, having a taste like that of maize. It is largely eaten throughout China and Japan. The Japanese consider the tree sacred and plant it near their temples. The gingko is considerably used as an ornamental tree in England and in the United States. It flourishes best in the shade, in a deep and somewhat moist soil.

Ginigaran, hē-nē-gä'rän, Philippines, a pueblo of the province of Negros Occidental, at the mouth of the Ginigaran River on the east shore of Guimarás Strait, 29 miles south of Bacólod; it is also on the West Coast road. Pop. 13,620.

Ginseng, jĭn'sĕng, several species of herbs of the genus *Panax*, natural order *Araliaceæ*. The most noted species are *Panax ginseng*, a native of China, and *P. quinquefolium*, of America. These two species so closely resemble each other that the discovery of the latter near Montreal, Quebec, in 1716, was based upon a description of the former. The plants grow about 18 inches tall, bear five long-petioled nearly smooth leaves arising from one point, whence also arises the flower-stem bearing an umbel of small flowers from which develop conspicuous scarlet, generally two-seeded berries. The light yellow root, especially of the former species, is used by the Chinese for every conceivable domestic and medicinal use and specimens resembling the human body often command their weight in gold because of supposed occult virtues. Neither species, however, is considered by American or British physicians to have any pronounced medical qualities. The Asiatic species has long been cultivated in China and Korea.

Shortly after the discovery of the American species a shipment of the wild root was made to China and soon a trade was established. Since the plant has a natural range from the valley of the St. Lawrence to the mountains of Georgia and westward to the eastern bank of the Mississippi, the wild supply of roots long met the demand. In 1858 the price was 52 cents a pound; in 1902, $5.55, the advance being largely due to the decrease of the native supply. In the latter year many lots of northern root (considered always better than southern) sold for $8.00 or even more. The advancing price led to many attempts to cultivate the plant, but until about 1885 none were reported successful. Then George Stanton, of Apulia, N. Y., succeeded by growing the plant in beds prepared in the forest and later under lath sheds. These methods have led to the establishment of American ginseng growing. Cultivated ginseng has commanded about 20 per cent more than wild root from the same locality.

The plants thrive best in a well-drained, rather loose soil, well supplied with humus, potash and phosphoric acid, but not with nitrogenous material. Little has been done to improve the plant, but the time required to mature a crop of roots can probably be shortened considerably and the size of the root increased. In 1902 most growers calculated upon five years as necessary to mature a crop, but at the price of $2.50 a pound they figured upon making a profit under reasonably favorable conditions. The atrocious prices paid for plants and seed during 1898–1903 were largely due to speculation, an exaggerated estimate of the demand in China, which is almost the sole market, and to the novelty of the industry, and hence the scarcity of plants and seed. Consult: Revised edition of Bulletin No. 16, Division of Botany, United States Department of Agriculture (Washington, D. C.); Kains, 'Ginseng' (New York 1902).

Ginx's (gĭnks'ĕz) **Baby,** the title of a famous book by John Edward Jenkins. It is a satire on the English poor-laws and the administration of sectarian charitable associations, and was published anonymously in London in 1871. It speedily ran through many editions, was republished in the United States, and excited warm controversy in the press and even in parliament. It was followed by satires on other phases of social economy, but none of the other works of this author attained such a vogue or exerted such an undoubted influence upon the direction of social reforms.

Giobertine (jō-bĕrt'ĭn) **Tincture,** a preparation for restoring writings which have become illegible through age, or faded pictures. The inventor of it was Giovanni Antonio Gioberti, a native of Piedmont (1761–1834). This invention has been invaluable in restoring the original writing of palimpsests. See PALIMPSEST.

Gioja, jō'yä, **Flavio,** Italian mariner: **b.** Pasitano, near Amalfi, in the latter part of the 13th century. He is said to be the inventor of the mariner's compass, of which he made use in 1302–3. The tendency of the loadstone to turn toward the north was known before his day, but the compass then in use consisted only of a magnetized reed floating upon cork in a vessel of water. Gioja invented the plan of suspending it on a pivot, thus leaving it free to move in any direction, whereby observations were rendered both easier and more exact.

Giorgione, jŏr-jō'nĕ (easel name of GIORGIO BARBARELLI or BARBARELLA), Italian painter: b. Castelfranco 1477; d. Venice 1511. He was a pupil of Giovanni Bellino, and painted history and portraits. He was one of the most celebrated of the Venetian school, was a fellow student of Titian, whom he might have rivaled, had he not died of the plague in early life, while Titian lived for nearly a century. To him Venetian painting owes much of its marvelous technique, and by his example in the use of pigments and glazings he set an example many followed; he has had more pictures by other hands attributed to him (nearly a hundred) than any other Italian master. Even connoisseurs have been deceived by the depth and richness of coloring, the luminosity of aërial perspective, which his imitators had learned from him too well. Yet there are not more than 12 authentic pictures by Giorgione, and these are dispersed among the public galleries of Florence, London, Madrid, Dresden and Vienna.

Giotto, jŏt'tō (called GIOTTO DI BONDONE), Italian painter and architect: b. Vespignano, near Florence, about 1266; d. Florence 8 Jan. 1337. He was the son of a peasant, and was employed, it is said, in tending cattle. But having been once seen by Cimabue, as he was drawing figures of his sheep upon a piece of slate with a stone, that artist obtained leave from his father to take him with him, carried him to Florence, and taught him painting. This may be a mere story, but at any rate his first teacher was Cimabue. His natural talent, and especially the gracefulness so peculiar to him, developed so rapidly that he soon surpassed all contemporary artists. He represented the human figure in his pieces with truth and nature, and excelled in the dignity of his figures, a pleasing arrangement of them, and a regard to correct proportions and natural disposition of the drapery. His earliest extant works are mural paintings in the Church of St. Francis at Assisi, executed before the end of the 13th century. He was now called to Rome, and after painting various works there he went to Padua, in 1303, and adorned the chapel of the Annunciata dell' Arena with a series of famous frescoes, including 38 subjects, disposed in three rows, on the sides of the chapel and the front of the chancel wall, with a vast representation of the 'Last Judgment' filling the west end. Dante was his guest at Padua in 1306, and he is celebrated in the great poet's 'Divina Commedia.' He was also a friend of Petrarch. He worked also at Milan, Verona, Ravenna, Rimini, and Arezzo. In 1330–33 he was at Naples, and in 1334 was appointed master of the cathedral works and other undertakings at Florence, where he designed the celebrated Campanile, a structure finished by his scholar and godson, Taddeo Gaddi. Besides the frescoes at Assisi and Padua, comparatively few works of Giotto are extant. Among his most celebrated pieces is the 'Navicella' (ship) at Rome (a picture of 'Peter Walking upon the Waves,' in mosaic). The National Gallery possesses a 'Coronation of the Virgin' painted in tempera, on wood. "The influence of Giotto was profoundly felt over the greater part of Italy. His example caused a revolution in art, the effects of which are traceable into the 15th century." Many anecdotes of more or less authenticity are told regarding this painter. On one occasion, when asked for a sample of his art to show the Pope, Giotto is said to have drawn a perfect circle with a single stroke; whence "round as the O of Giotto" became proverbial. See Crowe and Cavalcaselle, 'History of Painting in Italy' (1864–6); Janitscheck, 'Die Kunstlehre Dantes und Giottos Kunst' (1892); Ruskin, 'Giotto, and his Works in Padua' (1854–60); Zimmermann, 'Giotto' (1899); Thiorle, 'Giotto' (1902).

Gippsland, gĭps'lănd, Australia, one of the four important districts into which Victoria is divided, so named after an early governor. It forms the southeast portion of Victoria, and has an area of 13,898 square miles. Its length from west to east is 250 miles, and mean breadth about 80. It was originally called Caledonia Australis by Macmillan, its first explorer (1839).

Gipsies, jĭp'sĭz (from Egyptians, the name by which they were called in the English stat-

utes), a wandering nation. They are called by the French Bohémiens, from the belief that they were Hussites driven from their country; in Switzerland, the Netherlands, and the Black Forest they go under the names of Heiden (Pagans); in North Germany, Denmark, and Sweden they are called Tater (Tartars). The name they most frequently pass under in Germany is Zigeuner, which is not unlike the Italian Zingaro or Zingano, the Spanish Zingaro or Gitano, the Hungarian Cigany, the Turkish Tschinganeh. They call themselves Rom, whence Romani, or Romany, the name of their language. The number of gipsies in Europe is roughly set at perhaps 750,000. Of this number about 200,000 are in Rumania; 95,000 in Austria-Hungary; 120,000 in European Turkey; 40,000 in Spain; 40,000 spread over Germany, France, and Italy; 18,000 in Great Britain; and the remainder scattered over other countries. The main body of their language is the same throughout Europe, and even now has a close affinity with the dialects of Hindustan, though it is mixed with a great number of words and expressions borrowed from the races among whom they have sojourned. The gipsies are distinct from the people among whom they dwell, especially in their bodily appearance as a race and in their language. They are slight and agile in frame, though sometimes tall of stature. Their skin is tawny, or olive-colored, their eyes large, dark and brilliant. They have long hair, raven-black, and sometimes ringletted. The mouth of the gipsy is small and finely shaped, and the teeth of pearly whiteness. Scientific men have come to the conclusion that these wanderers are neither of European nor of African origin, but are a remnant of some obscure Indian tribe. This ethnological conclusion is borne out by the fact that their language is undoubtedly derived from the Sanskrit, although intermingled with Oriental terms and inflections appear words of Greek, Slavic, Rumanian, Magyar, German, French, and English origin.

Their history is curious and interesting. Organized gipsy bands first appeared in Europe at the beginning of the 15th century, and in Italy their number in 1422 was computed at 14,000. Five years later they made their first appearance in Paris, saying that they were Christians of Lower Egypt, driven to take refuge in Europe from the Saracens, and had recently left Bohemia. They professed to be performing a penance imposed upon them by Pope Martin V., who, after hearing their confessions of sins committed during their travels, had ordered them to wander over the earth for seven years without taking rest on beds. They were permitted to settle outside the city of Paris, but when they began to practise palmistry and fortune-telling the archbishop had them driven away, and excommunicated the vast number of citizens who had consulted them. Other bands succeeded the 120 gipsies who first made their appearance in Paris: these latter had crossed the channel for England. They were great thieves and in every European country they visited were regarded with disfavor. In vain laws were passed against them. Francis I. of France ordered them to leave the country on pain of being sent to the galleys without trial. The States-General of Orleans condemned them to perpetual banishment. In the middle of the 15th century Pope Pius II. cites them as thieves from the Caucasus. In 1492 Spain exiled them and renewed the decree 100 years later. Elizabeth of England followed Henry VIII. in uttering a proclamation against them. In Scotland they were sheltered and protected, and John Faw, Lord and Earl of Little Egypt, was empowered by royal writ to exercise authority over his gipsy subjects. Germany tried to eliminate them, and Maria Theresa in 1768 undertook to settle them as peasants on the land. This attempt was not successful, but Joseph II., by severe measures induced many of them to settle, practise trades, and have their children educated. Though their number in Europe must be estimated at three quarters of a million they are less a vagrant class than formerly, a fact which is due largely to the stricter policing of the rural districts, and the increase of intelligence among the peasantry, and among the gipsies themselves. Gipsies have never settled in the United States as vagrant communities.

Gipsy-moth, a large moth (*Porthetria*, or *Ocneria, dispar*), of the family *Liparidæ*, imported into Massachusetts, in 1868, where it soon became a pest by defoliating shade-trees: and up to 1900 it had cost the commonwealth $1,550,000. The sexes of the moth differ greatly, the male expanding only about one and a half to two inches, while the female measures across its expanded wings two and a half inches; the female is spotted brownish, and the male is white, marked with black lines. The former lays her eggs in masses to the number of 500 wherever convenient, covering them with hairs and scales from her own body. The females have such heavy abdomens that the wings are inadequate for flight, hence the insect, owing to the measures which have been employed to prevent its artificial carriage has not spread far beyond the place where originally introduced, near Malden. The caterpillar measures when mature about 1.5 inches, is white, with black markings, and furnished with long hairs. It is arboreal and capable of being most troublesome on shade, forest, and fruit-trees, but when abundant it feeds and develops on any form of vegetation. A single generation is produced annually. The best means of combating it are spraying with arsenical mixtures, the collection of the cocoons and egg-masses and destroying them: the scraping of loose bark from trees, thus destroying the young and depriving them of hiding places; also the destruction of the eggs by means of oily substances, and the trapping of the larvæ with strips of burlap placed about the infested trees. Consult: 'The Gipsy Moth,' by Forbush & Fernald (Boston 1896); Howard, 'The Gipsy Moth in America,' Department of Agriculture, (Washington, 1897).

Giraffe, jĭ-răf', or **Camelopard**, the tallest of mammals (*Giraffa camelopardalis*), the type of a family of ruminants (*Giraffidæ*), intermediate between deer and antelopes, and also containing the okapi (q.v.). It is a native of Africa south of the Sahara, but is now to be found only in the interior, remote from civilization and where there are brushy plains or open forest, and is fast decreasing. It occurs generally in small herds of from 5 to 40. It feeds on the leaves and small branches of trees, especially mimosas, which, in districts where the animals abound are kept cropped to a convenient height

for browsing. Its general aspect is remarkable from the height of the foreparts and great elongation of the neck, the head being sometimes 18 feet from the ground. The number of vertebræ in the neck, however (seven), is not greater than in other quadrupeds, and it has no extraordinary flexibility, although its form and movements are very graceful. The length, therefore, is due to the elongation of each cervical vertebra. The body is short, and the back slopes from the shoulder to the tail; yet the greater height of the foreparts is not entirely owing to the greater length of the fore-legs, but to the neural processes of the vertebræ, which form a basis for the support of the neck and head. The head is long, capable of a wide range of movements, and the upper lip is projecting and somewhat prehensile, while the tongue is remarkably capable of elongation, and can be thrust far out of the mouth, and employed to grasp and take up even very small objects; it is said that its tip can be so tapered as to enter the ring of a very small key. The usefulness of such an organ for drawing in leaves and branchlets to the mouth is obvious. The giraffe adroitly picks off the leaves of acacias and other thorny plants, without taking the thorns into its mouth. The dentition of the giraffe agrees with that of antelopes, sheep, and oxen; the upper jaw of the male is destitute of the canine teeth which are present in the male of many deer.

Anatomically the most remarkable feature of the giraffe is the presence in both sexes of two protuberances between the ears, generally described as horns, but very different from the horns of other animals, and each consisting of a permanent bone united to the skull by an obvious suture, covered with skin and hair, and terminated by long hard bristles. These long outgrowths correspond to the bony core of the antelope's horn or to the pedicel of the antler in the deer. There is also a projection on the forehead, which, in the giraffes of South Africa, is so elongated as to indicate a separate species (*G. australis*) in the opinion of recent naturalists. If this view be accepted then the name *camelopardalis* applies properly only to the giraffes now to be found only in Somaliland. Moreover, Sir H. Johnston has reported that there exists in Uganda a very brilliantly colored form which has five horny protuberances, instead of three, upon the head; and when better known may prove to be in a new genus as well as of a novel species. The hair of the giraffe is short and smooth, with a short mane on the neck, and a tuft on the end of the tail. The color is reddish-brown in irregular areas sharply marked off by white borders, like the mortar between brick-work; but there is much variation in tint as well as pattern. A few extinct forms are found fossil in the Pliocene beds of China, India, and Greece, of which *Samotherium* and *Hallidotherium* are prominent examples; they had a shorter neck and legs and more bovine appearance than their successors, and the males alone have horns.

The giraffe is an inoffensive animal, and generally seeks safety, if possible, in flight, although it is capable of making a stout resistance, and is said to beat off the lion by kicking with its hind-legs, discharging a storm of kicks with extraordinary rapidity. It is not easily overtaken even by a fleet horse, and has greatly the advantage of a horse on uneven and broken ground. Its pace is described as an amble, the legs of the same side moving at the same time. The giraffe was known to the ancients, and was exhibited in Roman spectacles. Representations of it appear among Egyptian antiquities. It has been supposed to be the zemer of the Jews, translated chamois in the English Bible (Deut. xiv. 5).

It is one of the costliest and most uncommon animals in menageries, although in former years they were kept and bred in Europe. The flesh is excellent meat, and the hide is thick and makes good leather. Consult: Beddard, 'Mammalia' (1902), and the writings of naturalists and sportsmen in Africa, especially Johnston, Baker, Bryden, Holub, and Selous.

Giralda, hē-räl'dä (Spanish *girar,* "to turn round"), a weathercock in the form of a figure or statue. It is pre-eminently applied to the weathercock, and from that to the Moorish tower or minaret (part of the cathedral) which it surmounts at Seville, Spain. The figure in this weathercock is that of Faith, which turns round to face every wind and storm. In the copy of the tower of Seville cathedral which appears in Madison Square Garden, N. Y., the figure of Faith is replaced by that of Diana.

Girard, jĭ-rärd', **Charles,** American naturalist: b. Mülhausen, France, 1822. In 1839 he was a pupil of Agassiz, at Neufchâtel, Switzerland, and soon became one of his assistants, accompanying him to America, and remaining his assistant until 1850. He was attached to the Smithsonian Institution 1850–9, and has published: 'Herpetology of the United States Exploring Expedition under Capt. Wilkes' (1858); and many professional articles and monographs.

Girard, zhē-rär, **Marc Amable,** Canadian politician: b. Varennes, P. Q., 25 April 1822; d. Winnipeg 10 Sept. 1892. In 1871 he was admitted to the bar of Manitoba, in whose politics he was long active as treasurer (1870–2), premier (1874), and later secretary, minister of agriculture, and president of the council. In 1871 he became a senator of the Dominion of Canada and in 1872 a member of the executive council for the Northwest Territories.

Girard, Philippe Henri de, fē-lēp ŏṅ-rē dē, French inventor: b. Lourmarin, France, 1 Feb. 1775; d. Paris 26 Aug. 1845. He was a man of versatile, scientific tastes, but concentrated his powers on mechanics. When Napoleon offered 1,000,000 francs as a prize for a machine that would spin flax, Girard invented the machine, but the fall of Napoleon deprived him of the reward. In 1815 he settled in Austria, built a flax-mill at Hirtenberg, and inaugurated steamboat service on the Danube. At the invitation of the Russian czar he went to Poland in 1825 and established a flax-mill which became the centre of the village of Girardou.

Girard, jĭ-rärd', **Stephen,** American philanthropist: b. Bordeaux, France, 24 May 1750; d. Philadelphia 26 Dec. 1831. In 1769 he settled in Philadelphia and engaged in various trades. Later, in 1780–90, he formed a partnership with his brother John and for some years continued a most successful West Indian and coastwise trade. He became interested in the first United States Bank in Philadelphia, and in 1812 had

purchased the controlling interest and building. The bank continued to do business under the name of the Girard Bank, and soon became one of the foremost financial institutions of the country. He was a man of peculiar habits, ill-tempered and repellent in manner, but with all, a man uncommonly generous in his charities, chief among which was the $5,000,000 left for the erection and maintenance of a college for male white orphans. During the rage of yellow fever in Philadelphia he was ever present in relieving the afflicted, both by his free giving and by his personal care.

Girard, Kan., a city and county-seat of Crawford County, on the Atchison, T. & S. F., and St. Louis & S. F. R.R.'s. Its situation is well adapted to agricultural pursuits. It has 6 churches, 2 banks, and 3 public schools. The industries include zinc smelting, stove manufacturing, and flour-mills. The city owns its own water-works. Pop. (1900) 2,473.

Girard College, Philadelphia, Pa., an institution for the education of poor white orphan boys; founded under the will of Stephen Girard, and opened 1 Jan. 1848. By a provision in the will no ecclesiastic, missionary, or minister of any sect whatever is to have any connection with the college. At the close of the school year 1900 it reported: Professors and instructors, 67; students, 1,731; volumes in the library, 16,800; productive funds, $15,938,293; income, $1,000,000; number of graduates, 4,754; president, A. H. Fetterolf, Ph.D., LL.D. The total value of the college property exceeds $16,000,000.

Girardin, MADAME **Delphine Gayde,** dĕl-fēn gād zhē-rär-dăṅ, French poet and novelist: b. Aix-la-Chapelle, Rhine Province, Prussia, 26 Jan. 1804; d. Paris 29 June 1855. Carefully educated by her mother, Sophie Gay (q.v.), she won fame with her poetry at the age of 15, an academic prize at 18, and a royal pension at 20. In 1831 she married the eminent journalist M. Emile de Girardin, and began now to turn her attention to prose fiction, producing successively: 'Le Lorgnon'; 'Le Marquis de Pontanges'; 'La Canne de M. de Balzac'; 'Il ne faut pas jouer avec Douleur'; and 'Marguerite.' She also contributed to the 'Presse,' conducted by her husband, her 'Lettres parisiennes,' which, under the pseudonym of the "VICOMTE DE LAUNAY," attracted great and deserved admiration by their wit and liveliness. As a writer for the stage Madame de Girardin obtained some distinction, two of her most successful pieces being: 'Lady Tartuffe' and 'La joie fait peur.' She also composed two tragedies, 'Judith' and 'Cleopatra,' for the celebrated Rachel; and a little piece by her, 'Le Chapeau de l'Horloger,' became a popular farce in England under its English title of 'The Clockmaker's Hat.'

Girardin, Emile de, ā mēl dē, French journalist and politician: b. Paris 22 June 1806; d. there 27 April 1881. He bore the name of Delamothe till 1827, when he assumed that of his father, who acknowledged him in 1847; and his first attempt in literature was a novel, 'Emile,' in which he pleaded the cause of adulterine children. After the July revolution of 1830 he established the 'Journal des Connaissances Utiles,' and in 1836 founded the 'Presse,' an Orleanist journal with Conservative leanings. Its rivals accused it of being subsidized by the government, and one of the unfortunate results of the quarrels thus fastened on Girardin was his duel with Armand Carrel, editor of the 'National,' in which the latter fell. He promoted Louis Napoleon's election to the presidency, and afterward became a Socialist. In 1856 he sold his share of the 'Presse,' but became its editor again in 1862, eventually abandoning it for the direction of the 'Liberté,' which he maintained till 1870. During the Commune he proposed a scheme for splitting up the republic into 15 federal states. In 1874, however, he founded the 'France,' and both in its pages and in the 'Petit Journal' supported the republic. He wrote a few pieces for the stage; his political ideas he gave to the world in a host of brochures.

Girder, a beam, of wood or metal, spanning the distance from wall to wall or pier to pier, and used to support a superstructure or superincumbent weight, as a floor, the pathway of a bridge, etc. Girders are often compound, the timbers being scarfed together and stayed by truss-work, or fished at the joint. The ends of the girder rest on the wall or pier to an extent varying according to the span; thus for a girder of 10 foot span, the bearing at each end should be 7 inches; for a 20-foot span, 14 inches. The ends rest on templates. Girders are of various sorts, according to the purpose for which they are required. A sandwich girder is one which is composed of two wooden beams with an iron flitch plate between, all bolted together. See BRIDGE BUILDING; BUILDING.

Gir'dler, a small American longicorn beetle (*Oncideres cingulatus*), which in August lays an egg in a hole bored into a twig of a hickory, pear, or other tree, and then gnaws a deep groove below the egg, thus girdling the twig. This kills the extremity and provides a supply of dead wood as food for the grub which is soon hatched. The grub eats all the woody tissue, and within the concealing shell of bark remaining, pupates and passes the winter, becoming a full beetle and emerging the following spring. When this insect is numerous it may do serious damage to forests and orchards.

Girls' Clubs, societies with a membership of girls banded together for recreation, study, mutual helpfulness, etc. Among girls there is apparently less spontaneity than among boys in regard to the formation of clubs, but large numbers of girls are found in clubs organized and to a greater or less degree supervised by older persons. In women's clubs so called, large numbers of girls are found either as regular members or in a junior branch or department. Some large societies, such as the Young Women's Christian Association, do not apply the name club to any of their branches, and could not accurately do so, and yet the opportunities they afford to girls, for entertainment, self-improvement and social intercourse, and the use of rooms for gatherings, reading, and writing, etc., afford to members what is largely equivalent to club membership, a fact appreciated by the girls themselves, who sometimes give as a reason for joining such societies, the wish to be connected with "a club." Many girls are found in the large organization known as King's Daughters and Sons, especially in the junior circles. In such bands, religious or benevolent features predominate, but the social element

is cultivated in a greater or less degree. The Girls' Friendly Society is also largely of a religious nature, but in addition to church and missionary work, it provides opportunities for recreation and for the mental and industrial training of its members. Instruction in hygiene is an important feature, and music receives much attention. The aim of the society is to encourage purity of life, dutifulness to parents, faithfulness to employers, and thrift; and to cultivate a spirit of fellowship and kindliness. It ensures the privileges of the society to its members wherever they may be, by giving them an introduction from one branch to another. The parent society was started in England in 1875 (at a time when much interest was shown in "rescue work") with the central idea of helping young women along preventive rather than reformatory lines. The form of organization follows as far as possible that of the Church of England, being diocesan and parochial. Any girl of good character, 12 years of age or over may become a member, and younger girls may become probationers or candidates. Associate members must be communicants. This society now extends wherever the English language is spoken and is the largest society of girls and women in existence, numbering about 300. The Girls' Friendly Society in America is under the auspices of the Protestant Episcopal Church. Branches were started in Lowell, Mass., and in Baltimore, Md., soon after the organization of the English society, and a central council was formed in 1886. On 1 Oct. 1902 the society reported 435 branches, in 54 dioceses; and a total membership (including associates, probationers, candidates, etc.) of 25,399. There are six holiday houses, belonging respectively to the diocesan branches of Massachusetts, New York, Pennsylvania, Rhode Island, and New Jersey. The organs of the society are two monthly periodicals, 'The Girls' Friendly Magazine,' and 'The Associates' Record.' The central office is in the Church Missions House, New York. Some individual churches maintain girls' clubs as a part of their parish work. The club connected with St. Bartholomew's Church, New York, has a club-room, baths, classes of various kinds, and a mutual benefit fund. In the social, university, and college settlements in large cities throughout the United States, clubs for girls generally constitute an important feature of the work.

The use of the word "girl" in connection with working-girls' clubs is somewhat vague, as the term is very elastic in its application. In most working-women's clubs girls are admitted who have passed the age of 14, but in some cases there are also junior clubs for the younger girls. These "sub-clubs" are to some extent under the supervision of the older members, but usually have their own officers and constitution. The State and city associations of working-girls' clubs secure for the individual clubs belonging to them enlarged advantages and more effective working. The results of united effort are illustrated by the success of the movement for the early closing of stores in Boston in 1896–7, a step due in great part to clubs having a membership largely drawn from girls in stores and factories. One of the objects of the Massachusetts association is to assist clubs in obtaining the services of good teachers, physicians, and lecturers. Among the subjects very frequently taught in the classes connected with working-girls' clubs are plain sewing and embroidery, millinery, cooking, gymnastics, and singing. Lessons in English literature, elocution, French, German, stenography, drawing, modeling, and painting are also offered to many club members. In some of the clubs the teachers are paid, and in others they contribute their services. Besides the more formal lessons, talks are often given to club girls on hygiene, nursing, morals, manners, etc.; and concerts, lectures, and readings, with "evenings of travel" fill many of the evenings devoted to entertainment. Outings of various kinds form a summer feature in many clubs, and vacations are often made possible at cheaper rates than could otherwise be obtained by the members. Large clubs or associations conduct vacation houses at the seashore or in the country. The pleasures and privileges connected with club life form the brightest and most hopeful element in the life of many a self-supporting girl. See BOYS' CLUBS; CLUBS; KING'S DAUGHTERS AND SONS, INTERNATIONAL ORDER OF; LEND A HAND CLUBS; WOMEN'S CLUBS; WORKING WOMEN'S CLUBS.

Girls' Friendly Society. See GIRLS' CLUBS.

Gironde, zhē-rônd, France, a department, bounded north by the estuary which gives it its name, and the department of the Charente; east by Dordogne and Lotet-Garonne; south by Landes; and west by the Bay of Biscay; area, 4,140 square miles. The whole department, with exception of the west, which sends its waters either directly to the coast or the long series of lagoons by which it is lined, belongs to the basin of the Gironde, which is formed in its interior by the junction of the Dordogne and Garonne. The only other streams deserving of notice are the Leyre, which discharges itself into the most southern lagoon; the Ciron, a left affluent of the Dordogne; and the Isle, with its tributary Dronne. The quantity of waste land is very great, amounting to more than one third; while the arable land is rather less than one fourth of the whole surface. Of the remainder about one seventh is occupied by vineyards, and one ninth under wood. The great staple of production is wine. The most celebrated wines are Médoc, Graves, Côtes, Palus, and Entre-deux-Mers. (See WINES.) The trade, which has its centre at Bordeaux, is very important. The principal exports are wine, brandy, corn, flour, fruit, rosin, liqueurs, etc. For administrative purposes Gironde is divided into six arrondissements — Bordeaux, Bazas, Blaye, Lesparre, Libourne, and La Réole. The capital is Bordeaux (q.v.). Pop. (1901) 821,131.

Girondist, jĭ-rŏn'dĭst, or **Girondin,** the name of a great political party in France; one of the most powerful factors in the earlier part of the first French Revolution. When the Legislative Assembly met in 1791, it contained representatives of the upper, the middle, and the lower classes. The Girondists were the party of the middle classes, and were republican in sentiment, but suffered from the lack of a definite policy. They obtained their designation from the fact that their most celebrated leaders, Vergniaud, Guadet, and Gensonné, were members for the department of the Gironde, originally lawyers in the law court of Bordeaux. Sometimes they were called Brissotins from Brissot, their

most eloquent leader. They were the most powerful party in the Assembly, and for a time shaped the policy of their country. When conservative Europe threatened France with invasion, the Girondists in April 1792, declared war, the Jacobins deprecating hostilities, as fearing the result. To overcome their monarchic rivals, the Girondists coquetted with the last-named party, and found that they had gained, not a servant, but a cruel and exacting master. The quarrel between the two arose after the massacres perpetrated in August and September 1792, and the extreme revolutionists ultimately prevailing, an armed mob on 31 May 1793 assailed the Convention, and demanded the imprisonment of 29 Girondist deputies. These were arrested on 2 June, and 21 of them were guillotined on 31 October. Others were subsequently put to death; a few escaping, reappeared in the Convention after the fall of Robespierre.

Girouard, Désiré, dā-zē-rā zhē-roo-är, Canadian jurist: b. Saint Timothée, P. Q., 7 July 1836. He practised his profession as a member of the Montreal bar 1860–95, and was a member of the Dominion Parliament for Jacques Cartier 1878–95. He carried the Deceased Wife's Sister Bill in 1882 and since 1895 has been a justice of the supreme court of Canada. He has published: 'Essai sur Lettres de Change' (1860); 'The Bill of Exchange Act' (1890); 'Lake St. Louis, Old and New and La Salle' (1893).

Girton (gėr'tọn) **College,** England, a noted college for women, instituted at Hitchin in 1869, but removed to Girton, near Cambridge, in 1873. The students, 110 in number, are admitted after an entrance examination; the ordinary course extends over three years, half of each year being spent in college. Degree certificates are granted for the B.A. of Cambridge University.

Girty, gėr'tĭ, **Simon,** American frontiersman and leader of the Indians: b. present Dauphin County, Pa., 1741; d. Canada 1818. He became a second lieutenant of Virginia militia, later an Indian interpreter, deserted to the English in 1776, was appointed an interpreter to the English Indian department, and was declared a traitor by the Pennsylvania legislature. His name was popularly associated with many Indian atrocities on the frontier, although it is likely that he was not at any time commander of a large force and that his prestige among the savages was much less than was supposed. He did, however, lead the Indians who attacked Dunlap's Station (1791) and Fort Jefferson (1791).

Gisborne, gĭz'bōrn, **Frederick Newton,** Canadian telegrapher: b. Broughton, Lancashire, England, 8 March 1824; d. 29 Aug. 1892. He went to Canada in 1845 and soon after engaged in telegraph work. He laid before the Nova Scotia authorities in 1850 a plan for telegraphic communication between Newfoundland and Ireland, and the first cable in America was laid by him in 1852, connecting Prince Edward Island and New Brunswick. In 1870 he was appointed superintendent of the Dominion Telegraph Signal Service.

Gismondite, jĭs'mŏn-dīt, or **Gismondine** (named after C. G. Gismondi, an Italian mineralogist), a monoclinic transparent or translucent mineral of vitreous lustre, its hardness 4.5; specific gravity 2.27; sometimes colorless, sometimes white, bluish-white, grayish, or reddish. It is optically biaxial. Composition: Silica, 35.88; alumina, 27.23; lime, 13.12; potassa, 2.85, and water, 21.10. Occurs in leucitic lava near Rome, and in Sicily.

Gissing, gĭs'sĭng, **George,** English novelist: b. Wakefield 22 Nov. 1857; d. Saint Jean de Luz, France, 28 Dec. 1903. In his stories he has made a remarkable study of the London masses, from the ranks of skilled labor to the most noisome human refuse of the slums, the result being half repulsive and wholly powerful. He has published: 'The Unclassed' (1884); 'Demos' (1886); 'Isabel Clarendon' (1886); 'Thyrza' (1887); 'A Life's Morning' (1888); 'The Nether World' (1889); 'The Emancipated' (1890); 'New Grub Street' (1891); 'Born in Exile' (1892); 'Denzil Quarrier' (1892); 'The Odd Women' (1893); 'In the Year of Jubilee' (1894); 'Eve's Ransom' (1895); 'The Whirlpool' (1897); 'Human Odds and Ends' (1897); 'The Town Traveler' (1898); 'Charles Dickens, a Critical Essay' (1898); 'The Crown of Life' (1899); 'Our Friend the Charlatan'; 'By the Ionian Sea' (1901).

Giulio Romano, joo'lē-ō rō-mä'nō, properly Giulio Pippi de Giannuzzi, Italian artist: b. Rome about 1492; d. Mantua 1 Nov. 1546. He assisted Raphael in several of the latter's works, including the 'Benefactors of the Church' in the Incendio del Borgo, and at Raphael's death completed the 'Battle of Constantine' and the 'Apparition of the Cross' in the Hall of Constantine in the Vatican. He built the Villa Madama, for which he painted a fresco of Polyphemus. In 1524 he accepted the invitation of the Duke of Mantua to undertake for him a series of architectural and pictorial works, and restored the Palazzo del Te, the cathedral, the streets, and a ducal palace at Marmirolo, near Mantua. Among other Mantuan works of his are the 'History of Troy,' in the castle, and 'Psyche,' 'Icarus,' and the 'Titans,' in the Te palace. In Bologna he designed the façade of the church of St. Petronio. Other works are the 'Martyrdom of Saint Stephen,' at Genoa; 'A Holy Family,' at Dresden; 'Mary and Jesus,' and the 'Madonna della Gatta.'

Gizeh, gē'zĕ, **Ghizeh,** or **Geezeh,** Egypt, a town on the left bank of the Nile, almost directly opposite Cairo. It was formerly an important place, beautified by palaces, but now forms a scene of ruins, amidst which the town is built. Five miles to the west are the great pyramids which have been named from this town, and here also is the famous Sphinx. Pop. about 11,500.

Gizzard, a stomach or a part of it or of the alimentary canal where it is unusually muscular and tough, so that it is able to crush or grind solid food. It is not possessed by animals whose food is soft or else is chewed before swallowing; and is best developed among seed-eating birds, which frequently swallow pebbles to assist the gizzard in its grinding work. Birds not accustomed to hard food, if compelled and able to adopt such a diet, will develop a serviceable gizzard. Various fishes, reptiles, crustaceans, insects, worms, and other invertebrates have gizzards. See *Digestive System* under Anatomy; Stomach.

Glacé Bay, Canada, town of Cape Breton Island and County, Province of Nova Scotia, on the extreme eastern seacoast and on the Sydney & Louisburg R.R., 17 miles east of Sydney.

Industries.— The town and the surrounding district are underlaid with vast deposits of coal and almost the entire population is dependent upon the coal mines, five of which are within the town limits and three others closely adjoining. The Dominion Coal Company employs about 5,000 persons and has a yearly output from their mines of over 4,000,000 tons.

Banks and Churches.— There are three banks, branches of those located in other cities. Nearly half the population is Roman Catholic, while the Presbyterians have great predominance over the Evangelical bodies.

Public and Educational Institutions.— Saint Joseph's Hospital is the second largest in America and one of the finest in the province. On Table Head, a bleak promontory one mile east of the town, Marconi completed in December 1902 his first transatlantic wireless telegraph and sent his first wireless messages across the Atlantic. The educational system consists of common and convent schools.

Government and Population.— The town was incorporated in 1901, its affairs being administered by a mayor, elected yearly, and a council of six members, elected for two years. The majority of the population are of Highland Scotch descent. Pop. Glacé Bay and surrounding collieries (1901) 6,945; (1905) 16,000.

Glacial Acetic Acid. See ACETIC ACID.

Glacial Drift. See DRIFT.

Glacial Period, or **Ice Age.** Over nearly all of the North American continent north of the 40th parallel and over a vast tract of the work of moving ice sheets or glaciers, rock surfaces have been ground and polished, great boulders have been carried long distances from the ledges whence they came, and the topography has characteristically rounded outlines. Since the marks of the ice chisel are plainly visible on hard rocks, and even on easily weathered rocks that have been protected by a thin layer of soil, it is evident that the ice finished its work recently.

Effects of Glaciation.— At the opening of the Glacial Period most of the land surface over which the ice advanced was covered by a deep soil grading through partly decayed rock into solid rock. Undoubtedly the ice did not level off the general surface of the country as much as has been supposed, but it wiped off the soil and partly decayed rock, rounded the outlines of hills, broadened north and south valleys and pushed before it or carried along a mass of detritus which formed whenever the ice stopped its advance, a terminal moraine. It is possible that clay and boulder were laid down in a thin sheet under the ice in places at least, forming what is known as boulder clay or till, near where was the southern edge of the ice, oval hills of clay and boulders known as drumlins. Other deposits were formed along the edge of the ice, from material worked over by water and known as stratified drift. These deposits include irregular hills of sand, gravel, and boulders, called kames, and long winding ridges of the same material called eskers. These latter are supposed to represent the filled channels of subglacial rivers. The irregular depressions known as pot holes, in a glaciated region, may sometimes represent where were isolated masses of ice when glacial detritus was deposited all around as the ice sheet retreated. It is in fact in the retreat of the ice front that topography was most modified, the terminal moraines, at each pause in the retreat, dammed river valleys, while the valleys were filled sometimes to a depth of hundreds of feet with detritus. Between the morainic dams in front and the ice in the rear, great lakes were formed, one of these, Lake Agassiz in Minnesota, the Dakotas, and Manitoba being 700 miles long from north to south. As the glacial retreat was recent, streams have not had time to cut down valleys and so a glaciated region is a region of lakes.

Cause and Duration of the Glacial Period.— Though several theories of the cause of the Glacial Period have been proposed, no one has received general acceptance, and the existence of Glacial periods in past geologic ages is still disputed. Probably there were Glacial periods before the Pleistocene. As to the Pleistocene, there is good evidence for believing that northern North America and probably Scandinavia were much elevated at the close of Tertiary time. This elevation of the land caused so heavy a snowfall that snow lay on the ground all the year round, and glaciers started. Another hypothesis, that of Croll, is that owing to variations in the eccentricity of the earth's orbit around the sun the hemisphere having winter when the earth was farthest from the sun, would for a period have protracted winters, and during this period great masses of ice might accumulate. Whatever the cause, the ice sheets formed and advanced. In North America three centres of glaciation are generally recognized, the Cordilleran, along the Rocky Mountains in British Columbia, whence the ice flowed eastward possibly 1,000 miles or more; the Keewatin, near Hudson Bay, whence the ice advanced southwest, south and southeast, reaching as far south as Iowa; and the Laurentide, north of the St. Lawrence River and in Labrador, whence the ice advanced over eastern Canada, New England, and the Central States as far west as the Mississippi River. These ice sheets did not advance simultaneously, but probably in the order named. Their retreat was accompanied or preceded by changes of level, until at the close of the Ice Age, during the so-called Champlain stage, or its equivalent, the Columbian, the ocean covered what is now dry land, and the climate was milder than now. The ice did not advance nor retreat steadily. Some geologists recognize in the Mississippi valley four or five advances and corresponding retreats, and speak of these as epochs or stages. The time since the close of the Ice Age has been variously estimated; average estimates being around 20,000 years. There is good evidence for believing that as much time elapsed between some of the advances of the ice. Hence it is sometimes said that we may be living to-day in an Inter-glacial Period. It is certain that man was in Europe in what is known as the Chellean Epoch, or early Pleistocene. He may have been in America at the same time, but no certain evidence of his presence has been found.

Engineering and Mining Journal.

Glacier Bear, a small gray or "blue" bear (*Ursus emmonsi*) of the St. Elias Alps, Alaska. See BEARS.

Glacier, a current of ice derived from snow. Water, changed into vapor by sun-heat and carried by the winds over frosty highlands, is crystallized into snow. Glaciers take their rise in regions which lie above the snow-line. Upon these regions, from their geographical position and elevation, the quantity of snow that falls exceeds the quantity melted and evaporated. The surplus, instead of accumulating indefinitely, is changed by the pressure of its weight into ice, which, though hard and apparently as brittle and inflexible as glass, flows down toward the sea in beautiful swaying undulating lines, as if soft like honey or tar. Thus the overburdened regions above the snow-line are relieved and a continuous circulation is maintained,— ocean water flying away through the air in the form of vapor, but in returning creeping along the ground in the form of ice, grinding and crushing the rocks that lie in its way, and leaving a heavier track than anything else that moves on the face of the earth.

In general a glacier flows like a river, and drains off snow as a river drains off rain. At different places it moves at different rates, not only along its cross-sections, but along its length and from surface to bottom, as friction and the declivity of its bed varies. The velocity of the swiftest parts of the largest glaciers of the Alps is about from one foot to three feet per day; of the smallest, about as many inches. The lower central part of the Muir Glacier of Alaska flows about 10 feet a day. Some of the Greenland glaciers are said to flow much faster. Glacier motion, however slow, is continuous. It is less in winter than in summer, and slightly less in frosty nights than in warm and rainy days.

Crevasses.— Though obedient to the laws of liquid motion in general, a glacier refuses to stretch, as is shown by its breaking sharply asunder at right angles to tension strains, thus forming the so-called transversal, longitudinal, marginal, and *bergschrund* crevasses. The first two are caused by unevenness of the channel, the marginal by differential motion, the *bergschrund* by the glacier flowing away from the motionless snow attached to the head of its basin. The last is of course a feature of all glaciers: so are the marginal crevasses, since the middle of all glaciers flows faster than the sides; but large central areas, where the bed is regular in slope or slightly concave, are free from crevasses. The largest crevasses are several miles long, 1,000 feet deep or more, and 30 or 40 feet wide, though at first they are usually too narrow to admit a knife-blade. In some places all sorts of crevasses are interlaced, forming labyrinths of yawning gulfs defying the skill and will of the bravest mountaineer who tries to hew a way through them.

Regelation.— The brittleness of ice, with its flowing motion, is partly explained by regelation. In 1850 Faraday discovered that when two pieces of thawing ice are placed together they freeze at the points of contact. Snow at a temperature of 32° F., stuffed into a mold and squeezed, becomes transparent ice. So also, fragments of ice pressed in a mold break, are crushed, and recongealed into a solid mass of the form of the mold, illustrating the breaking of glaciers and their regelation when from change of position the sides of the chasms, great or small, are pressed together.

Moraines.— The life of a glacier is one eternal grind. Its draining streams are always milky with rock mud rubbed off its bed, and separated from the large detached masses by the waters. Moraines, lateral, medial, and terminal, are the general detritus of a glacier and the weathered heights about it, drawn out and arranged by the ice currents, and located as their names indicate. The medial moraines, of which each glacier has one fewer than the number of its tributary glaciers, are formed by the union of two laterals at the confluence of the tributaries, and extend down the trunk in beautiful order. The terminal moraine is made up of parts of all the others. The moraine material, clay, sand, and boulders, of the great continental glaciers of the Ice Age, is often called drift. The detached rock masses, borne along by the ice currents and left in the terminal moraines, or if the glacier reaches the sea, dropped perhaps hundreds of miles away by icebergs, are called erratics.

The most striking features of large glaciers are the medial moraines, the lakes and streams on its surface, the wild ice cataracts corresponding to the cascades and rapids of rivers, and the discharging frontal wall, with its icebergs upheaving, sinking, and roaring amid eternal thunder. Glaciers vary widely in size and form; they may be classified as follows:

(*a*) Continental glaciers, of which only two now exist, the Greenland and South Polar ice caps.

(*b*) Glaciers of the first order, which are more or less river-like, flow into the sea, and terminate in berg-discharging ice cliffs.

(*c*) Glaciers of the second order, which approach the sea, but do not enter it, and of course do not discharge icebergs, waste from melting and evaporation equaling the snow supply.

(*d*) Glaciers of the third order, residual branches of those of the second, separated and made independent by the melting away of the trunks to which they belonged. Nearly all the glaciers of the world are now of this order.

Distribution of Glaciers.— Most of the glaciers of North America are distributed along the mountain ranges of the Pacific coast between lat. 36° 30′ and 36°. About 65 small residual glaciers a mile or less long still linger on the Sierra Nevada of California between lat. 36° 30′ and 38°, at an elevation of 11,000 to 12,000 feet above sea-level. Groups of larger glaciers drain the snow-fields of Mount Shasta and the high volcanic mountains of the Cascade Range in Oregon and Washington. From ice-crowned Mount Rainier, 14,600 feet high, eight glaciers, 5 to 10 miles long, descend into the forests to within 3,000 and 4,000 feet of sea-level. The

broad, lofty mountain chain extending along the coasts of British Columbia and southeastern Alaska is generally ice-laden; the upper branches of the main cañons are occupied by glaciers, which gradually increase in size and descend lower, up to the highest and snowiest region of Alaska between lat. 56° and 61°, where a considerable number flow into arms of the sea. This is the region of greatest glacial abundance on the continent. To the north of lat. 61° the glaciers gradually diminish in size to about lat. 62° 30′ or 63°. Beyond this, to the north end of the continent, few if any glaciers now exist, the ground being comparatively low and the snowfall light.

Glaciers of the third order, a mile or two to 15 or 20 miles long, fill the uppen cañons and hollows of the highest region in countless thousands.

The large glaciers of the second order number about 100. They are distributed along the coast from the mouth of the Stickeen River to Cook Inlet and the Alaska Peninsula, pouring their majestic floods from far-reaching fountains in the white recesses of the peaks. The expanded fan-shaped ends of many of this order are from two to four or five miles wide. The largest among these are the Malaspina Glacier, the Miles, Yakutat, Grand Plateau, Crillion, and La Pérouse, fronting the sea along the St. Elias and Fairweather mountains. The Malaspina is the largest of them all, being about 20 miles long and 65 or 70 miles wide,—a grand undulating ice prairie sloping gently from the base of the St. Elias Mountains, and separated from the sea by a girdle of forested moraines five or six miles wide, except at Icy Cape, where it presents bluffs of pure ice that are being undermined by the waves. The La Pérouse also presents ice bluffs to the open ocean, which at high tide are wave-washed, and small bergs are occasionally detached; but far the greater number terminate a mile or two from the tide line, back of moraines in rather low-spreading crevasse-gashed brows, over which one may easily climb.

The great glaciers of the first order flowing out into deep ocean water and discharging fleets of icebergs number about 31. One, the southmost, flows into the Le Conte Fiord in lat. 56° 50′, 4 into branches of Holkam Bay, 1 into Taku Fiord, 9 into the Glacier Bay fiords, 2 into Lituya Bay at the base of Mount Fairweather, 3 into Disenchantment Bay, and 11 into the wild fiords of Prince William Sound the northmost being a little above the 61st parallel,

The scenery of these fiords is of the grandest description. From wall to wall they are encumbered, often jambed with icebergs, which by the most active glaciers are discharged at intervals of a few minutes with thundering roaring that may be heard 5 or 10 miles away, proclaiming the restless work and power of these mighty crystal rivers, in striking contrast with the dead silence of those of the second order, though they also, except at their decaying ends, are ceaselessly flowing and grinding.

Glacier Bay is the iciest of the inlets which fringe the coast. Both to the north and south of it the glaciers are generally less lavishly snow-fed, and of course give birth to fewer icebergs. Of its nine glaciers of the first order, the Muir is the largest. It is about 50 miles long, the main trunk below the confluence of the principal tributaries is about 25 miles wide and probably about 1,500 feet deep. The berg-discharging part of the sea-wall is less than two miles wide, rises above the water to a height of 250 to 300 feet, and sinks to a depth of about 700 feet.

The grandest of the Prince William Sound glaciers are the Columbia, Barry, Harvard, Yale, and Harriman. Some of the smallest of the noble company descend flowery mountain-sides in the wildest and most imposing ice-cataracts.

Residual glaciers from a mile to 10 or 12 miles long, including neve, are distributed throughout the Rocky Mountain ranges from lat. 43° to 53°. The greater number lie between 50° and 52° 30′ at the heads of the Saskatchewan, Athabasca, and Columbia rivers. The largest groups are magnificent rags and patches of an ancient ice-sheet, some of them covering an area of 40 to nearly 100 square miles, and sending down river-like glaciers six to eight miles long.

Glaciers of the third order abound on the Alps, the Pyrenees, the Caucasus, the Scandinavian Peninsula, the Andes, the lofty snowy ranges of Asia, and on the mountains of New Zealand.

More than 1,000 with an area of about 1,200 square miles, have been surveyed and named in the Alps. The largest are river-like, 10 to 15 miles long, descend into the forests, and terminate at an elevation of 4,000 to 6,000 feet. Most of the smaller ones are like masses of pure snow, and terminate about 2,000 feet higher.

The Caucasus is perhaps about as heavily ice-laden as the Alps. Few of its glaciers are known to descend much lower than 6,000 and 7,000 feet. Those of the Pyrenees are comparatively small.

Many of the glaciers of Norway pour grandly down from extensive neve fields to within 1,000 feet of the sea-level. A few approach the shore and may rank as glaciers of the second order, while one, the only one in Europe of the first order, discharges into Jokul Fiord, near the 70th parallel. Between the larger glaciers flowing toward the heads of the fiords there are many hanging and cascading glaciers, ranged along the brows of plateaus, some of which pour over precipices in separate bergs with loud roaring like that of glaciers discharging into the sea. At the foot of the cliffs the battered fragments are welded, and thus these wild ice-streams, after their plunge through the air, are made whole again, and flow quietly on their way as "regenerated glaciers," the space between their upper and lower parts being only a wider kind of crevasse.

The low-descending New Zealand glaciers almost rival those of the Alps in size, while their beauty is greatly enhanced by the rich vegetation through which they flow.

The glaciers of South America are distributed along almost the whole extent of the Andes. According to Whymper those under the equator attain their greatest size on the snow-laden, storm-beaten summits of Antisana, Cayambe, and Chimborazo. On Cayambe, 12 glaciers of considerable size were counted, flowing from the central neve reservoir, descending to about 15,000 feet above sea-level. To the south of lat. 46° many approach the sea.

On the lofty mountain chains of Asia, especially the snowy Himalaya, Karakoram, Hindu-

1 Small Residual Glacier.

1. Hanging Glacier

2. Front of Muir Glacier.

Kush, Kuen-Lun, and Thian-Shan, thousands of little known residual glaciers still exist. The largest which have been explored are the magnificent Biafo and Baltoro Karakoram glaciers, 30 and 35 miles long, descending to about 11,500 and 12,000 feet.

Excepting Australia, which seems to have lost all its glaciers, Africa is glacially the poorest of the continents. Its only known glaciers are those of the two great snowy mountains, Kenia and Killimanjara, near the equator.

The Arctic islands — Jan Mayen, Nova Zembla, Spitzbergen, Franz-Joseph Land, and many others — are heavily ice-laden. Their largest glaciers are broad sheets discharging magnificent bergs into the frozen sea.

But it is on Greenland and the South Polar lands that glacier ice reaches its grandest development. Excepting a narrow interrupted strip around its shores, Greenland lies buried beneath a continuous mantle of ice thousands of feet in thickness, through which only the tops of its highest peaks, called "nunataks," protrude. From this ice-cap huge glaciers pour into the sea, discharging icebergs of enormous dimensions, some of which sail into the Atlantic thousands of miles from home.

Still greater is the South Polar ice-cap, probably over two miles in thickness. The sea front of some of the glacier currents it pours forth are from 100 to over 400 miles wide, from which flat-topped island-like icebergs 5 to 10 miles long are discharged. Here the great cosmical winter of the Glacial Period still exists in severe, serene grandeur.

Greater Extension of Glaciers.— That a great part of the earth in both the northern and southern hemispheres, now warm and fruitful, was recently covered by flowing, grinding ice, is well known. Over the eastern half of North America from the Arctic regions to lat. 40° or lower, moraines and beds of moraine material variously modified, grooved, scored, and polished surfaces, with other characteristic traces of glacial action, are displayed in wonderful abundance and uniformity.

Along the mountain ranges of the west side of the continent they extend still farther south. The broad Rocky Mountain chain and the plains along its flanks abound in glacial traces on a grand scale. On the Sierra Nevada polished and striated rock surfaces the most evanescent of glacier inscriptions may still be found as far south as lat. 36°; while a degree or two farther north, at an elevation of 7,000 to 8,000 feet above the sea, there are broad glacier pavements in so perfect a state of preservation that they reflect the sunbeams like glass and attract the attention of every observer.

Over the greater part of Oregon, Washington, British Columbia, and the Arctic and sub-Arctic regions about Bering Sea and northwestern Alaska, the rocks in general are less resisting, and the weathering they have been subjected to is more destructive. Therefore the superficial records of glaciation are less clear in these northern regions than in California.

But in all glaciated regions there are other monuments of ice action which endure for tens of thousands of years after the simpler traces we have been considering have vanished. These are the sculpture and configuration of the landscape in general,— the cañons, valleys, fiords, mountains, ridges, and *roches moutonnees*, the forms, trends, and correlations of which are specifically glacial and almost imperishable. These also, it is true, suffer incessant waste, being constantly written upon by other agents. But because they are so colossal in size and peculiar in form and arrangement they continue to stand out clear and telling through every after inscription, showing how great the ancient glaciers must have been, and how great are the geographical and topographical changes they have produced. On the Atlantic coast, where man is busiest, even in the parks and gardens of New York, glaciated rocks shine and call attention to the story of the Ice Period; and in orchards growing on moraine soil around the town of Victoria on the west side of the continent, fruitful boughs drop apples and peaches on the edges of glacier pavements, while the harbor rocks are still bright notwithstanding the centuries of wave-action they have been subject to. Thus strikingly are the works of ice displayed beside the works of man; yesterday in nature's chronology our continent now so fertile was a dreary wilderness of ice. No tale of fairyland is so exciting to the imagination as the story of the works and ways of snow-crystals banded together as glaciers and marching forth from their white tents on the highlands to develop earth's beauty, make beds of fertile food-soil, basins for lakes, valleys for rivers; to separate continents and sculpture their shores into countless islands, bays, sounds, and fringing fiords, then vanishing like clouds.

This change from icy darkness and death to life and light was slow as we count time, and is still going on wherever glaciers exist. The great winter of the Glacial Period is giving place to a great summer before which all the glaciers of the world are wasting away,— the Polar ice-caps, as well as the small shrinking remnants. All are shorter, narrower, shallower than they once were. The world is growing warmer, the snow-supply diminishing. But in trying to account for these changes we must bear in mind that the same sunshine that wastes glaciers nourishes them. In the formation of glaciers an enormous amount of sun heat is required to produce the vapor for the snow of which they are made. For the structure and physics of glaciers, see Agassiz, 'Système Glaciale'; J. D. Forbes, 'Travels in the Alps'; and 'Norway and Its Glaciers'; Tyndall, 'Glaciers of the Alps.'

JOHN MUIR,
Geologist, Explorer, and Naturalist.

Glad'den, Washington, American Congregational clergyman: b. Pottsgrove, Pa., 11 Feb 1836. He was graduated at Williams College in 1859; ordained in the Congregational Church, and after several other pastorates became pastor of the First Congregational Church in Columbus, Ohio, in 1882. He is widely known as a writer on social reforms. His publications include: 'Plain Thoughts on the Art of Living' (1868); 'Workingmen and Their Employers' (1876); 'The Christian League of Connecticut' (1883); 'Things New and Old' (1884); 'The Young Man and the Churches' (1885); 'Applied Christianity' (1887); 'Parish Problems' (1888); 'Burning Questions' (1889); 'Who Wrote the Bible' (1891); 'Tools and the Man' (1893); 'Social Facts and Forces' (1897); 'Art and Morality'

(1897); 'The Christian Pastor' (1898); 'How Much is Left of the Old Doctrine' (1899); etc.

Gladiators (Lat. «swordsmen»), combatants who fought at public games in Rome for the entertainment of the spectators. Gladiators were first exhibited at Rome in 264 B.C., by Marcus and Decimus Brutus at the funeral of their father; and the custom probably originated in Etruria, where a slave was killed at his master's pyre. Gladiators also fought at public festivals and other entertainments. They were at first prisoners, slaves, or condemned criminals; but afterward freemen fought in the arena, either for hire or from choice. Under the empire persons of senatorial rank, and even women, fought in the arena. The regular gladiators were instructed in schools («ludi») established for this purpose. The overseer of the school («lanista») purchased the gladiators, trained them and rented them to those who gave games to the people. Men of position, especially such as aimed at popularity, sometimes kept gladiatorial schools of their own, and hired lanistæ to instruct them. The gladiators fought in the schools with wooden swords. The games were commenced by a «prælusio,» in which the combatants fought with their weapons of wood till, upon a signal, they assumed their arms, and began in earnest to fight in pairs. In case the vanquished was not killed in the combat, his fate was decided by the people. If they decreed his death, the thumb was held up in the air; the waving of handkerchiefs was the signal to save him. In general they suffered death with wonderful firmness, and the vanquished often exposed himself to the death-blow. If he wished to appeal to the people he raised his hand. When a gladiator was killed attendants dragged his body away with iron hooks. The gladiators were often released from further service, and presented with wooden swords, as badges of freedom, from which they were called «rudiarii.» The gladiators were divided into classes, according to their mode of fighting: the «andabatæ» fought blindfold; the «catervarii» fought in troops; the «essedarii» fought in chariots, like the Gauls and Britons. Other classes were the «retiarii,» armed with net and trident but unprotected by any armor, their usual opponents being armed as Gauls, and styled «mirmillones.»

The most celebrated gladiatorial statues are: (1) The Gladiator Borghese, a combatant with extended arm in the act of warding off a blow. It is a statue of the first rank, made of fine grained marble, and is now in the capitol, to which it was restored from Paris 1815. (2) The Dying Gladiator, purchased from the Ludovisian collection for the Museum Capitolinum. It is a dying warrior, and not a gladiator, probably, to judge by his «torques» or twisted necklace, a Gaul, who is wounded and is trying to rise.

Gladiolus, glā-dī'ō-lŭs (Lat. «a small sword»), a genus of plants of the order *Iridaceæ;* sword-lily. It received its name from the shape of its leaves. It has bulbous rhizomes, and the stems are leafy and bear beautiful flowers which, in garden culture, open in midsummer. There are nearly 100 species, some of them natives of southern Europe, the greater number being found in South Africa. Gladiolus is largely cultivated in the United States, and Long Island, N. Y., has important fields of it.

Glad'stone, Herbert John, English politician: b. London 7 Jan. 1854. He was educated at Eton and Oxford. He was private secretary to his father 1880–1; under-secretary home office 1892–4; first commissioner of works 1894–5; and Secretary of State for Home Affairs 1905. He sat in Parliament for Leeds 1880–5, and for Leeds West from 1885.

Gladstone, John Hall, English scientist: b. London 1827; d. 6 Oct. 1902. He was Fullerian professor of chemistry at the Royal Institution 1874–7, and a member of the London School Board 1873–94. He published: 'Life of Michael Faraday' (1872); 'Spelling Reform from an Educational Point of View' (1878); 'Chemistry of Secondary Batteries' (1883).

Gladstone, William Ewart, English statesman, orator, and author: b. Liverpool 29 Dec. 1809; d. Hawarden, England, 19 May 1898. He was educated at Eton and at Christ Church, Oxford. He had distinguished himself greatly as a speaker in the Oxford Debating Society and soon became known as a young man of promise, who would be able to render good service to the Conservative party. He was invited to contest the Scottish burgh of Newark and was elected. He delivered his maiden speech and made a decided impression on the House of Commons. In December 1834 Sir Robert Peel appointed him to the office of a junior lord of the treasury. The great struggle on the question of the repeal of the Corn Laws was now going on. It is a somewhat curious fact that he was not in the House of Commons during the eventful session when the great battle of free trade was fought and won.

Up to the time of the abolition of the Corn Laws, or at least of the movement which led to their abolition, he had been a Tory of a rather old-fashioned school and in 1847 represented Oxford in Parliament. He startled Europe and indeed the whole civilized world in 1851, by the terrible and only too truthful description which he gave in 1851 of the condition of the prisons of Naples, under the king who was known by the nickname «Bomba,» and the cruelties which were inflicted on political prisoners in particular.

By the death of Sir Robert Peel in 1850 he had lost a trusted leader and a true friend. But it was not until after Peel's death that he compelled the House of Commons and the country to recognize in him a supreme master of parliamentary debate. The first really great speech made by him in Parliament was made in the debate on Mr. Disraeli's budget in the winter of 1852, the first session of the new Parliament.

On the fall of the short-lived Tory administration Lord Aberdeen came into office and formed the famous coalition ministry. Lord Palmerston took what most people would have thought the uncongenial office of home secretary; Lord John Russell became secretary of foreign affairs. Gladstone was chancellor of the exchequer. His speech on the introduction of his first budget was waited for with great expectation; but it distanced all expectation. A budget speech from Gladstone thereafter came to be expected with the same kind of keen artistic longing as waits the first performance of a new opera by some great composer.

The Crimean war broke up the coalition ministry. A motion by Roebuck for inquiry into the condition of the army before Sebastopol was carried by a large majority against the government. Lord Aberdeen at once resigned. Lord Palmerston was the one indispensable man, and he became prime minister. Gladstone gave the government of Lord Palmerston a general support, until, after the attempt of Orsini on the life of the Emperor Napoleon III. in 1858; Palmerston introduced his ill-fated Conspiracy to Murder Bill. The government was defeated, Lord Palmerston resigned, and Lord Derby was called on to form a new ministry.

The year 1859 saw Lord Palmerston back again in office and Gladstone as chancellor of the exchequer. The budget of 1860 was remarkable. Gladstone introduced a provision for the abolition of the duty on paper — a duty which was simply a tax on reading, a tax upon popular education and the next session the Lords passed measure for the repeal of the duty. The death of Lord Palmerston in 1865 called Lord Russell to the position of prime minister. Gladstone's mind had long been turning in the direction of an extension or rather expansion of the suffrage. The bill he proposed was defeated (1866), but when Disraeli came into office he introduced a reform bill of his own, which was practically a measure of household suffrage for cities and boroughs.

About this time the attention of Gladstone began to be attracted to Ireland. He made short work with the Irish State Church. He defeated the government on a series of resolutions foreshowing his policy; the government appealed to the country; the Liberals returned to power, and Gladstone became prime minister (1868). In his first session of government he disestablished and disendowed the state Church in Ireland. In the next session he passed a measure which recognized the right of the Irish tenant to the value of the improvements he had himself made. For the first time in English history a system of national education was established. The Ballot Act was passed for the protection of voters. The system of purchase in the army was abolished — by something, it must be owned, a little in the nature of a *coup d'état*. Then he introduced a measure to improve the condition of university education in Ireland. The bill was thrown out and he tendered his resignation of office. Disraeli came back to power, and Gladstone retired from the leadership of the House of Commons (1874).

For a while he occupied himself in literary and historical studies, and he published essays and pamphlets. But even in his literary studies he would appear to have always kept glancing at the House of Commons. The Parliament which had gone from the spring of 1874 was dissolved in the spring of 1880, and Gladstone, after the famous Midlothian campaign had become prime minister once more.

It was an unpropitious hour at which to return to office. There were troubles in Egypt; there was impending war in the Sudan, and in South Africa. There was something very like an agrarian revolution going on in Ireland; and the Home Rule party in the House of Commons was under new, resolute, and uncompromising leadership. It is to the credit of the Conservative party that after a while they co-operated cordially with Gladstone in his reforming of 1885.

The use he made of office and power astonished his enemies, and startled and alarmed not a few of his friends. His government had had in the years between 1881 and 1885 to fight a fierce battle against the policy of obstruction organized by Parnell, the leader of the Home Rule party. But when the elections under the new and extended Reform Bill were held, and the Irish Nationalist party came back 87 members out of the whole Irish representation of 103, in March 1886 he brought in a measure to give a statutory parliament to Ireland. In 1893 his Home Rule Bill was carried in the House of Commons, but was thrown out in the House of Lords. Owing to the increasing infirmities of age, especially impaired eyesight, the veteran statesman resigned 3 March 1894, and was succeeded by Lord Rosebery. He still took an interest in public affairs and busied himself with literary work. In January 1898 he published his reminiscences of Arthur Hallam; but falling seriously ill, after some months of suffering borne with noble fortitude, he died at Hawarden. He was buried in Westminster Abbey. Among Mr. Gladstone's works are: 'The State in its Relations with the Church' (1838); 'A Manual of Prayers from the Liturgy' (1845); 'Two Letters on the State Persecutions of the Neapolitan Government' (1851); 'Studies on Homer and the Homeric Age' (3 vols. 1858); 'A Chapter of Autobiography' (1868); 'Juventus Mundi' (1869); 'The Vatican Decrees, bearing on Civil Allegiance' (1874); 'Vaticanism' (1875); 'Homeric Synchronism Gleanings of Past Years' (7 vols. 1870); 'The Irish Question' (1886); 'A Translation of Horace' (1894); and 'The Psalter with a Concordance.'

Glagolitic (glag-ō-lĭt'ĭk) **Alphabet,** a Slavvonic alphabet classed as ancient Bulgarian. There is a MS. of the 11th century written in this alphabet in the Vatican, containing extracts of the Gospels for each day in the year; there are extant also three other MSS. written in the same letters.

The origin of this alphabet is undiscoverable. It is older than the Cyrillac; it may be a modification of Greek cursive writing; perhaps it is connected with Armenian and Albanian alphabets. Its use is confined to the liturgical books of Dalmatian Slavs. Cyril, a monk of Constantinople invented the Cyrillac alphabet, of which this has sometimes been considered a variant. Both of these differ from the current Russian alphabet.

Glagolitsa. See GLAGOLITIC ALPHABET.

Glair (Lat. *clarus*, clear, Fr. *glaire*), the white of eggs prepared and used as a varnish for preserving paintings. For this purpose it is beaten to an even consistence, and commonly mixed with alcohol to make it work more freely, and with a little fine sugar to give it body and prevent it cracking, and then spread over the picture with a soft brush. Bookbinders also use it for finishing the leathern backs of books.

Glaisher, glā'shėr, **James Whitbread,** English meteorologist: b. Lewisham, Kent, 7 April 1809; d. Croydon, Surrey, 7 Feb. 1903. In 1840 he became superintendent of the magnetical and meteorological department of the Royal Ob-

servatory, a post which he held for 34 years. Between 1862 and 1866 he made 28 balloon ascents for the purpose of studying the higher strata of the atmosphere, on one occasion reaching a height of over seven miles. He was the founder of the Royal Meteorological Society, became a Fellow of the Royal Society in 1849, and wrote numerous papers on subjects relating to astronomy and meteorology.

Glance, English equivalent of the German *glanz*, a term applied to opaque minerals of which the high lustre and color indicate their metalliferous character. The following are some of them: *Antimonial copper-glance*, or wölchite, sulphide or antimony, copper, and lead, with a little iron; *antimony-glance*, or stibnite, sulphide of antimony; *bismuth-glance*, or bismuthinite, sulphide of bismuth; *cobalt-glance*, or cobaltite, sulph-arsenide of cobalt sometimes with a little iron, also nickel and antimony; *copper-glance*, sulphide of copper; *glance-blende*, or manganese blende, sulphide of manganese; *glance-coal*, anthracite; *iron-glance*, or specular iron, oxide of iron; *lead-glance*, sulphide of lead or galena; *nickel-glance*, amoibite or gersdorffite, arsenide and sulphide of nickel, with cobalt, iron, etc.; *silver-glance*, sulphide of silver; *yellow-gold-glance*, or sylvanite, telluride of gold and silver; *zinc-glance*, silicate of zinc. German miners use almost indifferently the term *glanz* and *kies*, the latter signifying pyrites, as iron pyrites, copper pyrites; but glance is not so frequently used among American and English miners, though copper-glance, antimony-glance, are sometimes employed by scientific men as well as in the mines.

Glan'ders, the most dangerous form of equinia, and one of the most formidable diseases to which horses are subject. It is diagnosed by a discharge from one or both nostrils, with a hard enlargement of the submaxillary glands. It is distinguished into acute and chronic. In acute glanders the discharge from both nostrils is so great as ultimately to impede respiration and produce death from suffocation. Chronic glanders may run on for years before it terminates in the acute form of the disease. The discharge is usually confined to one nostril, is only occasional and sometimes trivial, with a moderate swelling of the gland on the affected side. The only other symptom of disease is a harshness of the coat. In the latter stages the discharge becomes offensive. The disease is highly infectious, and acute glanders may be communicated to healthy horses and asses, while the animal first affected is still able to feed and work apparently as well as ever. It may even be communicated to man by the pustular matter coming in contact with any part where the skin is broken; and not a few deaths have happened through this cause. The disease is often difficult to determine, as the discharge is only offensive in the latter stages. The symptoms may be mitigated by tonics and other treatment, but it is rarely if ever cured. The disease is now known to be produced by a species of bacillus about the size of the tubercle-bacillus. See FARCY.

Glandina, glăn-dī'na, a genus of large spirally elongated snails (q.v.), which attain their maximum development in the southern United States and in Mexico. They include many species, all graceful in outline and beautifully colored. A rosy species (*Glandina truncata*) is common along the coast of Florida and westward, which varies greatly in size according to its circumstances, in favorable localities reaching a length of four inches. These mollusks are most commonly found among the marsh-grasses, where they hunt for and devour other snails by filing through their shells and rasping away the flesh by means of their lingual ribbons. Marine mollusks and other animals are also attacked.

Glasgow, Ky., a city and county-seat of Barren County, 100 miles south of Louisville, on the Louisville & N. R.R. It is situated near the oil well district, and has manufactures of plows, wagons, tobacco, sashes, and blinds. There are several public schools, 3 banks, and weekly newspapers. The Liberty Female College is located there. Pop. (1900) 2,019.

Glasgow, Scotland, the second largest city in the United Kingdom, situated in the counties of Lanark and Renfrew, on both banks of the Clyde. Much the largest and most populous portion of the city is in Lanarkshire, and of this portion again the greater and more important part is on the right bank of the Clyde. Glasgow now forms a county of a city as well as a municipality, and the boundaries were recently extended; but the contiguous police burghs of Partick, Govan, Kinning, Park, and Pollokshaws, with other populous areas, are as yet outside its limits. The north and south sides of the river are connected by bridges and ferries, the latter at convenient intervals. The bridges are: the Caledonian Railway bridge, leading into and out of the Central Station; Glasgow or Broomielaw bridge, in line with Jamaica Street, a stone bridge 80 feet broad, recently rebuilt and widened, the features and materials of Telford's earlier structure (1835) being retained; Portland Street Suspension bridge; Victoria bridge (stone), Stockwell Street; the Union Railway bridge (stone and iron), used by the Glasgow and Southwestern Railway Company; the Albert bridge (stone and iron), close to Glasgow's oldest park, called The Green; Rutherglen bridge; and Dalmarnock bridge. Tunnels under the river have also been formed for cross-river traffic, and a cable subway running in a circular course twice passes from side to side in this way. There are underground and various other local railroads owned by the corporation, and small harbor steamers for passengers.

Glasgow is built mostly of a light-colored sandstone quarried in the neighborhood, but a red sandstone brought from a distance is now being freely employed. The streets are in general wide and straight, running mostly at right angles. Glasgow as a whole is excelled by few cities in the kingdom in architectural beauty and general amenity of appearance. It possesses few squares worth mention, the chief being George Square, in the heart of the city. On the other hand, it has now a series of fine parks and recreation grounds. The chief are: the Green (140 acres), with a People's Palace and winter gardens; Kelvingrove Park, intersected by the Kelvin; the Queen's Park; Bellahouston Park (178 acres); and Alexandra Park. The

city also possesses botanic gardens, with extensive ranges of hothouses and greenhouses.

Pre-eminent among edifices stands the Cathedral, Glasgow's only ancient building, on the edge of a ravine separating it from the Necropolis (the chief public cemetery). It is a large Gothic edifice in the early pointed style, with tower and spire rising from the centre, but without transepts; length of interior, 319 feet; width, 63 feet; height of nave, 90 feet; of choir, 85 feet; spire, 225 feet. It is especially distinguished for the beauty of its crypt, which is one of the most beautiful in Great Britain. The cathedral as it at present stands is supposed to have been begun before 1197, and completed within the 15th century. The chancel is used as a parish church, and the structure is under the charge of the government. Many of the other churches are marked by a high degree of architectural merit. Among other buildings are those of the university opened in 1870, and covering about four acres of ground, on Gilmorehill, a magnificent site overlooking the Kelvingrove Park. The main building is an oblong rectangular pile in the Collegiate Gothic style of the 14th century, about 600 feet long by 300 broad, divided into two quadrangles of 180 feet square, united by a centre building, and having a tower and open-work spire about 300 feet high. Another edifice of similar importance is the municipal building or city chambers, accommodating various departments connected with the corporation. This is an imposing structure in the Italian or Renaissance style, occupying a large area, and filling up the whole side of George Square. Other buildings abutting on the same square are the Bank of Scotland, and Merchants' House. Among other buildings are: The United Free Church College, a building in the Italian style with a high tower; the Royal Exchange, in the Corinthian style surmounted by a circular clock tower; the Stock Exchange, in the Venetian Gothic style; the Athenæum buildings, the Deaf and Dumb Institution, the Christian Institute, the Royal, the Western, and the Victoria infirmaries, the St. Enoch Station and Central Station hotels, the buildings of Glasgow and West of Scotland Technical College, the Procurators' Hall, etc. In George Square are statues of Queen Victoria, Prince Albert, James Watt, Lord Clyde, Robert Burns, Dr. Livingstone, Sir John Moore, etc., and a tall fluted Doric column surmounted by a statue of Sir Walter Scott. Elsewhere there are also equestrian statues of King William III. and of Wellington, besides an obelisk to Nelson in Glasgow Green, etc.

The educational institutions after the Glasgow University (q.v.) are St. Mungo's College; Anderson's College Medical School (founded 1796); the United Free Church College (for divinity students); the Glasgow and West of Scotland Technical College; Queen Margaret College for women, connected with the university; the Glasgow Academy and the Kelvinside Academy; the normal institutions of the Established Church and United Free Church; Allan Glen's School connected with the Technical College; the Glasgow School of Art; School of Music in connection with the Athenæum; and the Veterinary College.

The principal libraries are the University Library (175,000 vols.), the Mitchell Free Library (about 140,000 vols.), the libraries of the Faculty of Physicians and Surgeons and of the Faculty of Procurators, the combined Glasgow and Stirling's Libraries (45,000 vols.), and Baillie's Library. The Public Libraries Acts are to be adopted, and Andrew Carnegie has given $500,000 for the establishment of district libraries.

The town council consists of 75 councilors, elected by 25 wards, and of the dean of Guild (elected by the Merchants' House) and the deacon-convener of the trades (elected by the Trades' House), as ex officio members. The lord-provost, 14 bailies, and a river bailie and deputy bailie are chosen from among the councilors. The river and harbor are under the management of the Clyde navigation trustees.

The manufacturing industries of Glasgow, including also those of the surrounding and dependent districts, are unequaled for variety by any manufacturing town in the kingdom, with the exception, perhaps, of London. Among the older industries of importance are those connected with cotton, linen, and wool, including spinning and weaving, dyeing and bleaching, calico printing, and Turkey-red dyeing in particular. But the Glasgow of to-day is most largely dependent on iron and coal, and the importance of its textile industries is relatively less than formerly. It is the leading market for the whole iron production of Scotland, and there are blast furnaces and collieries within the city boundaries. The most important industry is ship-building and the connected trades, the Clyde, which was the birthplace of steam navigation in Europe, having ever since been closely associated with the growth and development of steam ship-building and marine engineering. Some 300,000 tons of shipping are usually built yearly. The commerce of Glasgow is commensurate in extent with the importance of its manufactures, and is closely associated with these. The value of foreign and colonial produce imported in 1900 amounted to $70,000,000; that of the home produce exported was $92,000,000. Large imports of tea, cotton, and other produce are received coastwise from London and Liverpool. The rental of Glasgow in 1900 was $27,000,000.

All the leading banks of Scotland are represented in Glasgow by numerous branches, and the Union Bank of Scotland and the Clydesdale Bank have their head offices here, as also have some insurance companies. The principal railway systems are the Caledonian, North British, and Glasgow and Southwestern, all of which have large modern termini in the heart of the city. There are underground railways, and the cable subway already mentioned, which twice passes under the river. The Forth and Clyde and Monkland canals form auxiliary means of communication.

Glasgow has long been distinguished for the energy and public spirit of its local government. The trade and commerce of the city, its amenity, and its sanitary condition have all profited in turn by liberally conceived measures, successive provosts having vied in associating their reign with important schemes of improvement. The improvement of the navigation of the Clyde was the first and greatest of these schemes of local improvement. The gas works belong to the corporation, and the gas is supplied at a low rate. The streets are now partially lighted

by electricity, and the corporation has erected great power houses.

Beyond its own commercial growth Glasgow has contributed little to general history. Although the most important city of Scotland, it has never been the capital of a county. Its local history is, however, peculiarly rich in characteristic incidents. Ancient Glasgow was situated on the high ground immediately around the cathedral, from which it first extended down to the river, and afterward spread in all directions. The city was for many centuries purely ecclesiastical. Its nucleus has been traced back as far as the origin of the bishopric founded by St. Mungo about 560. The convents of the Gray and the Black Friars had elegant churches attached to them, one of which at least is supposed to have been earlier than the cathedral. Rottenrow, Castle, Drygate, Kirk, High, Saltmarket, Gallowgate, Bridgegate, and Trongate streets are known to have been in possession of the public as early as 1100. The bishopric was refounded by David, Prince of Cumberland, in 1115. John Achius, his tutor, who was appointed bishop, is said to have begun the cathedral. In 1176 weekly markets and annual fairs were instituted by the prior of Grayfriars. The city was erected into a royal burgh in 1180. Provost and bailies are mentioned in a charter dated 1268.

The corporation of fishers was probably the earliest trade incorporation. The first Stockwell street bridge was built by Bishop Rea in 1345. In 1350 St. Ninian's Hospital for lepers was founded. In 1393 a mint was erected in Drygate Street. The tower of the cathedral was commenced by Bishop Lauder in 1408. In 1546 the shipping of Glasgow is mentioned in an order of the privy council. Some persecutions occurred in Glasgow during the period of the Reformation. The Confession of Faith was signed by 2,250 persons in 1581. From this time till about the time of Cromwell's visit in 1650 the most powerful governing body in Glasgow appears to have been the session, which issued its orders on all manner of subjects with a refreshing ignorance and contempt of law. The General Assembly which abolished episcopacy met in Glasgow Cathedral in 1638. Two great fires devastated the city, in 1652 and 1657. In 1748 the first delft works were erected, and in this works in 1763 Watt set up the model of a steam-engine. The steam-engine was introduced in a cotton-mill in Glasgow in 1792. The power loom being now introduced, the city soon became an important centre of the cotton manufacture. In 1816 the first vessel was despatched to the East Indies. Since then the trade has extended all over the world, the improvement of the river keeping pace with this extension. The cotton manufacture reached its highest point about 1860, and since then has both actually and relatively declined, but ship-building, engineering, etc., have more than made up for this. In 1888 a highly successful exhibition was held, and in 1901 a still larger was opened. The progress of Glasgow will be seen from the following figures of population: (1610) 7,644; (1660) 14,678; (1708) 12,766; (1740) 17,034; (1763) 28,300; (1785) 45,889; (1801) 77,385; (1811) 100,749; (1841) 255,650; (1871) 477,732; (1881) 511,415; (1891) 565,714; (1901) 760,423.

Glasgow, The University of, a corporate body founded by a bull of Pope Nicholas V., dated 7 Jan. 1450–1, as a "*studium generale tam in theologia et in jure canonum et civili quam in artibus et in quacunque licita facultate*," with the power of creating masters and doctors, who, together with the readers and students, were to enjoy the same privileges and immunities with the University of Bologna. A body of statutes was prepared, and the university established by the bishop and chapter in the same year. The university appears at first to have had neither property nor endowment. A purse was formed of the perquisites procured from matriculations, examinations, degrees, etc., and some of the earlier members bequeathed the patronage of a few small chaplaincies; but through the zeal of its founders and the civil and ecclesiastical immunities accorded to it, the new school of learning prospered, though in circumstances so little in accordance with modern notions of educational requirements. The clergy were induced to attend by offers of exemption from taxation and residence. The lectures in theology and in canon and civil law were read at the convent of the Dominicans; but the students of arts soon became so numerous that a house was provided for their residence called the pædagogium, and regular teachers were appointed.

In 1460 James, Lord Hamilton, bequeathed to Duncan Bunch, regent of the College of Arts, and his successors, a tenement in High Street, with four acres of land adjoining, for the use of said college. On this ground the classes of the university continued to meet for 410 years. In 1577 James VI. prescribed rules for the government of the university, and made a considerable addition to its funds. This new charter is called the Nova Erectio. It provided for a principal to teach theology and Holy Scriptures, who was also professor of Hebrew and Syriac; and three regents, of whom one taught Greek and rhetoric; another dialectics, morals and politics, with arithmetic and geometry; the third, physiology, geography, chronology, and astrology. Between this period and the Restoration the university continued to flourish, and the number of its professors increased; but at the Restoration the reestablishment of the Episcopacy deprived it of a great part of its revenues, and three of its chairs fell into abeyance. After the Revolution it continued gradually to expand the scope of its teaching, and has numbered among its professors and graduates many distinguished men. In the end of the 18th century it obtained by bequest the valuable anatomical museum, library, and other collections of the famous Dr. William Hunter. Later the old buildings became quite inadequate, and were sold. A grant for new buildings was procured from the government, a small sum was available from college funds, and public subscriptions were procured. In 1870 new buildings at Gilmorehill, which cost over $2,000,000, were erected.

The University of Glasgow comprises five faculties, namely, arts, science, medicine, law, and theology, the faculty of science having been recently added. The oldest chairs are those of moral philosophy (1577), natural philosophy (1577), logic and rhetoric (1577), Greek (1581), divinity (1630), Latin (previous to 1637), mathematics (revived 1691). In the first 20 years of the 18th century six professorships were either originally founded or revived,

namely, Latin, Oriental languages, civil law, medicine, church history, anatomy; astronomy was added in 1760. The remaining 18 professorships were founded in the 19th century. The university was reconstituted by the Scottish University Act, 1858, and a similar revolution was effected under the act of 1889.

The students number about 2,000. There are numerous bursaries connected with the university, the annual total value of which is about $40,000. There are also medals and prizes given in connection with the various classes, and scholarships or exhibitions are awarded to students who prove successful in certain examinations. The Snell exhibitions, established in 1677, send 10 (or fewer) Glasgow students to Oxford. They are tenable for five years, and each exhibition yields $400 per annum. The two Eglinton fellowships, founded in 1862, tenable for three years, and each worth $500 annually, are awarded by competition to students who have just graduated in arts. Three Ewing fellowships, of the value of $400 per annum, and tenable for not more than five years, are also awarded by competition among graduates in arts. The Luke fellowship, about $400 per annum, tenable for three years, is awarded to graduates for excellence in English literature and history. The George A. Clark scholarships, four in number, are tenable for four years, their annual value being about $900. The examinations are respectively in classical literature, mental philosophy, mathematics, and natural science. The Metcalfe fellowship, founded 1870, annual value $500, tenable for three years, is designed to encourage studies in higher mathematics, practical astronomy, civil engineering, and chemistry. There is also the Black theological fellowship, worth $700 annually.

Glass, a hard, brittle, transparent substance, formed by fusing together mixtures of the silicates of potash, soda, lime, magnesia, alumina, and lead in various proportions, according to the quality or kind of glass required.

Flint glass is used in making table-ware and many articles of domestic furniture and fittings. The molten glass is taken from the pot by a ponty, and is blown or pressed into shape, or, by a combination of operations, is held in a mold while being blown.

Crown glass is taken by the ponty from the pot, and is then blown and whirled until it becomes globular. A ponty tipped with molten glass is applied to the bulb, the blowing tube is detached, leaving a hole. The globe being again whirled, the glass flashes into a circular disk, adhering by a boss in its centre to the ponty. Crown and flint glass are combined in the manufacture of achromatic lenses.

Sheet glass is glass withdrawn by the ponty from the pot and blown and whirled till it assumes a cylindrical form. The ends beings cut off, and the cylinder slit longitudinally, the sheet is heated, pressed, and rubbed until it is flattened out. This is also called cylinder glass or broad glass.

Plate glass is made by pouring it upon a table which has a marginal edge of a height equal to that designed for the thickness of the glass. A roller travels over the table, on the ledges and flattening out the glass, which is thus made of equal thickness throughout.

Toughened glass is made by heating till it is about to soften, and then plunging it into a bath of oil at a greatly lower temperature. Usually a mixture chiefly of oily substances, such as oils, tallow, wax, resin, and the like, is put in the bath; and some manufacturers who worked the process, for a time dropped the newly made glass vessels, while still hot, into the oleaginous mixture, by which plan neither reheating nor annealing by the ordinary process is required. After the articles acquire the temperature of the bath, they are removed.

Painted or *stained glass* is of two styles, enamel and mosaic glass. In enamel glass proper, certain fusible pigments are painted on a sheet of white glass, which is then fired and the result is a picture the tints of which even in the high lights are not wholly transparent. A modification of this method produces its picture partly by enameling on white glass, partly by the use of pot-metal glass the color of which is heightened or modified by the use of enamels.

Of the origin of glass manufacture we cannot speak with certainty. Pliny states that the ancient Phœnicians discovered by a happy accident how to make it. He relates that certain Phœnician merchants preparing a meal upon the sea-shore set their cooking vessel on a mass of natron (sub-carbonate of soda) and the union of the sand and alkali, when subjected to the fire, resulted in vitrification that drew the men's attention and led to subsequent efforts at imitation. According to Egyptologists the Egyptians made sham jewels of glass at least 5000 or 6000 B.C. In some of the most ancient tombs scarabs of glass have been found imitating rubies, emeralds, sapphires, and other precious stones, and the glass beads found broadcast in three parts of the globe were quite possibly passed off by traders on confiding barbarians as jewels of great price. As a medium of trade, beads are evidently of great antiquity. Those known as aggry have been attributed to both Egyptian and Phœnician sources. The beads vary greatly in color and pattern and some of them show fine workmanship and marked beauty. During the period when Egypt was part of the Roman empire much glass was produced in the Nile valley.

It is probable that the great centre of glass industry of mediæval and more recent times, Venice, received its early impulse and lessons from Constantinople. The art began there with the beginning of the city in the 7th century A.D. and there was a marked improvement after the conquest of Constantinople in 1204, and in 1291 the establishments were removed to the island of Murano, the manufacturers forming a guild with a register of nobility, and guarding their secret with the greatest jealousy. In 1436 their color glass came into note, and continued so till the close of the century; and in the 16th century lace patterns and mirrors were introduced. In the 15th and 16th centuries plain glass with tasteful ornaments in gilt and enamel; in the 16th, cracked lace and reticulated glass, and in the 17th century variegated or marbled glasses were produced.

The Venetian glass enjoyed for a long time the monopoly of commerce, and within recent years there has been a marked revival of the skill and enterprise of Venetian craftsmen. In Germany the oldest glass dates from the [illegible] century, and consists of goblets and tankards of white color, enameled with colored coats of

arms and other devices, millefiori, and schmeltz glass. Engraved glass was first introduced by Casper Lehman at Prague in 1609 under imperial protection, and continued by his pupil Schwanhard; and ruby glass by Kunckel in 1679. In 1665 20 Venetian glass workers were brought by Colbert to Paris, where they set up the blowing of glass and the silvering of mirrors, the famous mirror hall in Versailles having been furnished by them. In 1688 an exclusive privilege of making large plates of glass by casting was conferred on Abraham Thevart. The name Thevart was assumed by a syndicate of capitalists formed to develop and work the invention of Louis Lucas de Nehon, who was the real inventor of plate glass and the founder of the Gobain works, one of the most extensive plate glass works in the world. In France oxide of lead flint glass was made at St. Cloud in 1784; another manufactory was subsequently established at St. Louis in 1790; and the St. Cloud establishment was removed to the vicinity of Mont Cenis, where it flourished till 1827.

It is uncertain whether glass was made in England before the 16th century, as that mentioned may have been imported from Flanders or Venice. In 644 Benedict Biscop introduced makers of glass windows into Northumbria; but window glass was not in general use for windows till the 15th century. Pressed glass was invented in the United States. See GLASS BLOWING; GLASS; CUT; GLASS MANUFACTURES IN AMERICA; GLASS STAINING.

GEORGE W. HASTINGS.

Glass Blowing, a mode of manufacturing various articles by taking a mass of viscid glass from the melting pot on the end of the blowing tube, and then inflating the mass by blowing through the tube, rolling on the marver, and exposing it at the furnace opening where its contained air is expanded and itself enlarged.

Although the forms into which blown glass is worked up are endless, the general methods of manufacture are the same, and a description of first-class lamp chimney works is illustrative of the blown glass industry in general. Perhaps the most important feature in the manufacture of lamp chimneys, or indeed of any form of glass-ware, is the mixing of the ingredients. As in the case of plate glass, the body of the mixture consists of a sand which is as nearly pure silica as can be obtained. The sand is quarried from silica rock, then thoroughly ground and sifted through a 40-mesh screen, the material being received at the works in the prepared condition. The second most important ingredient is litharge; while potash and soda are used as fluxes. When the above mixture is used for the best quality of lamp chimneys, about 50 per cent of the total is silica. The sand is melted in what is known as the furnace, the first and greatest of the glass blower's implements; it consists of two large domes set one above the other; the lower one stands over a large perforated grating (level with the ground), and is fired by gas, a large arch beneath conveying air to the furnace. In the sides of the lower dome as many recesses or mouths are made as there are workmen to make use of the furnace, and before each mouth a pot of glass mixture is placed; the pots are very large, like crucibles, and are molded from a specially prepared and very carefully kneaded pot clay; they stand 50 inches high and are generally 44 inches in their largest diameter, and will hold from three to four hundredweight of liquid glass; they are supported upon three small piers of brickwork resting on the floor of the furnace. The form of the furnace reverberates the flame from the roof down upon the pots, and they are placed at some distance within the furnace so that the flame may get between the wall and the pots. It takes about 24 hours to melt the contents of a pot.

The upper dome is used for annealing the glass, and is exactly similar to a large oven; it has three mouths, and a small flight of steps leads up to each. It is built upon the lower dome, its floor being made flat by filling up round the roof of the lower dome with brickwork; a small chimney opens from the top of the lower dome into the middle of the floor of the upper one, which conveys the fumes and smoke from it, and a flue from the upper dome leads it completely from the furnace.

The blowing is done with a long iron tube known as the blowpipe, which has a mouthpiece at one end, and is swelled out and thickened into a bell-mouth form at the lower end. In the process of blowing, the operator dips the thickened end into the melting pot and twists it around till he has gathered up a ball of molten glass of the desired size. The blowpipe is then withdrawn from the furnace and the ball of glass is rolled out to a conical shape on a plate and slightly inflated by blowing through the tube. The blowpipe is then handed to the second operator, who completes the operation of blowing. The bubble, if we may so call it, of glass is thicker and heavier at its lower end, and to secure the elongated form necessary in lamp chimneys the operator swings the blowpipe to and fro, thus causing the bubble to stretch by its own weight. By thus alternately swinging and blowing he brings the bubble to the required length, and approximately to the required diameter, and then places it within a hinged mold, which is opened to receive it, either by himself or one of his assistants. He then twists the pipe and blows at the same time, thus pressing the glass against the inner walls of the mold. The tube with the molded chimney attached is then withdrawn from the mold, and handed to another operator, who, with a pair of spring tongs, forms the flaring top of the lamp chimney and marks a sharp depression just outside its base, where it is to be broken away from the blowpipe. Although a large amount of blowing is done by hand and mouth, increasing use is being made of what is known as the Owens blowing machine, which substitutes mechanical for hand power. See GLASS; GLASS MANUFACTURES IN AMERICA.

Glass Crab, an immature condition of certain crabs (*Palinurus* and its allies) which for a time are flattened and perfectly transparent, as if formed of a sheet of glass, and have no resemblance to the parent form.

Glass, Cut or Incised. Glass is a singularly versatile material, at once refractory and yielding, yet lending itself to use in thousands of ways. It is as a means of artistic expression that it is chiefly interesting, for its utility is beyond all question. The iridescent chatoyant colors of antique glass — Nature's destructive action — do not distract us from the charm of perfect

form. Venetian glass, the beautiful product of the lagoon-island of Murano, is so very impracticably fragile that even its possession is a care. Probably glass would have remained in a rather humble position if it had not been that a Bohemian glass-worker more than 200 years ago conceived the idea of a new invention, which was destined to change the glass product of the world. He thought of making the heavy "flint" or "lead" glass larger as regards the dimensions of the walls of the article, in order that he might have more stock to work on, so that he could deeply incise or cut the glass to form patterns, the sides of the rough cut being in turn polished to give the effect of a many-faceted jewel. The success of the new *objet d'art* was not immediate, and it was only when the crude designs and imperfect workmanship of the earlier cutters gave way to the labors of highly skilled artisans directed by talented designers that cut glass, or "art glass," as we might term it, took the place to which its great beauty entitles it. It is to America that we must look for the perfection and the superiority of design and skilful workmanship of this branch of the industry. There is no such thing as absolute interchangeability in the glass-cutting establishment, and the artistic bent of the various cutters is encouraged.

The peculiar product known as glass has as a base silica, which is fused with alkalies and metallic oxides to form a hard transparent substance. It can be wrought in various ways, and is susceptible of a high, and, when properly cut, a lasting finish. The raw materials consist of a sand, so called, of exceptional quality as regards sharpness and color. It is not a sand in the ordinary sense of the word, but is a quarried rock which has been crushed. This accounts for the uniformity of its color, which is so necessary in producing a steely-blue white glass, which is to be used for giving the prismatic colors caused by the cutting process. The red lead, saltpeter, and sodium carbonate are accurately mixed with the sand, and a small percentage of white arsenic or manganese is added to bleach or clarify it. The proportion is varied according to the nature of the finished product. A glass furnace is a large round or oval fire-brick oven, capable of holding an aggregation of melting pots, which rest under a floor in common under a dome called a crown. These pots are made of unbaked fire-clay. A mouth gives entrance for the raw material and the workmen's blowpipes, to which the molten glass adheres. A furnace may contain as many as sixteen pots arranged radially on the floor of the furnace. They are heated before setting, and are subsequently filled with about 1,600 pounds of raw material, which soon melts at a temperature of 2,500° F., caused by the intense flame of gas and air, which is deflected from the dome downward, the products of combustion passing out through a stack.

The glass gatherer receives his order for a specified size and shape for his article: and after obtaining a sample to guide his memory, takes his iron blowing tube, and collecting sufficient of the molten glass from the pot in the furnace, rolls it to and fro on a metal plate to produce a uniformity of distribution of the mass, which is then reheated in a furnace called a "glory-hole." He then turns it over to a glass blower, who takes the pipe and blows the article to approximately its final shape. It is then reheated and given definite form and finish by the most expert workman of all three. The tender glass must now be annealed or tempered to equalize the strains, otherwise the piece would break. It is then placed in kilns or tempering ovens, where it is first reheated and then gradually cooled.

The heavy uncut articles are then ready for the cutting operation, by which they lose considerable weight. In some cases the loss is one-third. The cutting operation really consists of three stages. The article is first roughed with sand and a steel grinding wheel. It is then smoothed by a stone cutting wheel, and is lastly finished by a wooden polishing wheel. A workman holds the article against the conical edge of a steel wheel secured to a shaft driven by belts and pulleys. Fine sharp clean sand and water are allowed to drip on the wheel from a cone-shaped bucket. The article is pressed against the rapidly rotating wheel, and is deeply scored or cut. The heaviest and principal lines in the pattern are roughed-in by these steel wheels and the sand. In order that all articles may stand level, the bottoms are ground on a horizontal grinding wheel, sand and water still being used. The rough article is now ready for the wet smoothing stones, which resemble steel wheels both as to size and edge, but no sand is used: these wheels follow the cuts that the steel wheels have made, and also cut in the finer lines of the pattern. The practically finished piece is now ready for the polisher, whose rouge-charged wheels are of wood, their size and edge being the same as those of the steel and stone wheels, and therefore adapted to follow every line with almost mathematical accuracy, which completes the process. While cut glass is made abroad, the examples lack shape and depth and uniformity of cut. For this reason the foreign trade in American cut glass is increasing every year.

Glass, Malleable. American glassmakers, since the beginning of the industry, have aimed to produce a glass that would have all the clearness and beauty of ordinary glass, and at the same time possess a toughness which would render it as little liable to fracture as many of the other manufactured articles of use and beauty. It is well known that the ancients discovered and made use of a process of manufacturing malleable glass; and in the glass-making world it has naturally been expected that it would be in the Old World that the process would sooner or later be reinvented. Louis Kauffeld, of Matthews, Ind., succeeded in 1903, after many years of endeavor, in producing a glass which will withstand extremely rough usage without breaking. The secret lies principally in the chemicals which are used and the proportion of ingredients which form the compound, although the furnaces and crucibles play an important part in the process.

The two chief things to be avoided in connection with the crucible are intense and prolonged heat from without and the corrosion of the raw materials within — two dangers of which nearly every glass-maker knows the ruinous effect. The effect of corrosion is readily proved by heating for a long time in a small crucible such substances as borax, red lead, or potassic or sodic carbonate. After a crucible has been in constant use for several months, and especially if it has contained flint or lead glass, the back and body will be found to be

covered with innumerable small dents, which have undoubtedly been formed by corrosion.

The complaint so commonly heard of specky glass arises from the presence in the glass of white particles of an infusible aluminate formed by the combination of the alkaline or metallic ingredients of the glass with the alumina of the crucible. If the corrosion becomes concentrated at one point and prolonged for a considerable period a breach is formed, through which the molten glass escapes into the furnace. Knowing the dangers that have to be encountered in this way. Mr. Kauffeld is extremely careful in the selection and preparation of the clay as well as in the construction of the crucibles. The finely sifted raw clay, on its arrival at his manufactory, is mixed with a proportion of burnt clay considerably coarser in grain, varying in amount from one ninth to one fifth of its weight. The coarser particles tend to bind the clay and render the finished crucible less liable to crack from variation of temperature. Various tests have been made of Kauffeld's methods. For instance, a chimney was placed in a pail of ice-water, and after having remained a sufficient length of time to become as cold as the water, was taken out and immediately placed on a lamp with the blaze turned as high as possible. The blaze on the wick was turned so as to flow directly on the chimney, and the smoke which collected on the chimney ran down with the water without injuring the chimney. Next a chimney was placed over a small gas stove containing clay bricks used in heating such stoves. The fire was turned on full, the chimney remaining on the bricks. The fire finally brought the temperature to such a stage that one side of the chimney was drawn in and dropped down, and no crack was shown in the glass; but for a slight roughness on the outside, the glass was as clear as when placed in the fire.

Another test which was made was to place cold water in the chimney and hold the same over a fire until the water boiled. A large bulb was blown from the glass and filled with about one pint of water. It was then placed over the fire and allowed to remain there until it had boiled dry without apparent effect on the glass. Four chimneys were taken from the packing room and dropped one by one into a pail of boiling water. The chimneys were then hastily shifted into a pail of cold water that had just been drawn from a well, and the glass was not broken.

Glass Manufactures in America, a great industry that began in America near Jamestown, Va., in 1608. The hope of sudden wealth from the discovery of gold and silver was doubtless the chief cause for the formation of the London Company and its first attempt to colonize Virginia. It was, however, a commercial venture with the hope of profit; and this company did not forget the possibilities that were near at hand in its search for what it believed would be greater ones in the near future. The vessel which carried Capt. Newport on his second voyage in 1608 brought out also eight Poles and Germans to make pitch, tar, glass, mills, and soap-ashes, and the first exports of manufactures from what is now the United States were the results of the trials made at the first furnace erected in this country. It is said the works were destroyed at the massacre in 1622.

In 1795, the time from which this sketch is to be made, there is no record of any glass-works in Virginia. In the census of 1810 Virginia does not appear as a glass-making State. In the census of 1820 a glass-works is reported in Brooke County. It made that year $20,000 worth of glass; had $12,000 capital; paid out $8,000 for wages and $12,000 for materials and contingent expenses, or exactly the value of the product. It employed 14 men and 12 boys in 1827. It is reported that glass decanters of great beauty were made at these works, and white-flint and green-glass wares were made that rivaled the foreign. At the Tariff Convention in 1831 there were two flint-furnaces, with 12 pots, reported in operation in Wellsburg, and one, with 6 pots, at Wheeling, Va. Two window-glass furnaces were also reported at Wheeling. In 1840 one glass-works is reported in Brooke County (the Wellsburg), and three in Ohio County (the Wheeling).

The first mention of a glass-works in Pennsylvania is found in a letter written by William Penn, in August 1683, to the Free Society of Traders. In this letter he alludes to their tannery, saw-mill, and glass-works. Where these works were located, or what kinds of glass they made, is not known. In 1795 there was doubtless some glass made in Pennsylvania. A glass-house was sold on 6 March 1800, to Joseph Roberts, Jr., James Rutlans, and James Rowland, for $2,333, and was again sold in 1833 to Dr. T. W. Dyott. In eastern Pennsylvania, prior to 1831, a number of attempts seem to have been made with but little success, and the works carried on by Dr. Dyott were evidently looked upon as being of national importance. It is stated that President Jackson visited this establishment, which in 1833 consumed 15,000 barrels of rosin for fuel. From 250 to 300 men and boys were constantly employed; five furnaces were operated, which used both wood, coal, and rosin, melted 8,000 pounds of batch a day, and produced about 1,200 tons of glass a year, which was blown into apothecaries' vials, bottles, and shop-furniture. Dr. Dyott failed in 1838, and the works passed into other hands, and at this time are operated in the manufacture of green glass, and have quite a reputation for the making of demijohns.

Of early glass making in western Pennsylvania full accounts are given. It is claimed that Albert Gallatin commenced the first glass-works there at his settlement of New Geneva, 90 miles south of Pittsburg, on the Monongahela River. It seems to be generally accepted that the works were started in 1797, and were used for the manufacture of window-glass. The furnace was a small one, with 8 pots, using wood as fuel and ashes for alkali. The glass-house was 40 by 40; three sides frame and one side stone. One man could lift the pots, while now it would require four men to lift the pots used in window-glass works. The title of the firm was Gallatin & Company, but was afterward changed to the New Geneva Glass Works. It is said that for a time this enterprise was exceeding profitable, there being but two or possibly three other window-glass works in the country, most of the glass for that purpose being brought from England. The glass was sold at $14 per box of 100 feet, but was doubtless of inferior quality. A works at New Geneva was reported as late as 1832.

THE MANUFACTURE OF BLOWN GLASS—LAMP CHIMNEYS

In 1796 Isaac Craig and James O'Hara erected the first glass-house in Pittsburg. It is claimed that these were the first works west of the mountains to make glass, and they are said to have started a month before those of Gallatin. These were the first works to use coal as a fuel, and were located at the south side of the Monongahela River, just above where it unites with the Allegheny to form the Ohio. The site, or part of it, has been continuously occupied as a glass-works. The use of coal was an innovation, and even as late as 1810 this fuel was not used in any of the glass-works in the United States other than those in Pittsburg. O'Hara and Craig were the pioneers in its use, and to them should be given the credit. As was the custom in window-glass factories in those days, one or more of the pots were used for the making of bottles, and among O'Hara's papers, found after his death, was a memorandum in his handwriting, stating: "To-day we made the first bottle, at a cost of $30,000."

As in all new enterprises, and particularly the making of glass, it is only men of perseverance and determination who succeed; and had not Craig and O'Hara been men of that character the venture would have fallen the first year. As a rule, the men who are secured from old-established glass factories are really not the best men; and not only did the early manufacturers suffer from a lack of experience, but also from the fact that their employees were not always capable of doing the work they were engaged to do. And it may be said that at the present time no new works, established in a location in which glass has not been made, can make a profit of any moment the first two or three years; and the first year must invariably be counted as a losing one. Craig wrote to Samuel Hodgson, of Philadelphia, 5 Aug. 1803:

> With respect to our glass manufacturing, the establishment has been attended with greater expense than we had estimated. This has been occasioned partly by very extensive buildings necessarily erected to accommodate a number of people employed in the manufacture, together with their families, and partly by the ignorance of some people in whose skill of that business we reposed too much confidence. Scarcity of some of the materials at the commencement of the manufacturing was also attended with considerable expense. We have, however, by perseverance and attention, brought the manufacture to comparative perfection. During the last blast, which commenced at the beginning of January, and continued six months, we made on an average [illegible] boxes a week of excellent window-glass, besides bottles and other hollow ware to the amount of one third the value of the window-glass, 8 by 10 selling at $13.50, 10 by 12 at $15, and other sizes in proportion.

In the fall of 1807, George Robinson, a carpenter, and Edward Ensell, an English glass worker, commenced the erection of a flint-glass works in Pittsburg, on the banks of the Monongahela. They appear, however, to have lacked capital, and were unable to finish the establishment, which, without being completed, was offered for sale. In August 1808 Thomas Bakewell and his friend, Robert Page, were induced to purchase this plant, on the representation of Ensell that he thoroughly understood the business. This was the beginning of the firm of Bakewell & Page, which by itself and successors continued in the manufacture of flint-glass until some time after the census of 1880. Bakewell experienced the trouble usual in a new business. His furnace was badly constructed; his workmen were not highly skilled, and would not permit the introduction of apprentices; and his materials were received from a distance at a time when transportation was difficult and expensive, pearl-ash and red lead coming over the mountains in wagons from Philadelphia, and pot-clay from Burlington, N. J. The sand was obtained near Pittsburg, but was yellowish, and up to that time had only been used for window-glass and bottles. The saltpetre came from the caves of Kentucky until 1825, when the supply was brought from Calcutta. These difficulties in time were overcome; good clay was procured from Holland, and purer materials were discovered, and Bakewell rebuilt his furnace on a better plan, competent workmen being either instructed or brought over from Europe. Through his energy and perseverance the works became eminently successful, and there is no doubt that Bakewell is entitled to the honor of erecting and operating the first flint-glass works in this country. The furnace built or completed in 1808 held six 20-inch pots; this was replaced in 1810 by a 10-pot furnace, and in 1814 another furnace of the same capacity was added to the works. The establishment was burned down in the great fire of 1845, but was immediately rebuilt.

Massachusetts has played a very important part in the production of glass, which was manufactured as early as 1639 at Salem. But, from all the records that exist, the history previous to the Revolution was one of failure. Shortly after the Revolution, Boston recommenced the manufacture of glass, which for many years had been one of the leading industries. The new enterprise, the Boston Crown-Glass Company, which was really the first successful glass-works in this country, was greatly helped by the liberal action of the State. In July 1787 Messrs. Whalley, Hunnewell, and others received from the legislature a charter conferring upon them the exclusive right to manufacture glass in Massachusetts for 15 years, and imposing a fine of $500 upon anyone infringing on this right. The capital stock was exempted from all taxes, and the workmen from all military duty. To counteract the effect of the bounty paid by England on the exportation of glass from the kingdom, a bounty was paid for every table of glass made. Owing to the many difficulties incident to the starting of a new industry, the operation of making glass did not commence until 1792. The company commenced with the manufacture of crown window-glass, and in 1798 produced glass to the value of $82,000 per annum. This concern was incorporated in 1809, and under the influence of the State bounty the proprietors were encouraged to continue their efforts, and became very successful. The glass was said to be superior to the imported, and well known throughout the United States as "Boston window-glass." These works were continued until 1826, when the company failed, from bad management. This early establishment led to the commencement of many others, but none of them could be considered successful. Many attempts have since been made in Massachusetts to establish the manufacture of window-glass. In 1860 a large establishment was erected for the manufacture of sheet window-glass, but its operation proved unprofitable, and at this time there is only one window-glass works in the State, located in Berkshire County.

The manufacture of flint-glass grew out of the Essex Street works. Thomas Caines, an employee there, was also a skilful blower and

metal mixer. He prevailed upon the management to allow him to build a small 6-pot furnace in a part of their works at South Boston. This furnace was fully employed during the War of 1812, and was the beginning of the flint-glass industry in Massachusetts; but it was compelled to cease work, and although several attempts were made to operate it between 1820 and 1840, they all failed. About the time this furnace was started, the Porcelain and Glass Manufacturing Company built a factory at East Cambridge. The furnace was a small one, containing 6 pots. Workmen were brought from abroad, but it proved a failure. The plant in 1815 was leased to a firm of workmen, Emmet, Fisher & Flowers; but they failed to agree, and in 1817 the Porcelain Company sold the property at auction to the New England Glass Company. This was the beginning of one of the most successful glass companies in this country. The works, when they commenced, had a small 6-pot furnace, the pots holding about 600 pounds; 40 hands were employed, and they produced glass to the value of $40,000. It was really the foundation of the flint-glass industry in the United States. The management was broad and liberal from the beginning; for 50 years they led in the production of flint and colored glass of all varieties. Workmen were brought from abroad, and every means employed that capital and skill could compass to produce results equal to anything in the world. In 1865, which was probably the highest point reached in their history, they operated 5 furnaces of 10 pots each, each pot holding 2,000 pounds; 500 hands were employed, and glass to the value of $500,000 was produced yearly. The influence of the New England Glass Works has been felt all over the land, as many of their employees and managers have been the means of establishing the industry in other parts of the country. Fine blown, cut, and pressed glass were made in great variety. The works are not now in existence.

When the western manufacturer commenced to make lime-glass with bicarbonate of soda and lime, in place of lead and pearl-ash, the thought in the minds of the management of the New England Works was that its success would be only temporary, and they failed to meet the changed condition. A very large proportion of their production at this time was pressed glass, and for several years, in the attempt to meet the competition of the cheap products of the western manufacturers with their more costly products, the works were run at a loss, which amounted during the last year they operated to more than $40,000. In 1888 they ceased operation.

In 1825 a plant was established at Sandwich, commencing in a small way, with one 8-pot furnace, and melted 7,000 pounds of glass. In 1865 it had been increased to 4 furnaces, 10 pots each, and a melting capacity of 100,000 pounds weekly. It was in these works that the modern invention of pressing glass was first successfully introduced, in 1827. In 1888, after several years of financial loss, the company suspended operation. They had built up quite a town at Sandwich, and up to 1865 had been prosperous and successful, employing for 63 years a large number of people, and making a fine line of cut, blown, colored, and pressed glass.

During the period in which these two Massachusetts factories were in existence they were in the lead, and while a number of others had been established, none had reached the success of these two noted works, which are now only a part of the record. Quite recently an attempt has been made to operate one of the furnaces at Sandwich, the success of which is yet to be demonstrated. At this time there are only four flint-furnaces operated in Massachusetts, two of them being at New Bedford, one at Somerville, and one at Sandwich. There are, besides, the window and part-plate works at Berkshire. So that Massachusetts, that in 1860 led the flint-glass industry in this country, has almost ceased to be a factor at this time.

Maryland was quite an important State in the early production of glass, and the attention of Congress was called to the value of the industry by John Frederick Amelung, who petitioned Congress to extend its patronage to his works at New Bremen. A motion was made in Congress to loan him not exceeding $8,000, on his giving security for its repayment. The motion was debated for several days, during which was brought out the fact that Amelung had spent over $100,000, and brought over from abroad over 200 workmen, in his attempts to establish the industry. The motion was defeated. In 1794 Amelung presented a petition for an increase of duties. These works appear to have been built at Fredericktown, but were afterward moved to Baltimore. They were not a success, and it is probable he crossed the mountains and helped to start the flint-works at Pittsburg. A plant was established for the making of window-glass in 1790, known as the Baltimore Glass Works. These are the window-glass works operated by Baker Brothers until quite recently. They have operated them since 1852. Maryland, however, since that period, has been quite a glass State. Window-glass and green and flint bottles have been made to a greater or less extent.

One of the earliest glass-works in this country was located at Allowaystown, in Salem County, N. J. It was the beginning of the glass industry in that State, and was built about the year 1760 by a German named Wister, who carried on the works until his failure in 1775. The workmen then went to Glassboro, and established the industry there. Plenty of pine-wood for fuel was found in this locality, and a very fair grade of sand, which was good enough for bottles, jars, vials, and the common kinds of green glass made by them. Glass making has been carried on at this place ever since that time. The first establishment commenced with a 6-pot furnace, but gradually extended until a town surrounded it. In 1870 there were factories at 37 different localities. Many of them ran for only a short period. The cheapness of wood and sand no doubt led to the building of many, and the fact that expensive buildings were not required, most of them being frame structures. With the exception of a flint-works at Jersey City and one at Camden, the glass made in New Jersey was bottles, jars, vials, and window-glass.

In New York State large quantities of glassware have been made, and some of the works have had a national reputation. In January 1785 Leonard de Neufville and his associates, the proprietors of a glass factory located 10 miles from Albany, at Dowesborough, in the

midst of a well-wooded pine forest, applied to the legislature for aid in the undertaking, giving as a reason that $150,000 annually was sent abroad for glass. In 1793 the legislature of New York voted to loan them $3,000 for eight years without interest, and five years at 5 per cent, but by this time the works had passed out of the De Neufville family. The history of glass making in New York State shows that up to 1850 there had not been much headway made in establishing it on a permanently successful basis. Many factories were started, but ran for only a short time, and none of those in operation in 1850 are now in existence.

In 1820 some workmen left the New England Glass Works at East Cambridge and built a factory in New York city, under the firm name of Fisher & Gilland; but in 1823 the partnership was dissolved, and Gilland removed to Brooklyn, where he established what were known as the South Ferry Flint-Glass Works. Gilland up to 1850 was evidently very successful. He had the reputation of making the finest flint-glass made in this country, and at the London Exhibition in 1851 took a medal for the best flint-glass on exhibition. He afterward failed, and the works are not now in existence.

Like other industries in the United States, the history of the glass business was, between 1850 and 1860, one of great depression. Fine glass was made in New England and in New York and in one or two factories in Pittsburg, but the bulk of the product was of poor quality, and the window-glass did not in any way measure up to the imported glass. During this period, however, a great impetus was given to the flint-glass business by the making of coal-oil from coal and the later discovery of petroleum. The demand for lamps and lamp-chimneys was very extensive. One of the first to make a specialty of glass for lighting purposes was Christopher Dorflinger, who started with a capital of $1,000 in 1852, in Concord Street, Brooklyn. The furnace held 5 small pots, and was afterward increased to hold 7, until in 1861 he was operating 4 furnaces. The first year his sales amounted to $30,000, and he employed 85 people. When he left Brooklyn in 1865 his sales amounted to $300,000. The factories increased in Brooklyn, from 1858 to 1865, from 2 to 15, mostly making the same class of ware, which was principally for lighting purposes — lamp-chimneys, gas-globes, and lamps. In 1865 Dorflinger moved to White Mills, and established one of the best-known and largest of the manufactories of cut glass.

In 1860, from the best records we can get, the product of the glass factories did not exceed $7,000,000. 1861 and 1862 were off years. The excitement incident to the commencement of the War produced great depression, but from 1862 until 1870 the increase in production was very great, and the census showed 154 establishments, with 15,367 employees, producing glass to the value of $16,470,507, with a capital invested of $[illegible]42. It was during this decade that great improvements were made in the making of pressed glass. The modern discovery of pressing glass was an American invention, and the credit is given to the Sandwich Glass Company, which, at the solicitation of a carpenter, in 1827 made a mold to press an article he wanted made. After that the mold increased rapidly in favor, but was used only for the commoner class of goods for many years, until the New England Glass Company, by a series of expensive molds, had produced some very fine effects in pressed glass. The triumphs of pressed glass in this country, however, came from Pittsburg. James B. Lyons, of the O'Hara Glass Works, Pittsburg, made for many years pressed glass only, and in 1867 made an exhibit at the Paris Exposition, and took the first prize for fine pressed glassware. Goblets and wine-glasses were made almost as fine and delicate as those made by the old mode of blowing and cutting. Prior to 1864 the pressed glass was either made of flint-glass, the ingredients of which were the best of sand, pearl-ash, refined saltpetre, and oxide of lead, and was a very good crystal glass, or from what was then known as German flint or lime glass, the ingredients of which were soda-ash, lime, nitrate of soda, and sand. This latter made a very inferior glass, apt to crack, and very poor in appearance. It was used principally in common tumblers and some lamp-chimneys.

In the winter of 1864, William Leighton, Sr., of the firm of Hobbs, Brockunier & Company, of Wheeling, made a series of experiments with bicarbonate of soda, with pure sand, lime, and refined nitrate of soda, and produced a very clear, brilliant glass, at a cost for the batch of not more than one third that of the lead-glass or flint batch. The result was a complete revolution in the pressed-glass business. It was impossible for the manufacturer making flint-glass to compete, and the result was that all had to adapt themselves to the change, and some were driven out of the business. Up to 1870 there had been very little change in the furnaces, which were mostly the old-fashioned type of round furnace, with the coal fired over the bench, or the Frisbie bucket-teaser, where the coal was pushed up from below. But the close competition and the desire for increased production led to the effort to get better results from the furnaces, and after 1870 larger furnaces were built, into which, by a series of flues, hot air was introduced to the combustion-chamber, and much greater heat secured with much less fuel. Many of the furnaces also hold from 13 to 15 pots, and many of the pots each hold two tons of glass.

The Centennial Exhibition held in Philadelphia gave a large impetus to so many industries. One of the great attractions was the glass works operated by Gillinder & Sons, of Philadelphia. It was a complete establishment, showing the processes of melting, blowing, pressing, cutting, etching, and annealing. The furnace held six pots and melted double the amount of glass made by the first flint-glass works operated in this country by Bakewell & Page, in 1808. This was the first time anything of this kind was attempted in an international exhibition. The product was sold as souvenirs, and realized $96,000. Over $14,000 was paid to the Centennial Board of Finance as commission on the sales.

At the close of 1880 the glass trade was in a very prosperous condition. Prices were good, and the outlook looked promising for the future; and it is from this period we must date the wonderful progress of plate-glass making in this country. In 1880 there were but four plate-glass works in this country, and only three in operation. They were located at New Albany,

Ind., Jeffersonville, Ind., Crystal City, Mo., and Louisville, Ky., the latter plant being idle. The first attempt to make plate-glass was made in 1852, when Tilton, Pepper & Scudder started a factory at Williamsburg, L. I. The works were under the management of Cuthbert Dixon, a plate-glass worker from the Thames Plate-Glass Works, London, England. They produced a good quality of rough plate, but, owing to the ruinous competition of the English and German manufacturers, at the end of two years they were compelled to close. There is some dispute as to where the first plate-glass was made in the United States, but there are existing proofs that the Williamsburg works were the first, based upon the records found in an old diary of the late William S. Dixon, of Pittsburg, who was employed there as pot maker, his father being the manager.

Attempts were made to make plate-glass at Cheshire, Mass., Lenox Furnace, Mass., and at Greenpoint, L. I., previous to 1860. There are records of polished plate-glass being made at Lenox in 1865, but it was not continued. The successful founder of the plate-glass industry in this country is James B. Ford, of Pittsburg. In the year 1869 Ford conceived the idea of making polished plate-glass, and with this in view visited the works at Lenox, gathered what information he could from the workmen who had been imported from abroad, and returned to New Albany with the determination to make plate-glass. Machinery for this purpose was imported, and the new plant was speedily successful so far as the production of plate-glass was concerned; but, like all new enterprises of the kind, it was not profitable, and in 1872 Ford withdrew. The factory was continued by William C. de Pauw until his death, and afterward by his heirs. He demonstrated, after a hard struggle, that polished plate-glass could be made here at a profit. Mr. Ford afterward built a factory at Louisville, Ky. It had two 12-pot furnaces and was equipped with the old-style French machinery. He ran these works for two years and sold out, removing to Jeffersonville, Ind., where he built a plant that he operated until he moved to Creighton, Pa., in 1881. Shortly after the building of the New Albany plant, E. B. Ward, of Detroit, and others, attracted by a very extensive deposit of sand of fine quality, originated the American Plate-Glass Company, with a capital stock of $250,000, and began in 1872 the erection of works at Crystal City, Mo. The capitalization was increased in 1874 to $500,000, and the works were operated until 1876, producing some glass of good quality; but, owing to lack of experience, the management failed to make a profit. In 1877 the works were reorganized, new capital was secured, A. E. Hitchcock, of St. Louis, president of the old company, continuing in charge. G. F. Neal, a practical plate-glass manager, took charge of the works, and a Siemens furnace was erected. The works have been largely increased, and plate-glass is made in Crystal City equal to any found in Europe. This was the condition of the plate-glass business when Ford built the Creighton Works in the midst of a rich gas-coal country. He built a factory with a capacity of 70,000 square feet per month. It was equipped with two 16-pot furnaces, 8 grinding and 16 polishing machines. This was really the first plate-glass works in this country that paid for the large investment required in its establishment.

While the success of these works was very largely helped by the experience that Ford had gained from his previous ventures, a new factor was introduced that had never been used in the making of plate-glass before. This was natural gas, which it was found could be used as a fuel. The Rochester Tumbler Works had used it in their leers, and partially in their furnaces, as far back as 1875; but not having sufficient for the furnaces, it was not a success. At about the time Mr. Ford was starting at Creighton, wells had been drilled that promised inexhaustible quantities of the new fuel. For glass making it is impossible to conceive of a more perfect fuel — no labor required for firemen, no dirt, no ashes, and a uniform heat, or just what was required. Natural gas was a great factor in the success of these works, which were sold by Ford to the Pittsburg Plate-Glass Company, who enlarged them in 1883, and increased the output from 70,000 square feet to 110,000 square feet finished product. Having a great desire to own and operate his own works, Ford, in 1884, commenced the building of a plant at Tarentum, Pa., with a capacity of 150,000 square feet per month. Before it was completed the Pittsburg Plate-Glass Company made him an offer, which he accepted, and the Tarentum plant became part of the Pittsburg Plate-Glass Works. The success of their plants resulted in the building of plate-glass works at Butler, Pa., in 1886, and at Cochran Station, Pa., in 1889.

Natural gas had been discovered in Indiana. A large plant was built at Kokomo, Ind., under the name of the Diamond Plate-Glass Company. The gas being in abundance, this same company erected another large factory 20 miles away, at Elwood, in 1891; and the extensive works at Charleroi and at Irwin, Pa., were erected the same year. The Pittsburg Plate-Glass Company in 1887 commenced the erection of what are now the largest plate-glass works in the world. The company bought 480 acres of land, and a town was laid out, and named Ford City, in honor of J. B. Ford, who is one of the largest stockholders. Under his personal supervision the works were built, which have a monthly capacity of 400,000 square feet. In 1891 the De Pauw Plate-Glass Company built a small plant at Alexandria, in the heart of the gas belt; but the panic of 1893 caused its suspension, and it has not been operated since.

The works mentioned have an aggregate monthly capacity of 1,785,000 square feet, or an annual maximum production of 21,420,000 square feet. In 1894 a movement was made by some of the companies for self-preservation, which resulted in the outright purchase by the Pittsburg Plate-Glass Works of all the plate-glass works in the United States, with the exception of those at Butler and Irwin Station and the De Pauw plants of Indiana.

The total number of furnaces is 43 of 20 pots each, and 2 of 16 pots each. Of this number there are in operation at this time only 23 furnaces, containing 460 pots. Plates of glass are made containing 180 square feet, or, say 12 by 15 feet. The success of the plate-glass business, which really dates back only 20 years, is one of the wonders of our age. Much credit must be given to J. B. Ford, and especially when we consider that when the factory at Creighton was

started he was over 70 years of age, and had to impress upon the capitalists his own faith that the business could be made to pay. So far as Pennsylvania was concerned it was an entirely new venture, the census of 1880 showing that no plate-glass was then made in Pennsylvania.

From the year 1880 may be dated also the great success of window-glass making. Prior to this time, with few exceptions, the old furnaces and flattening-ovens that had been in use for 50 years were still prevailing. Fully 25 per cent of the window-glass used in this country was imported. For many years the workmen have been organized into a union, which not only takes in the blowers, but the gatherers, flatteners, and cutters; these last two being practically unskilled labor, and paid as such in European countries. Then, to mend matters and make competition worse, the manufacturers of Belgium and England had adopted what is known as the tank-furnace; no pots were required, a more uniform quality of glass could be depended upon, and a much larger production. James Chambers, of Pittsburg, who had succeeded his father in the manufacture of window-glass, was in 1887 operating 4 furnaces with 36 pots, using natural gas in his furnace and flattening-ovens. He had the improved flattening-ovens, but he came to the conclusion that something had to be done to put the window-glass business upon a better basis. He made a trip to Europe, obtained all the information possible, came back to Pittsburg and organized the Chambers & McKee Company, and, as president, planned, built, and operated the plant at a place on the Pennsylvania Railroad, 27 miles east of Pittsburg, called Jeanette. The foundation of the tanks was laid in 1888, and in the spring of 1889 they commenced making glass. Glass workers and manufacturers all over the country, with few exceptions, had predicted that the tanks would be a failure, and that window-glass could not be made that way; but the tanks were a success from the first.

Owing to financial disagreement, Chambers withdrew from the Chambers & McKee Company, and in 1892 formed a company and erected a factory at New Kensington, 10 miles from Pittsburg, on the Allegheny Valley Railroad, and built two continuous tanks that are said to be the largest in the world. They are 25 feet 6 inches wide, 130 feet long, inside measure; each furnace will hold 1,000 tons of molten glass, and has a melting capacity of 35 tons, turning out 600 boxes of single and 300 boxes of double strength every 24 hours. This is said to be the largest and most complete establishment in the world for the manufacture of window-glass.

The discovery of natural gas, and its application to the glass-furnaces, led to a very great increase in the building of flint- and green-glass works. To-day probably the largest flint-bottle works in the world are those of the Illinois Glass Works at Alton, where 4,500 people are employed. Here was blown in 1903 the largest glass bottle in the world. The next largest bottle works are those of Whitall, Tatum & Company, located at Millville, N. J. They have 13 flint-furnaces, in addition to 5 green-glass furnaces and a green-glass tank, and employ from 1,500 to 1,000 employees, according to the demand for their goods. This business has been principally built up since 1860. The Rochester Tumbler Company, at Rochester, Pa., was organized in 1872, and commenced making glass in July of the same year. They commenced with one 10-pot furnace and 90 employees, making a specialty of tumblers, and with a capacity of 12,000 dozen per week. At present they operate 7 furnaces with 88 pots, with a capacity of 75,000 dozen per week, or 150,000 tumblers each day. The melting capacity of the furnaces is 120 tons of sand per week. The pots are very large, and over 1,000 hands are employed. When they first commenced they made only common tumblers, but now they make every kind of tumblers, with a cutting, engraving, and decorating department. The works cover over seven acres of ground. They make their own barrels, boxes, and machinery, and almost everything used for the manufacture of glass. All the fuel used is natural gas. They do some export trade — probably more than any other concern in this country — and without question have the largest plant in the world making a specialty of tumblers.

The discovery of natural gas was the means of largely stimulating the erection of flint-glass furnaces, and many small towns offered land and a bonus in money to have a glass-works established in their boundaries. By this means many works were started by parties who had little knowledge of the business, so that the business was largely overdone, and prices in 1891 were such that little or no profit could be made. Labor was high, and, in view of there being so much demand for it, was aggressive and unreasonable in its claims, being backed up by its labor organizations. A number of manufacturers met together and formed a stock company under the name of the United States Glass Company, which company bought up 15 of the largest and most complete press manufacturers in the country, located in Pennsylvania, Ohio, and West Virginia. The 15 establishments had a capacity of 29 furnaces. The company afterward erected a plant at Gas City, Ind., with three 15-pot furnaces, to get the benefit of the natural gas fuel. The capital stock of the company was $4,158,100, $640,000 of which is preferred and $3,518,100 common stock. The first year of its existence as a corporation the sales amounted to very nearly $3,000,000. With a view of consolidating the plants the company bought 500 acres of land on the Monongahela River adjoining McKeesport, Pa., and erected two 15-pot furnaces. It is without question the largest flint-glass works in the world, and is almost able to supply this country with table-glass, if all the furnaces were in full operation. Quite a number of flint-glass works are operated in the making of glass for lighting purposes — arc globes, gas-globes, and shades for electric lighting. There are six leading companies making these goods, four of them located in Philadelphia, one at Monaca, Pa., and one at Brooklyn, N. Y.

Gillinder & Sons, of Philadelphia, were the first of these works established, and operations were commenced in 1861 by William T. Gillinder, the father of the present owners. Their works have two furnaces, with 23 pots, and have a capacity of production to the amount of $400,000 per annum. It is impossible to continue further to enumerate special plants, but so far as glass making is concerned America is practically in-

dependent. We have sand in almost every State of the Union fit to make glass. The sand of Massachusetts, Pennsylvania, and Missouri is equal to, if not better, than any other sand in the known world. Soda-ash and other chemicals are being made, and when the beet-sugar industry is fully established we shall be able to get pearl-ash from the ashes of the beet, so that it will not be necessary to import our potash from Germany. We have fire-clay for furnaces, which is found in many States of the Union, notably in New Jersey, Ohio, Pennsylvania, and Missouri. The pot-clay found near St. Louis, Mo., has been used for more than 40 years. It is a very superior clay, and for the making of glass-house pots is unsurpassed. It is capable of resisting a very high degree of heat, and will stand the changes of temperature much better than the most celebrated clays of Europe.

In the preparation of this article I have been aided very much in the early records by the 'History of Glass Making in the United States,' prepared by Joseph D. Weeks; and for information in regard to the various improvements in furnaces and leers, by H. L. Dixon, of Pittsburg, who has been identified with the building of many of the improved furnaces that have taken the place of the old furnaces. See GLASS.

JAMES GILLINDER,
Franklin Flint-Glass Works, Philadelphia.

The following statistics from the United States census report for 1900 will be found valuable for comparison with the figures heretofore given :

COMPARATIVE SUMMARY OF THE GLASS TRADE, 1850 TO 1900.

	DATE OF CENSUS			
	1900	1890	1870	1850
Number of establishments	355	294	201	94
Capital	$61,423,903	$40,966,850	$14,111,642	$3,402,350
Salaried officials, clerks, etc., number	2,268	[2] 1,095	(3)	(3)
Salaries	$2,792,376	[2] $1,232,561	(3)	(3)
Wage-earners, average number	52,818	44,892	15,822	5,668
Total wages	$27,084,710	$20,885,961	$7,846,425	$2,094,576
Men, 16 years and over	42,173	36,064	11,505	5,571
Wages	$24,901,233	$19,546,351	(3)	(3)
Women, 16 years and over	3,529	1,885	715	97
Wages	$840,001	$332,245	(3)	(3)
Children, under 16 years	7,116	6,943	3,602	(3)
Wages	$1,343,476	$1,007,365	(3)	(3)
Miscellaneous expenses	$3,588,641	$2,267,696	(4)	(4)
Cost of materials used	$16,731,009	$12,140,985	$6,133,168	$1,556,833
Value of products	$56,539,712	$41,051,004	$19,235,862	$4,641,676

[2] Includes proprietors and firm members, with their salaries; number only reported in 1900, but not included in this table. [3] Not reported separately. [4] Not reported.

RANK OF STATES ACCORDING TO VALUE OF PRODUCTS, 1880 TO 1900.

STATES	Rank			Value of Products		
	1900	1890	1880	1900	1890	1880

[2] Included in "all other" glass and glassware imported previous to 1884.
[3] Included in "unsilvered cylinder and crown glass, polished" previous to 1885.
[4] Not separately reported previous to 1886.
[5] Included in "all other" glass and glassware exported previous to 1884.

FLINT OR GLASS SPONGES

Glass Painting. See GLASS STAINING.

Glass Snail, one of the minute, grass-haunting, hyaline land-snails of the genus *Vitrina.*

Glass-snake, or **Joint-snake,** a limbless, snake-like lizard of the genus *Ophisaurus* (family *Anguidæ*), which takes its name from the brittleness of the tail, which is more than twice the length of the body, and whose vertebræ are so slightly connected, that a part or all of the tail will easily break off, or may be cast off; but the lost part is quickly renewed. The head is very lizard-like. No vestige remains of limbs except two little spikes near the vent; the body is serpentiform, but the stiff armor of scales prevents the graceful movements of a serpent. The glass-snake (*O. pallasi*) of southeastern Europe may exceed a yard in length, and dwells in bushy districts where it can hide under leaves and sand, and catch snails and small animals. A smaller species (*O. ventralis*) is found in the Mississippi Valley and the southern United States. It is greenish-gray or brownish; sides largely yellow, with narrow black streaks; but the coloration varies greatly, especially in western specimens. Several nearly related species inhabit Central America. These lizards are rapacious and devour great numbers of ground-keeping insects and crayfish. They breed by means of eggs hidden in loose soil or leaves; and are of slow growth. They are said to be easily tamed, and to show intelligence.

Glass-sponges, certain silicious sponges are so-called from the fact that the fibres or spicules composing their solid framework or skeleton is like finely spun glass. The glass-sponges, such as the Venus' flower-basket (*Euplectella*) and allied forms, live in fine sandy mud in deep water. The *Euplectella* inhabits the ocean around the Philippine Islands in from 10 to 20 fathoms. It forms a hollow cylinder or basket-work of spicules, enlarging at the top, which is broad and a little convex; it grows rooted in the sandy mud, anchored by its long glass spikes, which at the extremity end in anchor-like hooks. A number of similar but shorter, more dense sponges (*Holtenia*, etc.) live at great depths in the Atlantic, one kind occurring in shallower water (100 fathoms) in the Gulf of Maine. The glass-sponge of the Japanese seas is *Hyalonema*, in which the stem is twisted, composed of fibres, like spun glass, while the body of the sponge is long and slender; it grows nearly three feet in length. These glass-sponges, with the spicules having three crossed axes, or six threads radiating from a common point, are grouped in a family (*Hexactinellidæ*). The efferent canals are loosely meshed, while the digestive chambers (ampullæ) are large and barrel-shaped.

Glass Staining and Glass Painting, the art of producing pictures on glass with vitrifiable colors; but a common extension of the meaning is to include all the make and design of ornamental glass windows. Originally there was but one method of making these, and that was to produce the pattern in outline with frames, into the grooves of which pieces of colored glass or of stained glass were fitted. In the Moslem East these frames were of plaster, or rarely of marble slabs pierced with openings. In Europe, since the 12th century, these frames have been of lead, rolled or drawn into what are called *cames*, that is, bars of an I section, the two grooves holding the glass firmly. Modern chemistry has so improved the art of glass staining, that large pictures may now be produced on single sheets of glass, but nowhere have such pictures been successful in an artistic sense. In the original painted glass windows the pictures resembled tables of mosaic work, in which there was no attempt at shading or modification of the tone. What is perhaps the earliest known application of colored glass to window decoration, in Europe, is that in the monastery of Tegernsee, in Upper Bavaria, which was secularized in 1802, and is now a private residence. The windows of this structure, executed in the latter half of the 10th century, like all the first attempts, were only tasteful arrangements of colored glass in a translucent mosaic.

In the early part of the 13th century the mosaic patterns gave way to more elaborate designs, not only in beautiful Arabesques, but even in pictorial composition. In all these the figures were composed of pieces of colored glass combined with marvelous skill and taste. The work of shading and making so-called half-tints was not attempted; but an effect not dissimilar was got by painting in opaque pigment upon the glass and breaking up this painted surface into patchings and spots, as when an artist draws in crayon or charcoal. The finest English examples of this early mosaic work are to be found in the cathedrals of Canterbury, Salisbury and Lincoln. In the 14th century the art of shading was advanced by removing certain portions of the colored surface. The first period of the art reached the culminating point in the 15th century, but with the passing of Gothic architecture, glass painting lost its artistic spirit. Subjects in which were arranged a multitude of personages with all the elaborate artifices of pictorial composition; buildings showing complex linear perspective; foreshortened figures; the play of light and shade — all this was attempted to be exhibited in painted windows. It soon became apparent that the true art was lost, and though windows continued to be painted, only a few artists acquired celebrity. Perhaps the best examples of the 15th century period are the windows of the Cologne cathedral.

About 1600, Bernhard von Linge, an artist from the Netherlands, residing in England, and who may be considered the father of the modern art of glass staining, established a school in London, whose influence is evident in the work of the present day. Francis Eginton (1737–1805), a native of England, accomplished much to restore the art during the 18th century. Among his numerous works, all of which are remarkable for brilliancy of coloring and delicacy of execution, are: 'The Banquet of the Queen of Sheba' (a copy from Hamilton); two 'Resurrections' (from Sir Joshua Reynolds); 'Christ Bearing the Cross' (from Morales); and 'The Soul of a Child' (from Peters). Other famous artists of this period were Jouffrey and Baumgartner. The Renaissance in glass painting was contemporaneous with the revival of Gothic architecture in the beginning of the 19th century. Four German artists, Mohn, Scheinert, Ligm and Frank, were

prominent as glass stainers during the century. In 1850, through the generous assistance of King Louis of Bavaria, a school was founded at Munich under the direction of Gartner and Hess, the latter a well-known historical painter, which obtained a world-wide celebrity. Still, however, the purists in Gothic art, and those who were most concerned in the Gothic Revival would have none of this glass of the early 19th century. It was seen that the smooth and clear modern glass would never do; and rough, partly opaque, flawed and bubbled glass was prepared on purpose. This material, known as "antique" and as "cathedral" glass, and by other names, allowed of a far more decorative effect.

In 1902 the chief centres of the art in Europe were at Birmingham, England; Edinburgh, Scotland; Paris and Sèvres, France, and Munich, Metz and Nuremberg in Germany.

Not until comparatively late in the 19th century did the art of glass staining obtain a place in the United States. Only a few years ago Americans were seemingly content with imported windows, or with poor imitations made here. In both cases the windows were but copies of mediæval work, seldom equaling the originals, and never showing an advance, either in artistic qualities or improvement of method over the windows of the Middle Ages. Several artists and some makers of church furniture began making fine windows, and to-day largely through their efforts American colored glass-windows have become celebrated for their color values and their color relations. John La Farge, Louis C. Tiffany and other American artists in glass painting and glass staining took up the art where the mediævalists stopped, in the study of the inherent properties of the glass, both in their color and texture, in order to obtain in the glass itself light and shade, through depth and irregularity of color, in union with inequality of surface. In this way they sought to avoid the dullness, opacity and thinness which invariably accompany the use of paint, and are marked characteristics of European glass work. It was an American idea to make glass in lumps and chip it into flakes, to corrugate it, to blow it into shapes, or to pull molten glass out of shape. By such means the artist has succeeded in obtaining effects in this obstinate material which were deemed impossible. There was introduced a few years since the use of opalescent glass, the plating of glass over glass and developing the mosaic system, substituting it for glass painting. Churches, houses, hotels, and theatres are now decorated by the mosaic stained glass which is largely a product of New York studios. Upward of $3,000,000 was invested in 1902 in the stained glass industry in the United States.

Glasse, glas, **Hannah,** English writer. She was the author of ‹The Art of Cookery› (1747), a work whose claim to remembrance has depended chiefly on the mistaken reference to it of the proverbial "First catch your hare." In the fourth edition (1770) she is described as a habit-maker in Tavistock Street, Covent Garden.

Glauberite, glâ'bėr-īt, a mineral having the formula $Na_2SO_4.CaSO_4$, and crystallizing in the monoclinic system, usually in tabular forms. It is commonly pale yellow or gray in color, with a white streak. It has a hardness of from 2.5 to 3, and a specific gravity of from 2.7 to 2.85. Glauberite occurs in connection with rock salt in various parts of the world. In the United States is found at Borax Lake, San Bernardino County, Cal., and in tabular crystals in the Rio Verde Valley, Arizona.

Glauber's (glow'bėrz) **Salt,** sulphate of sodium, Na_2SO_4, so called from the German chemist, Glauber, who prepared it in 1658 by distillation of common salt with sulphuric acid, named it "sal mirabilis," identified it with the salt of a beneficial mineral water, and urged its good qualities. It occurs throughout Europe, especially at Carlsbad and Seidlitz, and in North America, notably at the Great Salt Lake in Utah. It forms oblique prisms which effloresce on the soil or on rocks. These are of a gray or yellow color, earthy, but transparent and vitreous when newly broken. It is readily soluble in water, and when heated or exposed to the air melts in its water of crystallization. Its chief use is in the manufacture of glass and sodium carbonate.

Glaucine, glâ'sĭn, an alkaloid contained in the leaves of *Glaucium flavum*, a sort of poppy. The leaves are macerated with acetic acid; the juice is pressed out, boiled, filtered and the filtrate is treated with lead nitrate, which precipitates lead fumarate. The filtrate is treated with H_2S, then the glaucine is precipitated with tannin, and the precipitate decomposed by chalk. Glaucine crystallizes out of water in small scales, is easily soluble in alcohol and ether, and forms crystalline salts.

Glaucodot, glâ'kō-dŏt, or **Glaucodote,** an orthorhombic, grayish, tin-white mineral of metallic lustre and black streak; hardness, 5; specific gravity, 6. Composition: Sulphur, 19.4; arsenic, 45.5; cobalt, 23.8; iron, 11.3. It occurs in chlorite slate in the province of Huasco in Chile, also in fine crystals in Sweden.

Glaucoma, glâ-kō'ma, a diseased condition of the eyeball characterized bv a retention of the fluids within its cavity. As the fluids accumulate, pressure is exerted on the delicate lining, with resulting injury or destruction of sight. It is due to any causes operating so as to close the place of exit for the fluids of the inner chamber of the eyes. See EYE, DISEASES OF.

Glau'conite, an amorphous green opaque mineral, like earthy chlorite, with a dull or glistening lustre. It is a hydrous silicate of iron and potassium, averaging: Silica, 49.3; alumina, 3.6; sesquioxide of iron, 22.7; protoxide of iron, 6.3; potash, 8.3, and water, 9.6. Its hardness is 2, and its specific gravity about 2.3. There are two varieties of it; the one the green earth of cavities in eruptive rocks, the other the green grains in greensand formation, or anything similar.

Glaucophane, glâ'ko-fān, a mineral of the amphibole group, crystallizing in the monoclinic system, and closely resembling amphibole in form. It is a silicate of aluminum, sodium, iron and magnesium, with variable proportions of the two latter metals. It is blue or gray in color, translucent with a vitreous lustre, and has a hardness of from 6 to 6.5, and a specific gravity of about 3.10. Glaucophane occurs in certain crystalline and mica schists, and is found associated with mica, garnet, epidote and dial-

lage. In the United States it occurs chiefly along the Coast Ranges of California.

Glaucus, glâ'kŭs, the name of several personages in Greek legend. (1) A sea-god, who was at first only a fisherman, and whose oracles were highly prized by fishermen, according to the legends. (2) The son of Hippolochus and grandson of Bellerophon. He assisted Priam in the Trojan war, and was foolish enough to exchange his golden armor for the iron suit of Diomed. He displayed much courage, but was killed by Ajax. (3) The son of Sisyphus, king of Corinth, by Merope, daughter of Atlas, and born in Potnia, Bœotia. He wished to make his mares swifter than others, for the purpose of vexing Venus, and Venus inspired the animals with such fury that they tore Glaucus to pieces as he returned from the games which had been celebrated by Adrastus in honor of his father. (4) The son of Minos II., and Pasiphæ, smothered in a cask of honey, and miraculously brought to life, by an herb sent by Polyidus the soothsayer.

Glaze (ceramic), a vitrified coating which gives to earthen-ware or porcelain its brilliance and impermeability.

Glazes are of three classes: the glaze proper (Fr. *couverte*), the soft glaze (Fr. *vernis*), and the enamel or opaque glaze (Fr. *émail*). The glaze proper is a silicate of calcium, potassium and aluminum, and is composed of feldspar, chalk or whiting, kaolin and quartz. It is applied either to the clay ware (Chinese) or to the soft burned biscuit (modern); the whole piece is then burned to a high temperature (about 1,500° C.). Soft glaze comprises the vast range of earthen-ware and faience glazes, and includes the glazes of bone china and soft porcelain. A soft glaze is either a silicate or a boro silicate, and the bases employed include the oxides and carbonates of the following elements: Lead, zinc, potassium, sodium, calcium, barium, magnesium, and as coloring agents the salts of iron, cobalt, copper, nickel, antimony, chromium and manganese.

The range of temperature is very wide. A simple lead glaze will fuse at 900° C. and a hard glaze for white earthen-ware may need 1,350° of heat. Enamels are sometimes used over other glazes and sometimes upon the biscuit body. Their essential condition is opacity. Oxide of tin, alumina, calcium phosphate and calcium carbonate are used as opacifiers. The early wares made in Italy, Spain and Holland were of this type (see MAJOLICA). For convenience of application glazes are ground in water and held in suspension, the article to be glazed being plunged into the liquid. For this reason only insoluble substances can be used, and where it is necessary to introduce alkaline salts and soluble boric acid or borates these are rendered insoluble by being melted with insoluble and readily combined reagents, such as whiting and barium carbonate. This melt is called a "frit" and the operation of melting is known as "fritting." Hence some glazes, mainly of the second class, are called fritted glazes, and glazes which contain no frit are termed "raw" glazes. Fritted glazes are, as a rule, harder and clearer than those which contain no frit except in the case of porcelain glaze (couverte), which is made from natural substances without frit.

Glaze'brook, Richard Tetley, English scientist: b. 18 Sept. 1854. He was educated at Cambridge and was principal of University College, Liverpool, 1898-9, and has been director of the National Physical Laboratory from 1899. He has published various scientific text-books; 'Laws and Properties of Matter'; 'Clerk-Maxwell and Modern Physics'; etc.

Glazier, glā'zhėr, **Willard**, American author: b. Fowler, N. Y., 22 Aug. 1841; d. 25 April 1905. His works include: 'Capture, Prison Pen, and Escape' (1865), which was very popular; 'Three Years in the Federal Cavalry' (1870); 'Battles for the Union'; 'Heroes of Three Wars'; 'Peculiarities of American Cities'; and 'Down the Great River.'

Glazier, Lake, Minn., a body of water south of Lake Itasca, into which it empties through a swift and permanent stream about 6 feet wide; named for Capt. Willard Glazier, who claimed for it a geographical importance as the true source of the Mississippi. Lake Glazier has an area of 255 acres. It is estimated to be 1,582 feet above the Atlantic, and 3,184 miles from the Gulf of Mexico.

Glea'son, Elliott Perry, American inventor: b. Westmoreland, N. H., 27 June 1821; d. New York 26 Sept. 1901. Received a common school education; was one of the first to manufacture gas burners; and invented the regulating argand burner and other lighting devices.

Gleason, Frederick Grant, American musician: b. Middletown, Conn., 17 Dec. 1848. He was a pupil of Dudley Buck at Hartford, Conn., studied also at Leipsic, Berlin, and London, became an organist at Hartford, and in 1876 removed to Chicago, where he was active as composer, teacher, and musical critic of the *Tribune*. Among his works are songs, trios, sonatas; the cantatas, 'Praise of Harmony,' 'God Our Deliverer,' and 'The Culprit Fay'; and the operas 'Montezuma' and 'Otho Visconti.'

Glebe, glēb (Lat. "soil," "clod"), the land possessed as part of the revenue of an ecclesiastical benefice in England or Scotland, often scattered through the parish. Where there are arable lands the glebe must consist of 4 acres; where there is none the parson is entitled to 16 soums of grass next adjacent to the church — a soum of land being as much as will pasture 10 sheep or 1 cow — so that the actual extent will vary with the richness of the soil. The glebe must be taken as near the manse as possible; and where there is no manse, vicinity to the church is the criterion. In general, the glebe is the subject of much discussion in the ecclesiastical law of both countries. Although the incumbent is temporarily proprietor, he has no right of alienating the glebe.

Glede, glēd, an old British name for a bird of prey, the kite. See KITE.

Glee, in music, a vocal composition in three or more parts, generally consisting of two or three contrasted movements, the subject of which may be either gay, tender, grave or pathetic. It is distinguished from a madrigal by its want of contrapuntal harmony, and in the independence of its parts it differs from a part-song. It is essentially English in origin

and cultivation, and the period during which its vogue was greatest and its form most perfect extended from 1760 to 1830.

Gleet, glēt, chronic urethritis; an obstinate inflammation of the urethra that follows acute gonorrhœa. The disease is evidenced by the continuation of the purulent discharge, or by a morning drop, or by the presence of shreds of mucous membrane appearing in the urine. It may be due to small ulcerated patches, the presence of a stricture, or inflammation continuing in the tiny pockets and glands. The cure of the inflammation requires astringent and antiseptic injections, usually some form of silver, and under some conditions the passage of steel sounds.

Glencoe, glĕn'kō, Minn., a village and county-seat of McLeod County, on the Chicago, M. & St. P. R.R. Stevens Seminary and St. Joseph's Academy are located here. Pop. (1900) 1,780.

Glendale, Battle of, also called **the Battle of Charles City Cross-roads, the Battle of Frazier's Farm,** and **the Battle of White Oak Swamp.** The battle of Gaines' Mill was fought on 27 June 1862. That night the Fifth corps and its supports crossed to the south side of the Chickahominy and destroyed the bridges, and the withdrawal of the Army of the Potomac to James River began. The battles of Allen's Farm and Savage Station were fought on the 29th, and on the morning of the 30th the Union army was across the White Oak Swamp Creek, covering the roads leading to James River and the immense trains on their way to Malvern Hill and Harrison's Landing. Franklin, on the right, with Smith's division of his own corps, Richardson's division of Sumner's, and Naglee's brigade of Keyes' corps, was at the bridge crossing of White Oak Swamp Creek. About two miles to the left, holding the intersection of the Charles City, Darbytown, and New Market roads, thus covering the Quaker road over which the trains must pass, was Sumner, with Sedgwick's division of his own corps. Heintzelman's two divisions of Hooker and Kearny, Slocum's division of Franklin's corps, and McCall's division. Slocum, on the right of Sumner's line, was on the Charles City road, about a mile in advance of the junction with the New Market and Quaker roads; Kearny was on Slocum's left between the Charles City and New Market roads; McCall was on Kearny's left, and Hooker to the left and rear of McCall; Sedgwick was in support to McCall, but during the forenoon, two of his brigades were sent to Franklin. Porter's and Keyes' corps were at or on the way to Malvern Hill. After making these dispositions McClellan left the field.

Gen. Lee's plan contemplated that Jackson should force a passage at the bridge held by Franklin, turn his right, and reach the Union rear; Holmes to attack and turn the Union left and prevent its reaching James River, while the divisions of Longstreet, A. P. Hill, and Huger, supported by Magruder, concentrating at the cross-roads, should cut McClellan's army in two and interrupt its retreat to the river. Early on the morning of the 30th Jackson advanced through Savage Station on Franklin, who opened upon him furiously with artillery and checked him. It was a great disappointment to Lee, and Jackson's want of enterprise on this occasion has been the subject of much criticism. Holmes advanced on the Confederate right with 6,000 men and 6 batteries, toward Malvern Hill, and was attacked by Warren's brigade of 1,50c men and 36 guns; the gunboats in the river opened upon him and he fell back in disorder, and called for help. Huger led the advance down the Charles City road; in an effort to determine the Union position and to protect his own flanks, his division became scattered, and he devoted the remainder of the day to reconnoitering and an almost harmless artillery duel with Slocum. While this division of 9,000 men frittered away the day, Longstreet and A. P. Hill were maintaining a furious contest.

Longstreet and A. P. Hill moved on the Darbytown road, Longstreet in advance, who, at noon, came upon McCall's pickets on the Frazier farm. Longstreet formed line and at 3 P.M. closely supported by A. P. Hill, attacked McCall, forced back his left brigade (Seymour's) after a hard struggle, and captured several guns. Hooker, with Grover's brigade, fell upon the flank of Longstreet's right brigade (Kemper's); Sumner's artillery, covering the opening between McCall and Hooker, opened fire, and Kemper was swept back just as Branch's and Pickett's brigades were advancing to his support, which in turn were checked, but kept up a stubborn fight until nightfall, when they were joined by Pender's and Archer's brigades of Hill's division, and held the ground from which Seymour had been driven. Wilcox's brigade, which had advanced on Pickett's left, captured Randol's and Cooper's batteries after a very obstinate fight, but was forced back by a counter-attack, and Cooper's battery was retaken. Field's brigade, coming to Wilcox's support, forced back Meade's brigade and captured some guns, but Meade rallied and drove it back. Farther on the Confederate left Pryor's and Featherston's brigades attacked Kearny's left and were several times repulsed. Slocum assisted Kearny with his New Jersey brigade, and Featherston's brigade being thrown into some disorder, Gregg's South Carolina brigade was sent to that part of the field. Late in the day Caldwell's brigade of Richardson's division moved from Franklin's position and reinforced Kearny's left. Two regiments only got into line and fired a volley; the engagement was about over, and darkness came with Kearny's line intact. Only one division, McCall's, had lost any ground during the day, and it lost its commander who was taken prisoner at the close of the engagement, and 14 guns. The Union troops had resisted three separate attacks on flank and rear, and under cover of their splendid fighting, involving great losses on both sides, the immense supply trains and the reserve artillery reached Malvern Hill at 4 o'clock in the afternoon. During the night the Union army fell back to Malvern Hill. Consult: 'Official Records,' Vol. XI.; 'McClellan's Own Story'; Webb, 'The Peninsula'; Allan, 'History of the Army of Northern Virginia'; The Century Company's 'Battles and Leaders of the Civil War,' Vol. II.

E. A. CARMAN.

Glen'dive, Mont., a village and county-seat of Dawson County, on the Yellowstone River and on the Northern P. R.R. It is the centre

of a stock-raising and agricultural region and has railroad repair shops. Pop. (1900) 1,200.

Glens Falls, N. Y., village in Warren County; on the Hudson River, Glens Falls Feeder to Champlain Canal, and the Delaware & Hudson R.R. and Hudson Valley Trolley System (running from Warrensburg to Troy); about 56 miles north from Albany, 50 miles from Troy, 18 miles from Saratoga, and nine miles from Lake George. The river at this point has a descent of about 60 feet with a succession of falls and rapids. Cooper in 'The Last of the Mohicans' has celebrated the falls at this place and the famous cave which lies under the limestone formation at this point. This cave cannot be seen at high water in the spring and fall; at other times it is accessible to any tourist who wishes to visit this quasi-historical spot.

Industries.— Glens Falls is in an agricultural region; in the vicinity of the river are extensive limestone and black marble quarries which have been worked for more than half a century. At the falls, are located some of the largest, most extensive, and costly paper mills in the world, as well as various other manufactories. The chief manufactures of the city are paper, pulp, wall paper, Portland cement, lime, lumber, collars, cuffs, shirts, ladies' shirt waists, flour, laths, Joubert & White buckboards, lanterns, machinery and foundry products, ale brewing, brick (ordinary and artificial), paper boxes, cigars, confectionery, gold and silver refining, and various minor enterprises. Twelve miles above Glens Falls is situated the great Spier Falls dam across the Hudson, built by the Hudson River Water Power Company, supplying electric light and power along the Hudson and Mohawk valleys as far south as Albany and west to Utica. This power is second only to Niagara in importance in this country.

Public Works, Institutions, Buildings, Etc.— Glens Falls has several miles of paved streets, a paid fire department, police, and all modern municipal equipments. The village owns its own water works system. Glens Falls has an excellent union school system and its new high school building completed in 1906 cost over $120,000. It has also Saint Mary's and Glens Falls Academies, Crandall Free Library, Parks' Hospital, Glens Falls Hospital, Glens Falls Home for Aged Women, and the Crandall Park. There are many fine buildings including the home office building of the Glens Falls Insurance Company, the State Armory of Company K, 2d Reg., N. Y. M., the Ordway Memorial Y. M. C. A. Building, the Village Hall (costing $60,000), and the Empire Theatre Building. There are 11 churches comprising all the leading denominations. Glens Falls has three national banks and a trust company with a combined capital of $436,400 and deposits of $5,636,300.

History and Population.— Glens Falls is situated on the Great War Trail leading from Lake George to Albany. Just outside the village limits at the Half-Way Brook was located throughout the French and Indian Wars and the Revolutionary War a fortified post. A tablet was erected in 1905 by the New York State Historical Association commemorating the two massacres which occurred at that spot during this period, also the encampment there of General Riedesel with Burgoyne's forces while on their way to Saratoga. Glens Falls was settled in 1763; incorporated in 1837 and again in 1874 and 1887. In 1864 the village was practically destroyed by fire. In 1884 and also in 1902 it was visited by disastrous conflagrations entailing a loss of hundreds of thousands of dollars. Pop. (1900) 12,613; (1905) 14,650.

James A. Holden.

Glen'wood, Iowa, a city and county-seat of Mills County, 20 miles from Council Bluffs, on the Chicago, B. & Q. R.R. The State Institution for Feeble Minded Children is located here. The chief industries include fruit-growing, farming, and vegetable canning. It has a city hall, court house, and several churches. Pop. (1900) 3,040.

Gliddon, George Robbins, American archæologist: b. Devonshire, England, 1809; d. Panama, Colombia, 1857. He succeeded his father as United States consul at Alexandria, and was for a long time engaged in archæological researches in Egypt and the Levant. Later he came to the United States, and lectured in many cities on Oriental archæology, and was appointed agent for the Honduras Interoceanic Railroad Company. His principal works include: 'Appeal to the Antiquaries of Europe on the Destruction of the Monuments of Egypt' (1841); 'Discourses on Egyptian Archæology' (1841); 'Otia Ægyptica' (1849); 'Ancient Egypt'; 'Types of Mankind, or Ethnological Researches Based upon the Ancient Monuments, Paintings, Sculptures, and Crania of Races, etc.,' etc.

Glinka, glĕn'kä, **Mikhail Ivanovitch,** Russian composer: b. government of Smolensk 1 June 1803; d. Berlin 15 Feb. 1857. In 1836 his opera 'Life for the Tsar' was presented with great success at St. Petersburg. He was regarded as the founder of Russian national opera, and was appointed director of the imperial Opera and Kapellmeister to the Tsar. A second operatic work, 'Russlan and Ludmilla' (1842), was inferior. His orchestral arrangements of Russian dances became well known in foreign countries. He wrote (in Russian) 'Memoirs and Correspondence with Relatives and Friends' (1887). Consult the study by Fouqué (1880).

Glisan, glĭs'an, **Rodney,** American physician: b. Lingamore, Frederick County, Md., 29 Jan. 1827. He was graduated from the medical department of the University of Maryland (Baltimore) in 1849, was assistant surgeon, United States Army, in 1850–60, afterward practised medicine in Portland, Ore., and in 1881 was a delegate to the Seventh International Medical Congress. His writings include a 'Journal of Army Life' (1874).

Globe, a sphere, a round solid body, generated by the revolution of a semicircle about its diameter. Globe, or artificial globe, in geography and astronomy, is more particularly used of a sphere made of metal, plaster, or pasteboard, on the surface of which is drawn a map or representation of either the heavens or the earth, the former being called a terrestrial and the latter a celestial globe. The celestial globe is intended as a representation of the heavens, on which the stars are marked according to their several situations. The terrestrial globe is an artificial representation of the earth, ex-

hibiting its great divisions. The axis of the earth is an imaginary line passing through its centre, and the wire on which the artificial globe turns represents this line. The poles of the earth are the extremities of this axis. The brazen meridian is the circle in which the artificial globe turns, divided into 360 degrees. A degree of a great circle in the heavens is a space nearly equal to twice the apparent diameter of the sun, or to twice that of the moon when considerably elevated above the horizon. A degree on the equator of a terrestrial globe represents 60 geographical miles or 69.12 English miles.

Great circles, such as the equator, ecliptic, and the colures, divide the globe into two equal parts; small circles, as the tropics, polar circles, parallels of latitude, etc., divide the globe into two unequal parts. Meridians, or lines of longitude, are semicircles cutting the equator at right angles. In English maps and globes the first meridian is a great circle supposed to pass through the Royal Observatory at Greenwich. The equator, when referred to the heavens, is called the equinoctial, because when the sun appears in it the days and nights are equal all over the world. The declination of the sun, stars, and planets is counted from the equinoctial north and south. The ecliptic is a great circle in which the sun makes his apparent annual progress among the fixed stars; it is the real path of the earth around the sun. The zodiac on the celestial globe is a space which extends about 8° on either side of the ecliptic. Within this belt the motions of the planets are performed. The ecliptic and zodiac are divided into 12 equal parts called signs, each containing 30°; and the sun makes his apparent annual progress through the ecliptic at the rate of nearly a degree in a day. The colures are two great circles of the celestial sphere, one of which passes through the celestial poles and the equinoxes, and the other through the solstices and the celestial poles. The tropics are two smaller circles, each 23° 28′ from the equator, with which they are parallel; the northern is called the tropic of Cancer, the southern the tropic of Capricorn. The polar circles are two small circles parallel to the equinoctial, at the distance of 66° 32′ from it, and 23° 28′ from the poles.

Horizon when applied to the earth is either apparent or real. The sensible or visible horizon is the circle which bounds our view where the sky appears to touch the earth or sea. It extends only a few miles. The real or true horizon is an imaginary plane passing through the centre of the earth parallel to the sensible horizon. The wooden horizon circumscribing the artificial globe represents the true horizon on the earth; it is divided into several concentric circles arranged in the following order: one containing the 32 points of the compass divided into half and quarter points; another with the 12 signs of the zodiac, with the figure and character of each sign; and another having the days of the month answering to each degree of the sun's place in the ecliptic, and the 12 calendar months. The cardinal points of the ecliptic are the equinoctial and the solstitial points, which mark out the four seasons of the year.

The zenith is a point in the heavens exactly overhead and is the superior pole of our horizon. The nadir is a point in the heavens exactly under our feet, being the inferior pole of our horizon, and the zenith or superior pole of the horizon of our antipodes.

The pole of any circle is a point on the surface of the globe 90° distant from every part of the circle. Thus the poles of the world are 90° from every part of the equator; the poles of the ecliptic (on the celestial globe) are 90° from every part of the ecliptic, and 23° 28′ from the poles of the equinoctial. The equinoctial points are in the signs of Aries and Libra, where the ecliptic cuts the equinoctial. The vernal equinox is called the first point of Aries, and the autumnal the first point of Libra. When the sun is in either of these points the days and nights on every part of the globe are equal to each other. The solstitial points are in Cancer and Capricorn. When the sun enters Cancer it is the longest day to all the inhabitants north of the equator, and the shortest day to those on the south side. When the sun enters Capricorn it is the shortest day to those who live in north latitude, and the longest day to those who live in south latitude. The latitude of a place on the terrestrial globe, or its distance from the equator in degrees and minutes, or geographical miles, is reckoned on the brass meridian from the equator toward the pole. The quadrant of altitude is a thin piece of brass divided upward from 0 to 90°, downward from 0 to 18°; when used it is generally screwed to the brass meridian. The upper divisions determine the distances of places on the earth, the distances of the celestial bodies, their latitudes, etc.; and the lower divisions are applied to finding the beginning, the end, and duration of twilight. The longitude of a place on the terrestrial globe is the distance of the meridian of that place from the prime meridian, reckoned in degrees and parts of a degree, on the equator. Longitude is either east or west, according as a place is east or west of the prime meridian. No place can have more than 180°, or half the circumference of the globe. Hour circles are the same as meridians. The brass meridian and these circles always correspond.

Globe-fish, a plectognathous fish of the family *Tetraodontidæ*, examples of which are found on all the warmer coasts of the world, especially within the tropics. Ordinarily they are oval, spinose, small-finned fishes, which nibble the barnacles and crush the small crustaceans and mollusks near shore, with the rodent-like teeth which give them the name «rabbit-fishes» in the West Indies. The moment any danger threatens they suck air or water into a large bladder-like expansion of the abdomen and distend the scaleless skin until they are as round as a ball, all the spines are rigid, and they rise and float at the surface belly upward,— a difficult and disagreeable mouthful; this odd method of self-defense has given them the names «bellows-fish,» among English, and «tambor» among Spanish fishermen. Some tropical species are a foot or so in length, but those familiar as «puffers» or «swell-fish» along the coast of the eastern United States are much smaller and serviceable only as comical additions to an aquarium. The flesh of all is poor, and said to be poisonous. The two genera are Lagocephalus and Spheroides, the

latter containing the familiar northern puffers. Compare DIODON.

Globe Tavern, Battle of. On 17 Aug. 1864 Gen. Grant, then investing Petersburg, directed that Warren's Fifth corps and some cavalry be sent to destroy as much as possible of the Weldon Railroad and make such a demonstration on Lee's right as would force him to withdraw a portion of his troops from the Shenandoah valley, so that Sheridan might strike a blow at the rest of them. Warren was instructed to move at 4 o'clock on the morning of the 18th and make a lodgment upon the railroad two miles south of the Vaughan road, and destroy it as far south as possible. A brigade of cavalry under Col. Spear was attached to his command. Warren moved as directed, drove back Dearing's Confederate cavalry brigade, and took possession of the railroad at Globe Tavern, about three miles south of Petersburg. Griffin's division was formed along the road, and began its destruction. Ayres' division moved up the road a mile or more beyond Griffin, and Crawford moved up on Ayres' right. About 2 P.M. Gen. Heth, with two brigades, moved out of the Confederate works, made a sudden attack upon Ayres' left, and drove it back; Ayres rallied, and retook the lost ground. The Union loss was 544 killed and wounded, and 392 missing. On the morning of the 19th Bragg's brigade was sent to the right of Crawford to support him and establish connection by a skirmish-line with the Ninth corps, and Willcox's and White's divisions of the Ninth corps were ordered to Warren's support. The woods were so dense and the roads so intricate that Bragg failed to establish a proper line, and before it could be connected and completed it was broken. A. P. Hill with Heth's two brigades, Mahone's three brigades, Fitzhugh Lee's cavalry, and Pegram's batteries, moved to the Vaughan road intersection. At 4.30 P.M. Mahone in column of fours, broke through Bragg's skirmish-line, faced to the right, and sweeping forward dispersed Crawford's division and the right of Ayres'; at the same time Heth opened on Ayres' centre and left. Warren rallied the broken parts of his line and, advancing, regained the lost ground, taking some prisoners. Willcox's division engaged Colquitt's brigade, drove it back, and captured some prisoners; and Mahone's entire command fell back rapidly in great confusion to their entrenchments, "carrying with them the parts of Warren's command disorganized by the attack on their rear in the woods, and a large portion of the pickets." Heth made repeated attempts to drive Ayres back, but failed. Warren's casualties for the day were 382 killed and wounded, and 2,518 missing. On the 20th Warren selected a position on the railroad a mile or two in rear of his line of battle of the 19th, chiefly on open ground, and entrenched. On the morning of the 21st A. P. Hill, with his own corps, part of Hoke's division, with Lee's cavalry, attacked his position, opening with 30 guns on his front and right flank, and at 10 o'clock made an assault, which was repulsed. Later Mahone attempted an assault on Warren's left, but the artillery fire broke his ranks before they came under musketry fire, and Warren, making an advance, captured 517 officers and men and six flags. Warren's loss was 301 killed, wounded, and missing. No further attempts were made upon Warren's position, and the entrenchments were extended by the Ninth corps from the Jerusalem plank-road to unite with Warren's on the Weldon Railroad. The Union troops engaged on 21 August numbered about 20,000; the loss was 198 killed, 1,105 wounded, and 3,152 missing. The Confederates engaged numbered about 14,800; the number of their killed and wounded is estimated at 1,200. Consult: 'Official Records,' Vol. XLII.; Humphreys, 'The Virginia Campaign of 1864 and 1865'; Powell, 'The Fifth Army Corps'; Walker, 'The Second Army Corps.'

E. A. CARMAN.

Globe Theatre, the theatre in Southwark of which Shakespeare was a shareholder, and in which many of his plays were acted. The original theatre was built in 1593 on a tract of land between Maiden Lane (now New Park Street), and what was subsequently called Globe Alley; the site is now occupied by Barclay and Perkins Brewery. A patent was granted for this theatre by James I. in 1603. It was destroyed by fire in 1613 during the performance of Shakespeare's 'Henry the Eighth.' The accident was caused by the firing of the thatch roof, a cannon having been discharged during the performance, and the wadding shot from the stage pierced the roof. This was in 1613. The theatre was rebuilt the following year. In 1644 the structure was demolished to make room for dwelling houses. According to pictures and descriptions which have survived to the present day the old theatre must have been extremely dingy in the interior and uncomfortable both for the actors and spectators.

Globigerina, glŏb-ĭ-jĕ-rī'nă, one of the most common of the surface-living or pelagic Foraminifera (q.v.), a shelled protozoan of the class *Rhizopoda*. The animal is like an amœba, exceedingly simple, although throwing out a great number of long, slender thread-like pseudopods, with which it draws in and absorbs minute silicious plants, such as diatoms, etc., which serve as food. Though the animal is so simply organized, the limestone shell which it secretes is composed of several chambers, which are like their bubbles, hence the name of the commonest species, — *Globigerina bulloides*. It lives in countless numbers at the surface of the sea, floating on the top of the water, when the sea is calm, with its root-like arms or tentacles (pseudopodia) radiating from the body. The shell, which is of microscopic size, is perforated with fine openings through which the pseudopods pass out. After death the shells, when not dissolved, slowly fall or rain down to the bottom of the ocean, and so light and minute are they that it is calculated that it requires about a month for them to reach the bottom in the deeper parts of the ocean.

Globigerina Ooze.— The shells collect in such vast numbers on the floor of the ocean that a grain of the fine mud or ooze thus formed may contain nearly 50,000 of them. Chalk is formed of such foraminifers mingled with the debris of shells, corals, etc. Nummulitic limestone and greensand are mainly of foraminiferal origin. This ooze is a fine sticky mud-like sediment which covers the ocean bottom at great depths. Indeed, the ocean bottoms everywhere beyond the 100 to 500 fathom-line are free from any [illegible]

sediments. All this ooze is principally made up of the shells of this single species (*G. bulloides*) mentioned above. The more numerous these shells are at the surface, the greater is the depth at which they will accumulate at the bottom. There are only about 20 other species of these pelagic Foraminifera, yet as Murray states in his 'Report on the Scientific Results of the Voyage of H. M. S. Challenger,' so numerous are the individuals of the species that they usually make up over 90 per cent of the carbonate of lime present in the calcareous oozes of the abysses of the ocean. The remaining 10 per cent is mainly reddish clay. Great interest attaches to this subject because thick series of Tertiary and older rocks seem to have been formed out of similar oozes. Beside the globigerina oozes similar sticky deep-sea muds are formed of the shells of surface-living pteropods (q.v.), as also radiolarian oozes and diatom oozes, the latter confined to the Southern Ocean, a little to the north of the Antarctic Circle. The radiolarian ooze thus far has been detected only in the deepest abysses of the western and central Pacific. The red clay is derived by chemical changes from the globigerina ooze. See Deep-sea Exploration for information as to the method of ascertaining these facts.

Glob'ulins, a term applied to one of the forms of proteids (q.v.) of animal or vegetable origin. The animal globulins are proteids which are insoluble in water, soluble in dilute salt solution, and insoluble in saturated solutions of sodium chloride and magnesium sulphate. They are coagulated by heat, the temperature causing the coagulation varying considerably. Fibrinogen, serum globulin of blood, paramyosinogen and myosinogen, of muscle, and vitellin, found in eggs, are examples of animal globulins. The plant globulins constitute the most important and abundant natural proteids of plants.

Glo'ria in Excel'sis, the original and Latin form of 'Glory be to God on High,' the opening words of the dismissal hymn in the liturgy of the English Church as well as of the Protestant Episcopal Church in the United States. It is used in the Roman Catholic Church at all masses excepting those for the dead. These opening words are taken from the hymn sung by the angels at the Nativity. The origin of this half-inspired composition is lost in remote antiquity. It is found in the eastern Church as early as the days of Athanasius, but was used at evening service (nocturns), and not in the liturgy, or communion office. It has been attributed to Telesphorus, bishop of Rome, 150 A.D. Pope Symmachus, 500 A.D., is said to have ordered its use at the commencement of the Sunday and holy-day services. The hymn in full is as follows: "Glory be to God on high, peace on earth, to men of good will. We praise thee, we bless thee, we worship thee, we glorify thee, we give thanks to thee for thy great glory, O Lord God, heavenly King, God the Father Almighty. O Lord, the only begotten Son Jesus Christ; O Lord God, Lamb of God, Son of the Father, that takest away the sins of the world, have mercy upon us. Thou that takest away the sins of the world have mercy upon us. Thou that takest away the sins of the world, receive our prayer. Thou that sittest at the right hand of God the Father, have mercy upon us. For thou only art holy; thou only art the Lord; thou only, O Christ, with the Holy Ghost, art most high in the glory of God the Father. Amen."

Gloria Pat'ri, the first words in their original Latin of the doxology sung or said in the services of the Roman Catholic Church, the English Church, and the Protestant Episcopal Church in the United States, and other religious bodies. It is employed as a refrain at the end of psalms and canticles as well as at other parts of the service. The complete form of the doxology is as follows: "Glory be to the Father, and to the Son, and to the Holy Ghost. As it was in the beginning, is now, and ever shall be, world without end. Amen." The doxology is common at the beginning of service in the Greek Church, and was employed at nocturns in the Western or Roman Catholic Church as early as the 6th century.

Gloss (Gr. "tongue"), the explanation of verbal difficulties in a literary work, written at the passages to which they refer. The words which are commonly the subject of these explanations are those taken without modification from a foreign language, provincialisms, obsolete and technical words, or such as are used by the author in some exceptional signification. The earliest glosses, as those in Greek, Latin, and Hebrew manuscripts, were interlinear; they were afterward placed in the margin, and extended finally in some instances to a sort of running commentary on an entire book. In Roman law the word is used also of an explanation, but the explanation is not merely of a word, but deals with the intent of the law. The glosses on the Justinian code, collected by Accursius in the first half of the 13th century, were held almost as high authority as the code.

Glossitis, glŏs-sī'tĭs. Acute glossitis is an uncommon disease of the tongue due to bites, burns, and stings. It starts in the deeper structure of the tongue, causing it to swell rapidly. The affection is very painful, but is ordinarily cured, if properly treated, in five or six days. Small or large incisions may be necessary. Chronic glossitis is a condition of the tongue, due to persistent use of tobacco, alcohol, and spices, in which the surface is reddened, cracked, and furrowed.

Glot'tis, the upper end, including the opening of the windpipe, which latter constitutes a narrow aperture covered by the epiglottis during the act of holding the breath or swallowing. The glottis contributes by dilatation and contraction to the modulation of the voice. It is sometimes called the rima glottis, a term more properly limited to the opening of the windpipe. See Larynx.

Glottis, Œdema of the, a dangerous affection characterized by the effusion of serum in the tissues of the entrance and the inside of the larynx, causing an obstructive swelling. It is due to burns, scalds, and the lodgment of foreign bodies; to acute laryngitis or tonsilitis; to tuberculous and cancerous deposits; and to nephritis, measles, diphtheria, scarlet fever, and erysipelas. The symptoms which usually develop rapidly are pain, cough, loss of voice, and great difficulty of breathing. This difficulty of breathing, unless relieved, may go on to complete suffocation. Incision of the parts may

give relief, or tracheotomy or intubation may have to be performed. See NOSE AND THROAT.

Gloucester, Mass., a city and port of entry of Essex County, near the extremity of Cape Ann, and on the Boston & Maine R.R.; 32 miles northeast of Boston. It is one of the most important fishing ports and fish markets in the world, having over 500 vessels and 6,000 men engaged in the fisheries. Cod, haddock, halibut, herring, and mackerel are the principal catches. Besides extensive fisheries, the city has large manufactures of machinery, oil, fish-glue, shoes, twine, and cigars. Numerous vessels have been wrecked in the vicinity of Gloucester. A massive rock called Norman's Woe was the inspiration for Longfellow's famous poem, 'The Wreck of the Hesperus.' The city was founded in 1623, principally by settlers from Gloucester, England, from which it received its name; was incorporated as a town in 1642; and became a city in 1874. The city is governed by a mayor, elected annually, and by a bicameral council. The waterworks are operated by the city. It has the oldest Universalist church in the United States, founded in 1770. Pop. (1900) 26,121.

Gloucester City, N. J., a city in Camden County, on the Delaware River and on the Atlantic City and the West J. and Seashore R.R.'s. The manufactures include calico prints, woolen yarns, gas burners, and boats. The city was incorporated in 1868, and is governed by a mayor chosen every two years, and by a unicameral council. It has ferry connections with Philadelphia, and has electric lights and street railroads. Pop. (1900) 6,840.

Glove, an article of dress; a covering for the hand. Its use reaches back to remote antiquity. Laertes, the farmer-king, wore gloves to protect his hands from the thorns. Xenophon sneers at the Persians for wearing gloves to keep their hands warm. In their more robust days the Greeks and Romans scorned the use of gloves; but in later times they were used in Rome. The glove appears to have become a well-known article of dress in England about the 14th century, and corporations of glovers were in existence in the 15th century. In the days of Queen Elizabeth gloves were made with gauntlets upon which much rich and elaborate embroidery was worked.

Modern gloves are of two distinct classes, woven and knitted gloves, and those made of leather: and the making of these constitute entirely separate branches of manufacture. The manufacture of knitted or woven gloves is an industry allied to the hosiery trade, and the materials comprise all the ordinary fibres, the most important being silk and wool. In some cases these gloves are entirely made and finished by knitting; but in others, the pieces are separately fashioned and sewed together as in making leather gloves. The manufacture is widespread, but the headquarters of the thread and cloth glove trade are now Berlin and Saxony. The materials used for making leather gloves are principally the skin of deer, sheep, and lambs, goats and kids, the latter being the most important, though far more "kid" gloves are made of sheep than of kid leather. The skins for military and other heavy gloves — doe or buck leather — are prepared by the ordinary process of tanning, or are a fine kind of chamois leather. Those for what are called dressed kid gloves are subjected to a special method of tanning, by which, under the influence of heat, and treatment with a mixture of flour, yellow of egg, and alum, the material is rendered peculiarly soft and flexible. After the leather has been properly prepared it is cut into pieces of the required size, then folded over somewhat unequally, as the back should be larger than the front. Three cuts are then made through the doubled piece to produce the four fingers; an oblong hole is cut at the bending of the fold for the insertion of the thumb piece; the cutting of this of the exact shape and size requires considerable skill. The first and fourth fingers are completed by gussets or strips sewed only on their inner sides, while the second and third fingers require gussets on each side to complete them. Besides these, small pieces of a diamond shape are sewed in at the base of the fingers toward the palm of the hand.

A kind of vice or clamp, with minute teeth to regulate the stitches, is used in the making of hand-sewn gloves, by which method all the finest gloves are stitched. Sewing-machines are applied for the ornamental or embroidery stitching on the backs of fine gloves, and for almost the entire sewing of the cheaper and heavier gloves. The superiority of the French and the best English gloves depends chiefly on the adaptation of their shape to the structure of the hand by giving additional size where the flexure of the hand requires it.

Kid gloves are of two principal kinds, glacé and suède, according to the manner of dressing and finishing the leather used. Glacé gloves are those which are dressed, dyed, and polished on the hair or outer side of the skin, while suède gloves are carefully pared, smoothed, and dyed on the inner side of the skin for their purpose, and thus have the appearance of fine chamois. Paris and Grenoble are the chief seats of the French kid glove trade. Military gloves are made at Niort and Vendôme. Brussels and Copenhagen are also important glove-making centres. In England, Worcester is the principal seat of the glove industry; and in a specialty, the so-called English dogskin gloves made from tan skins of Cape sheep, the English manufacturers are without rivals. Rubber gloves are now made in both Europe and America and are largely used in operations demanding careful asepsis, particularly when the surgeon is forced to operate on a clean case after a septic wound. Gloves with roughened surfaces are made to facilitate the handling of instruments and ligatures. See GLOVE MANUFACTURE IN AMERICA.

Glove Manufacture, in America, dates from about the year 1760, when Sir William Johnson, chief agent of King George with the North American Indians, brought over from Scotland several families from Perthshire, which settled in the eastern part of what is now Fulton County, N. Y., calling the town Perth. Many of these settlers had been glove-makers and members of the glove guild in Scotland, and brought with them glove patterns and the proper needles and threads for glove making. The first gloves and mittens were used chiefly by the farmers and wood choppers as a protection for the hands while engaged in the rough and la-

borious work incident to their occupation. The entire output of the industry for many years was probably disposed of in the immediate vicinity. It was not until about 1809 that gloves were manufactured for more distant markets, and it is stated that Talmadge Edwards, a storekeeper of Johnstown, N. Y., was the pioneer in the manufacture of gloves in commercial quantities. Mr. Edwards took a bag of them on horseback to Albany when making a trip for the purpose of renewing his stock of merchandise. Finding a good demand for these articles, he had leather dressed in quantities, and secured farmers' girls to come to his factory to cut gloves, which were then sent out to farmers' wives to be sewed. In this manner the glove and mitten industry of the United States was established. During the incipient stages of this industry the goods produced were really mittens, and not gloves. A glove, as distinguished from a mitten, is a covering for the hand in which each finger is separately enclosed, the part above the hand varying in length according to fashion or convenience. About the year 1810 a glove manufacturer, who had been associated with Mr. Edwards, sold a part of his output by the dozen, and this is said to be the first instance in which they were sold by the quantity. The local demand continued to increase, and each year some enterprising manufacturer would venture to make an extended trip to dispose of his product. In 1825 Elisha Johnson, of Gloversville, N. Y., went to Boston with a load of gloves in a lumber wagon, making the journey in six weeks. This is said to have been the longest trip that had been made in connection with the industry up to that time, and the results were highly gratifying to those interested.

Until 1862 the manufacture of gloves in Fulton County, N. Y., although even then the chief manufacturing industry, was of comparatively small importance. The stimulating influence of a high protective tariff in 1862 showed itself in the increased business at Gloversville, Johnstown, and the adjoining village of Kingsborough, which became at once the leading sources of supply for the home market of gloves of medium grade. While the protective tariff stimulated home industry in one direction, it limited it in another. The domestic materials that could be used in glove making were confined practically to deer, lamb, and sheep skins. The peculiar qualities of the first established it firmly and independently of any tariff, but the others being inferior in quality to skins of foreign production, could not effectually exclude foreign made gloves, but were forced to share the market with them. Still, the demand for cheap and medium gloves was limited, and the American manufacturers saw their development arrested, while France, Germany, and England continued to supply all the finer grade of gloves used in this country. In 1872 the tariff on imported skins was removed amid intense opposition and doleful prediction of ruin to the home industry. A large number of skins came from all parts of the world, and the glovers turned their attention to tanning. Instantly experimenting began, and skill in tanning rapidly increased, so that the highest grade was attained, and to-day the various kinds of leather produced in Fulton County are unsurpassed in quality by that furnished in any other part of the world.

The introduction of free hides made American glove manufacturers far more prosperous than they had ever been previously. The quality of the product has steadily improved, and the variety has been increased until now American made gloves are steadily driving out the foreign gloves. The skill of American glovers is equal to that of foreign glove-makers, and in some respects — notably in the quality and style of the stitching, and in some grades, the shape — the American gloves are the best. The American glovers are more enterprising, and their styles are of a greater and better variety than foreign made gloves. Foreign expert workmen have been drawn over here from the great glove centres in Europe, so that the greatest skill has been secured here. The approximate value of the glove industry in Fulton County has reached about $10,000,000. Some of the firms do a business reaching as high as $1,000,000, but the majority, however, have small shops and do a small but profitable business.

Most of the work in Fulton County, as abroad, is done at the homes of the workers. The streets in Gloversville and Johnstown are lined with pretty and tasteful homes, in which the hum of the sewing-machine is constantly heard during the working hours of the day, but the workers are exceptionally fortunate in being able while earning good wages to enjoy all the comforts and surroundings of home, and in being practically their own masters and mistresses.

When the skins are received at the factory they are thoroughly soaked to open out the texture and prepare them for the removal of the hair. Then the skins are placed in vats of lime water, where for two or three weeks the lime works into the flesh and albuminous matter, and loosens the hair. The skins having thus been properly softened, the dirty but picturesque operation of removing the hair ensues. Before each beamer, as the workman is called, is an inclined semi-cylindrical slab of wood, covered with zinc. The skin is first spread upon this, and the broad curved beam of the knife glides across it from end to end, scraping and removing all the loosened hair, the scarf skin, and the small portion of animal matter still adhering to the skin. After unhairing, kid skins must be fermented in a drench of bran, whose purpose is to completely decompose the remaining albuminous matter, and also to remove all traces of the lime. The operation is extremely delicate.

With the preparation of kid leather, alum is the astringent curative agent. Its operation is accompanied by that of others, whose purpose is to secure elasticity, and pliability, and mainly to preserve that beautiful texture which makes kid leather superior to all others. These assistants in the process are eggs, flour, and salt. They are combined into what is called a custard, and there is certainly nothing repulsive in the idea of such a delicate agent being used. A proper quantity of the custard and a number of skins having been put together in a dash-wheel, where they are thrown about for some time, opens the pores of the skin, absorbs the custard freely, and becomes swelled by the chemical union of the custard and the skin. This having progressed satisfactorily, the skins are folded together with the fleshy side outward, and are dried by a gentle heat. They are now cured, but they are yet hard and rough. The breaking and «staking,» as they are called, are now resorted

to, to make the skins soft, pliable, and of even texture, removing the superfluous chemicals with which they have become charged, and the stiffness by manipulating the fibres. The operation of transforming the skin into leather is now finished, but age is necessary to secure perfect pliability and softness. The skins are therefore laid away to let the slow chemical operation going on within them be completed. After this has been accomplished the skins are ready for dyeing, cutting, and manufacturing.

Calf skins as well as horsehides are used in the manufacture of workingmen's gloves. They are tanned in two ways, namely, oil tan, with a preparation that makes them what is called "fire and water proof," and they are also dressed and have the same finish as the buck glove.

In the dye-rooms the skins which have already been aged are immersed in dye vats, where the delicate colors are imparted to them. The same care is not required in obtaining the ordinary range of dark colors, for these are "brushed" on, the skin being spread upon a glass slab and the dye being painted on with a brush. After they are dyed the skins are sometimes somewhat hard, and some classes have to be staked again in order to restore their pliability. The finishing touches to a kid skin are secured by rubbing the grain side over with a "stick," which imparts a gloss. The experience of Gloversville manufacturers with buck gloves has enabled them to impart a special finish to a skin the same as the suède finish, which is very popular under the title of "mocha." This is the same as suède finish, which is produced in other countries, by shaving off the grain side of the skin at an early stage of its progress. The Gloversville method is much better, however, and has more perfect results. Here the grain is removed, and the velvet finish secured by buffing the surface on an emery wheel. The surface of the leather is cut away in minute particles by this process, and the result is an exceedingly even and velvety texture, superior to that obtained by other methods.

The concluding work is as follows: A marble slab lies before the cutter on a table, and every particle of dirt or other inequality is removed before "doling." The skin is spread, flesh side up, upon the slab, and the cutter goes over it with a broad-bladed chisel or knife, shaving down inequalities and removing all the fibrous portions. The dexterity with which this is done makes the operation appear extremely simple, but any but a skilled and experienced operative would almost surely cut through the skin. The most delicate part of the glove-maker's art, in which exact judgment is required, comes in preparing the "tranks" or slips from which the separate gloves are cut. The trank must be so cut as to have just enough leather to make a glove of a certain size and pattern. The operation would be easy enough if the material were hard and stiff, and if the elasticity were uniform, but this is rarely the case.

The gussets, facings, etc., are cut from the waste leather in the thumb opening at the same operation. In olden times an outline was traced upon the leather and the pattern was cut with shears. Modern invention has produced dies and presses, which are universally used. Similar dies are used in the cutting of the thumb pieces and forchettes or strips forming the sides of the fingers.

The gloves are somewhat unsightly as they come from the sewer's hands, and must be made trim and neat. To secure these desirable results the gloves are taken to the "laying-off" room. In this are long tables with a long row of brass hands projecting at an acute angle. These are filled with steam and are too hot to touch, but by ingenious devices they are so arranged that it is impossible to burn the glove or stiffen the leather by too much heat, a common defect in ordinary methods. The operation of the "laying-off room" is finished with surprising quickness. Before each table stands an operator, who slips a glove over each form, draws it down to shape, and after a moment's exposure to the warmth, removes it, smooth, shapely, and ready for the box.

About 25 years ago a skin called "mocha" was utilized, and has been ever since, in making fine gloves, and they are finished similar to the suède finish, giving them a very velvety appearance. They are very soft and pliable, and in fact have been almost as popular as the fine kid and lamb gloves. These mocha skins are all gathered in Arabia.

In 1900 Fulton County, N. Y., produced gloves to the value of $[illegible], as against $[illegible], the total value of the output in the United States. Fulton County had 166 out of the 381 factories in the United States and 7,981 wage-earners, as against 14,180, the total number in the United States.

COMPARATIVE SUMMARY OF THE GLOVE TRADE IN THE UNITED STATES FROM 1850 TO 1900.

	1900	1890	1880	1870	1860	1850
Number of establishments	397	[illegible]	300	[illegible]	[illegible]	110
Capital	$[illegible]	$5,97[illegible]	$[illegible]	$[illegible]	$594,825	$[illegible]
Wage earners, average number	14,436	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Total wages	$[illegible]	$[illegible]	$1,655,695	$[illegible]	$[illegible]	$[illegible]
Cost of materials used	$9,554,105	$5,021,144	$4,351,469	$[illegible]	$[illegible]	$[illegible]
Value of products, including custom work and repairing	$[illegible]8,656	$10,103,821	$[illegible]	$3,998,521	$[illegible]	$708,184

The imports of gloves from all countries amounted to $[illegible] in 1900, of which we received $[illegible] from France and $[illegible]5,103 from Germany.

BENJ. LICHTENBERG,
Of J. Adler & Company, New York.

Glove or **Finger Sponge**, a poor variety of commercial sponge found about the Bermudas and in the Gulf of Mexico, which has a branching growth likened to the fingers of a hand or glove.

Glover, Elizabeth. See BENNETT, MARY E

Glover, John, American soldier: b. Salem, Mass., 1732; d. Marblehead, Mass., 1797. A shoemaker, and later a fisher at Marblehead, he was elected (1773) colonel of a militia regiment, known in the Revolution as the Fourteenth, or the "Marine" regiment. In 1775 he, with Stephen Moylan, was appointed director of the manning and equipment of vessels, in 1776 after the Continental defeat at Long Island superintended the transportation of the army to New York, and also directed the crossing of the Delaware previous to the battle of Trenton. Commissioned brigadier-general in 1777, he participated in Sullivan's Rhode Island expedition (1778), was a member of the court that tried André, and was retired in 1782. He sat in the Massachusetts convention that ratified the Constitution in 1788. A bronze statue of Glover stands in Commonwealth Avenue, Boston.

Glover, Richard, English poet: b. London 1712; d. there 25 Nov. 1785. In 1737 he published the epic poem of 'Leonidas,' which abounds in noble sentiments, considerably varied by incident and description; but wants interest, and is not sufficiently imaginative for lasting popularity. The 'Progress of Commerce' followed in 1739; one of the objects of which was to rouse a spirit of national hostility against the Spaniards and the ministry — a purpose which was much more effectually answered by his celebrated ballad of 'Hosier's Ghost.' In 1753 his tragedy of 'Boadicea' was performed with partial success. His 'Medea,' imitated from Euripides and Seneca, in 1761, obtained greater attention.

Glover, Stephen, English composer: b. London 1812; d. Bayswater, London, 7 Dec. 1870. He wrote nearly 1,500 compositions, including works for pianoforte, vocal duets, ballads, and songs, many of a sacred character, such as the 12 'Songs from the Holy Scriptures.' Among his published music are: 'The Monks of Old'; 'The Gypsy Countess'; 'What are the Wild Waves Saying?' and a setting for Longfellow's 'Excelsior.'

Glover, William Havard, English composer: b. Kilburn, London, 6 June 1819: d. New York 28 Oct. 1875. For several years he was musical critic of the London *Morning Post,* and in 1868 became conductor of Niblo's orchestra and a teacher in New York. His writings include the opera 'Ruy Blas' (Covent Garden 1861); a cantata, 'Tam o' Shanter,' first presented at the New Philharmonic in 1855 with Berlioz as conductor; and the overtures 'Manfred' and 'Comala.'

Gloversville, N. Y., city in Fulton County, on the Fonda, J. & G. R.R., 53 miles northwest of Albany. This is the most celebrated glove manufacturing centre in the world, producing over two thirds of the entire glove output of the United States. Here are the Nathan Littauer Hospital, the Parsons Free Library and other public institutions. Besides numerous large manufactories for gloves, gauntlets, and mittens, there are other factories of leather goods. It was incorporated as a village in 1851, although it was settled before the Revolution, being known as Stump City. It was chartered as a city in 1890. The municipal government under the revised charter of 1899 is administered by a mayor, who is elected by the people every two years, and a common council, elected for a like period. The members of the board of education and the water commissioners are also chosen by popular vote. The municipality owns and operates the water-works. Pop. (1900) 18,350.

Glow-worm. See FIRE-FLY.

Gloxinia, glŏk-sĭn'ĭ-a, a small genus of plants of the *Gesneraceæ,* distinguished by the somewhat bell-shaped corolla, the upper lip being shortest and two-lobed, the lower three-lobed, with the middle lobe largest, and also by the summit of the style being rounded and hollowed. The species are natives of tropical South America. They are now among the greatest ornaments of hothouses, owing to their handsome leaves and their graceful, beautifully colored flowers. The chief species is *G.* (*Ligeria*) *speciosa,* a Brazilian plant with large violet flowers, from which many fine varieties have been derived, usually associated under the specific name *G. hybrida.* Some species of *Sinningia* are also called gloxinias.

Glucic, gloo'sĭk, or **Glycic Acid,** an organic acid obtained from glucose or other compounds of a similar nature. When a solution of glucose is saturated with lime and allowed to stand for some weeks, the glucose is gradually decomposed, entering into combination with the lime to form a new substance known as glucate of calcium. By the addition of subacetate of lead, a bulky precipitate of glucate of lead is thrown down, and from this the free glucic acid may be prepared by separating the lead in the form of sulphid, by the action of sulphuretted hydrogen gas. Thus prepared, glucic acid is a colorless, amorphous mass, very soluble in water and in alcohol, and having an acid taste. The salts of glucic acid are mostly soluble in water, the sodium and barium salts being very hygroscopic. The formula of the acid is probably $C_{12}H_{22}O_{12}$.

Glucina, the oxid of glucinum (q.v.).

Glucinum, gloo-sī'nŭm, or **Beryllium,** a metallic element which occurs in the minerals beryl, chrysoberyl, phenacite, and euclase. The name "beryllium" was assigned to it on account of its occurrence in the beryl, and the name "glucinum" on account of the sweetish taste of its salts. Its chemical symbol is sometimes taken as Be, and sometimes as Gl. Glucinum is a dyad, with an atomic weight of about 9.08, and a specific gravity (when compressed) of about 1.85. It resembles steel in general appearance, and forms hard, hexagonal crystals which are unaffected by air at ordinary temperatures, and which are scarcely affected by oxygen or sulphur, even at a red heat, though when heated in chlorine the metal burns to the chlorid, $GlCl_2$. It dissolves readily in hydrochloric acid. Sulphuric acid and caustic potash or soda also dissolve it, but nitric acid, even when hot, and concentrated, acts upon it very slowly. The specific heat of metallic glucinum is about 0.400 at ordinary temperatures, but it increases rapidly as the temperature rises, and is about 0.58 at 500° F. The oxide of the metal, known as "glucina," GlO, was first ascertained to be a new earth by Vauquelin, who in 1798 obtained it from beryl, and pointed out that it differs from alumina in several important ways, notably in the fact that it does not form an alum. Metallic glucinum was first prepared by Wöhler

in 1828, by the action of metallic potassium upon fused $BeCl_2$. Glucinum forms many salts, but the metal and its compounds are of interest only to the chemist, as they are not used for any purpose in ordinary life.

Gluck, glook, **Christoph Willibald**, Ritter von, German composer: b. Weidenwang, Bavaria, 2 July 1714; d. Vienna 15 Nov. 1787. After studying six years at the Jesuit school at Komotow, where his musical talents were especially encouraged, he supported himself for a time by giving music lessons. Later he attracted the notice of Prince Lobkowitz, who enabled him to complete his musical education at Vienna. At 26 he was desired to write an opera for the court theatre at Milan and the result was his 'Artaserse,' which achieved a great success in spite of many innovations in composition introduced into the work. In 1742 he wrote: 'Demofoonte' for Milan; 'Demetrio ed Ipermnestra' for Venice; in 1743 'Artamene' for Cremona, and 'Siface' for Milan; in 1744 'Fedra' for the same theatre; and in 1745 'Allessandro nell' Indie' for Turin. His fame had now become European and he went to England to compose for the theatre in the Haymarket. On 7 Jan. 1746 that theatre was opened with 'La Caduta de' Giganti.' In London Gluck became deeply impressed with the majestic character of Handel's airs and choruses, and with the simple but natural dramatic style of Arne. Leaving London in 1746 he continued opera composition, among his later works being: 'Clemenza di Tito'; 'Le Cinese'; 'Il Trionfo di Camillo'; 'Antigone'; 'La Danza'; and 'Orfeo ed Euridice' (1762), his greatest work up to that time, and still a favorite in Germany after nearly a century and a half. It was followed by 'Alceste' (1766); and 'Paride ed Elena' (1769). In 1774 his 'Iphigénie en Aulide' was produced in Paris after a considerable amount of opposition from the musical critics of the old Italian and French school, at that time represented in Paris by Piccini. The most intense excitement prevailed; all Paris took sides, and for a long time the Gluckists and Piccinists contended with the same bitterness as did formerly the Jansenists and Jesuits, and in our own day Wagner and his opponents. The victory remained with the Gluckists. Shortly after the production of the 'Iphigénie,' the 'Orfeo' was adapted for and put on the French stage, and was followed by the 'Armide' in 1777, and by the 'Iphigenie en Tauride' in 1779, his last important work, and by many considered his greatest. It ends the series of works which directed the operatic genius of Méhul and Cherubini in France, and of Mozart, Beethoven, and Wagner in Germany. See 'Lives' by Marx (1863), Desnoiresterres (1872), Reissmann (1882).

Glu'cosan, or **Dextrosan**, $C_6H_{10}O_5$, a substance formed by heating anhydrous glucose to 340° F.; the anhydrous glucose that is required for the purpose being prepared by crystallizing ordinary glucose from its solution in 95 per cent alcohol. Glucosan is a colorless substance with a faint sweet taste. It is soluble in water and in alcohol, and is not fermentable by yeast. By the action of dilute mineral acids it is reconverted into glucose; and when heated for some time to 400° F. it turns to a brownish black color, and passes into caramel (q.v.).

Glucose, gloo'kōs (from Gr. γλυκυς sweet), a liquid substance obtained from corn, sometimes called "cereal syrup"; when in solid state, known as grape-sugar or "cereal sugar." In Europe it is chiefly made from potato starch. Men noted nature's process of changing the starch stored in the cells of plants into different forms of sugar. In the case of cane-sugar (sucrose) they knew that the plant absorbs carbonic acid from the air; other acids from the soil; and by the aid of the sun's heat a chemical process is evolved that puts into the sugar-plant sucrose or cane-sugar, and into fruits and vegetables fruit-sugar which is found more plentifully in the grape than in any other fruit.

The chemist seeks to obtain sugar from starch by a somewhat analogous process, and one similar to that carried on in the human system during the process of digestion, when starch is changed into sugar. Cane-sugar and fruit-sugar as they exist in cane and fruits are natural products, but whether nature's order of combining the various articles composing fruit-sugar as found in fruits is the same as the order of combination followed by the chemist in making sugar from starch is a puzzling and debatable question. Some claim that while the glucose of fruits and glucose as obtained by the chemist may be identical so far as their constituent elements are concerned and the proportion of each which is present, it does not follow that they are the same thing, or that their dietetic value is as great. Neither does it follow that because the chemical composition of glucose (dextrose) is almost identical with that of cane-sugar (sucrose) its food value is quite as evenly matched.

Theory and Fact on Sugar.— A committee of experts of the National Academy of Sciences, reporting to the United States government in 1884 on glucose said: "Starch-sugar is in no way inferior to cane-sugar in healthfulness"; in answer to which a dealer asked: "How is it then that I can feed a hog on cane-sugar and make him fat; but if I should feed him on glucose he would not put on an ounce of fat as long as he lives?" Here theory ran against fact, and to this day there is a conflict over the question which will not be settled until the physiologist has made elaborate studies of the effect of glucose on the human system, a task almost impracticable, because the chemical condition of each individual stomach is an unknown quantity, and because each person is a law unto himself in the use made of food.

Nature and Chemist.—In the laboratory of nature the starch or gum ($C_6H_{10}O_5$) which is formed in the plant is treated by carbonic acid taken from the air, and by other acids absorbed from the soil and carried into the plant by the sap, and through the action of light and heat is changed into cane-sugar (sucrose) $C_{12}H_{22}O_{11}$.

Art or chemistry takes starch from corn (maize), treats it with hydrochloric or other acid, which is neutralized or removed by alkali, the resultant product being glucose $C_6H_{12}O_6$, differing in its constituent elements from cane-sugar in that it contains one more equivalent of water. If to $C_{12}H_{22}O_{11}$ (cane-sugar) is added H_2O, it is equal to twice $C_6H_{12}O_6$ or glucose $C_{12}H_{24}O_{12}$. "It remains," said a prominent manufacturer of glucose, "for some one to discover means for eliminating from glucose the one equivalent of water; and, that found, chemistry

can make from starch an article the chemical formula for which is exactly like cane-sugar. And somebody will some day stumble over the method."

History of Glucose.— It was in 1792 that Lowitz announced that there was other than cane-sugar, he having obtained dextrose, a different variety, from grapes. In 1811 dextrose was obtained from starch by the action thereon of dilute sulphuric acid. By similar process Braconnot, in 1819, obtained it from linen rags, sawdust, or other vegetable fibre. During the reign of Napoleon Bonaparte starch-sugar was made to make good the deficiency which the continental blockade caused in the supply of cane-sugar. Early in the 19th century it was made from potato-starch in Germany, and during the latter half in France. From 1825 to the present time the chemists of France, Germany, and the United States have studied to improve processes, but nowhere in the world is glucose made so perfectly and at so low a cost as in the United States, where raw material is cheap, and the processes of manufacture so perfected that this country is fast meeting the European demand for glucose and causing the industry to dwindle in continental Europe. This country can manufacture glucose, send it to Europe, pay a 30 per cent tariff, and then undersell the makers of Europe, the proof of which is the statement which follows showing the exports of glucose from the United States. From 1838 the number of factories in France and Germany increased until 40 years later there were 85, and in the Austrian empire, where the industry began about 1840 or a few years earlier, over 100. In 1889 Germany had 30 glucose factories which produced 34,684,100 kilos glucose syrup; 2,748,000 kilos couleur.

The manufacture of glucose or grape-sugar from starch has been a prominent American industry for about 30 years. In March 1865 Dr. Goesling made glucose under a patent he had procured. The sample exhibited led to the formation of a stock company which purchased of Goesling, Bradley & Briggs their patent for manufacturing sugar and syrup from Indian corn. The company began the manufacture of glucose in the old sugar-refinery in Rose Street, New York. Unfortunately Dr. Goesling, the German chemist who was to superintend the manufacture of glucose, died before the first lot of glucose was marketed, and with him perished some of the secrets of manufacture. The small stock of glucose made was stored in the refinery, where later upon examination it was found in a solid condition, which alarmed the stockholders, for they knew of no use for grape-sugar, the name given to starch-sugar in its solid form. Neither knew they how to manufacture the glucose as a liquid substance. Their main dependence, Goesling was gone, and there seems to have been a lack of push, courage, and foresight on the part of the officers and stockholders of the Union Sugar Company in that they failed to secure expert chemists to work out the secrets of a process known only to Goesling. The few barrels of glucose the company owned were sold to the Tribune Association for a nominal sum, for use in the printing-rooms, after which the company came to grief, having paid $600,000 for the patents subject to a right to manufacture that belonged to a man named Fox. In 1877 the receiver of the Union Sugar Company sold for $2.50 the patents it controlled. A. W. Fox & Company did better. They improved the process and, while at first they used 200 to 300 bushels of corn per day, they gradually increased the quantity until thousands of bushels were daily required. In 1874 the Buffalo Grape-Sugar Company was organized; it grew into a vast concern, and might be said to be the parent of the present industry.

In 1884 there were 29 factories engaged in the manufacture of sugar or syrup from corn and having a combined capacity for absorbing 40,000 bushels of corn per day. At present there are five factories which in 1902 used an average of 175,000 bushels of corn every day. Four of the five companies are constituent properties of the Corn Products Company. The other, the New York Glucose Company, Shadyside, N. J., is of recent construction and is the only independent establishment in the country. The authorized capital of the Corn Products Company is $80,000,000. The process of manufacture has been greatly improved, so much so that, while in 1882 26 to 30 pounds of glucose was obtained from one bushel of corn, 40 pounds is now obtained. Glucose forms one of the leading exports, besides being very extensively used by brewers, candy-makers, preservers, honey-dealers, and manufacturers of vinegar.

Manufacture, Composition, and Commercial Standard.— The manufacture requires 80 hours, and includes 18 processes of manipulating the corn and starch obtained therefrom: (1) steeping; (2) grinding; (3) separation of the starch; (4) cleaning the starch; (5) collecting the starch; (6) washing the starch; (7) conversion by the action of hydrochloric acid; (8) neutralization; (9) bag-filtration; (10) bleaching with acid; (11) bone-black filtration; (12) concentration; (13) second bag-filtration; (14) acid treatment; (15) second bone-black filtration; (16) final concentration; (17) final filtration; (18) final treatment. After the corn is steeped it is ground in water, and the wet starch separated and converted in copper converters by the action of hydrochloric acid, which is later neutralized by chalk or other alkali; subjected to filtration, then concentrated in a vacuum-pan until it tests 41° Baumé or higher, the difference being in the amount of water eliminated; the product, glucose, a liquid substance, or grape-sugar if the process of conversion is carried farther.

The following observations are taken from a paper on 'The Determination of Glucose,' by Edward Gudeman (1902), Bulletin No. 73, Bureau of Chemistry, United States Department of Agriculture. Glucose is a thick amber-colored syrup 41° to 45° Baumé, containing 13 to 22.5 per cent of water. Grape-sugar is a solid 41° to 45° Baumé, containing 11 to 21.0 per cent of water. The old standard Baumé scale is still used in this industry, and the determinations are made at 140° F., results reported at 100° F., a correction of one degree being made for every 40° F. The standard accepted by the manufacturers and the trade is specific gravity 1.41152 — 42° Baumé. The conversion of starch with acids gives the commercial products known as dextrin, glucose, grape-sugar, and anhydrous grape-sugar (dextrose). Starch and its conversion products do not contain over 1 per cent impurities.

"If the conversion of starch with acid is carried to a point where a dilute iodine solution will just give a distinct color-reaction, we have glucose; continued to where 95 per cent alcohol gives a faint cloud, hardly a precipitate, we have grape-sugar containing about 85 per cent reducing-substance. For still higher converted sugars a time-factor must be introduced. Carried beyond a given point, a back conversion takes place, with strong decomposition and loss of purity.

"The ratio of the reducing-substance to non-reducing substance depends on the accuracy in stopping the conversion, for neutralization, at the exact point decided upon. This ratio determines whether the product is glucose or grape-sugar, and no sharp dividing line exists. The rotating powers of glucose and grape-sugar depend absolutely on this ratio. Actually no two batches of commercial glucose or grape-sugar are identical; for all practical purposes they are alike, as a few points either way from the standard decided upon will make no difference in the appearance, taste, or working qualities of these products."

Non-crystallization.— Glucose does not crystallize, as does cane-sugar (sucrose). A chemical process was devised by Dr. Arno Behr for the crystallization of glucose, but it is regarded as impracticable by reason of being too expensive. Dr. Behr added to the liquid glucose a very small quantity of crystallized anhydrous dextrose. The mixture is filled into molds, and in 72 hours will be a solid mass of crystals of anhydrous dextrose. The blocks are next placed in a centrifugal machine to throw out the still liquid syrup, and the anhydrous dextrose remains as a crystalline mass.

Varieties of Use.— Because glucose does not crystallize it is used extensively in the preserving industry. Fruit put up in a syrup wholly or partially made of glucose has a more plump and natural appearance than if preserved in sugar. Comb-honey, when put into glass jars, is surrounded by glucose which does not change in color or character, and therefore the honey always remains pleasing to the eye. It is very largely used for mixing with cane-sugar molasses; in the manufacture of table-syrup; as a substitute for malt in brewing; and very freely in the manufacture of candy. It is said to have from one half to two thirds the sweetening power of cane-sugar. The extent to which glucose is used in the making of jams, jellies, marmalades, preserves, and canned fruit, together with tables showing the composition of commercial glucose and the composition of the ash of glucose, has recently (1902) been stated in Bulletin No. 66, Bureau of Chemistry, United States Department of Agriculture; also with extensive tables showing the composition of the jams and other preserves in comparison with such as contained no glucose. This bulletin was prepared under the direction of W. D. Bigelow, chief of food laboratory.

Glucose is very largely used in the manufacture of confectionery. Some candies are nearly all glucose, particularly such as are sold for a penny. In the high-grade confections the finest grade is used, not as a substitute for sugar, but in the place of cream of tartar to "kill" or soften the grain of sugar, for which purpose only a small quantity is used. It is also used as a substitute for malt in the brewing of ale or beer, it being claimed that a lighter beer results than when pure malt is used, and that it is more palatable. It is assumed that converted glucose is the same as the glucose which results from the action of diastase in changing the starch in malt into maltose sugar. By using glucose direct, trouble and expense are saved to the brewer, as he is not compelled to use materials which are, in the process of the brew, converted into glucose or grape-sugar. It is claimed that 100 pounds of glucose or grape-sugar is equal to 123 pounds of barley-malt, and is much cheaper. Various publications of the United States Department of Agriculture and the reports of Congressional committees contain a great deal of information on the use of glucose in brewing.

The Wholesomeness of Glucose.— This is really the most important question connected with glucose, and one that is still unsettled. It is a problem for the physiologist rather than the chemist. Owing to many improvements made in the last 20 years, the conclusion rendered by the government's experts in 1884 could be made much more emphatic in 1903. It was as follows: "The starch-sugar thus made and sent into commerce is of exceptional purity and uniformity of composition, and contains no injurious substance. Though at best having only about two thirds the sweetening power of cane-sugar, yet starch-sugar is in no way inferior to cane-sugar in healthfulness, there being no evidence before the committee that maize starch-sugar, either in its normal condition or fermented, has any deleterious effect upon the system, even when taken in large quantities."

On the other hand, E. H. Bartley, M.D., professor of chemistry and toxicology in the Long Island College Hospital, in a paper read before the American Chemical Society, 12 Jan. 1895, claims that glucose promotes gastric disturbances. "The principal forms," he says, "in which sugar is presented to the stomach by nature's foods are either milk-sugar or cane-sugar. These sugars are very different in properties from dextrose, and require digestion before they can be used in the body. They are not capable of assimilation as such, and must be converted into a glucose before they can be used, and this is only done in the intestine. From this it would seem that it was not intended that dextrose and levulose should be taken in any considerable amount in our food. They are not natural, but artificial foods. . . . It is not a rare thing to find persons who can eat rock-candy or maple-sugar with no unpleasant after effects, but the same amount of ordinary glucose-candy will cause distress or produce what is known as 'bilious vomiting.'" Dr. Bartley adds that he has "known several cases of death produced in this way, and in every case it was with candy containing glucose." On 4 Sept. 1903 Dr. Bartley confirmed the statement quoted above, and expressed the opinion that "glucose is not a wholesome food," and that "much damage is done by a too free use of it. The fact is that diabetics lose flesh rapidly. I can therefore believe the statement that while we know that cane-sugar, maltose, and milk-sugar will fatten, glucose will not."

Other authorities give an opinion similar to that of Dr. Bartley; but doctors disagree, and some of them certify that glucose is pre-eminently a fat-forming, heat-producing food; not only not injurious, but an essential article of food, with-

out which in some form man cannot enjoy life. Such statements are based on the theory that chemistry and nature work by identical methods and produce identical substances. Says Dr. Cyrus Edson of New York: "Chemistry has shown man how to imitate exactly the product of nature. The honey of the flower and numerous other products of nature's laboratory can not only be imitated by man, but exactly reproduced by him through the agency of chemistry."

Dr. H. W. Wiley, chief chemist of the United States Department of Agriculture, testified before a committee of the United States Senate as follows: "I have had occasion to make careful examinations of almost every variety of food that has ever been exposed upon our markets for sale. In my opinion glucose is not deleterious to health. It is wholesome, somewhat sweet, readily digested. I have always found, from the time I first began to investigate food products, that the series of foods known as glucose or grape-sugar, when properly made, are valuable food material and not injurious."

The settlement of the vexed question of the wholesomeness of glucose, and its dietetic value as compared with cane-sugar, may be left to the physiologists. It is sufficient to add here that at least $50,000,000 is at present employed in its manufacture; that the industry is a great boon to the farmer, and adds materially to the revenue of the corn-producer; that official figures indicate that 1,200,000,000 pounds of cereal sugar and cereal syrup are annually consumed in the United States, while the foreign demand for them is constantly growing; that the exports of glucose or grape-sugar more than doubled from 1893 to 1901, rising from 101,546,814 pounds to 204,209,974 pounds; that in seven months of 1903 they reached 91,267,920 pounds, valued at $1,727,969, or 1.9 cents per pound; and that during 10 years, 1893–1903, the total exports were 1,708,201,551 pounds, valued at $28,139,768, or 1.06 cents per pound.

F. N. Barrett,
Of the 'American Grocer,' New York.

Glucosides, gloo'kō-sīdz, a large class of substances occurring in plants, which are distinguished by decomposing under the influence of ferments, acids, and alkalies into sugar and usually one other substance the nature of which differs with different plants. The composition of the glucosides varies, sometimes nitrogen is present, but in general the compound consists only of carbon, hydrogen, and oxygen. Their constitution is practically unknown; they have never been formed synthetically; only a few seem to be of the nature of compound ethers. When decomposed by the agents above mentioned they assimilate water, and usually yield glucose or dextrose, but some glucosides furnish other kinds of sugar. Of these naturally occurring compounds may be mentioned æsculin, colocynthin, which yields sugar and colocynthein; convallarin; convolvulin; crocin; daphnin; datiscin; digitalin; euxanthic acid; fraxin; gallotannic acid or tannin; glycyrrhizin; jalappin; phloridzin; populin; quercitrin; salicin; scammony; and xanthorhamnin. The following contain nitrogen; amygdalin; chitin; gelatin or isinglass, which when boiled for a long time with dilute sulphuric acid decomposes and yields a sugar; solanin; and myronic acid, in which sulphur is also present. The majority of these bodies are described under their respective heads. Amygdalin (q.v.) was the first known glucoside.

Glue, an impure gelatine, used as an adhesive, and commonly prepared from the clippings of hides, hoofs, horns, and sinews. These are steeped in lime-water, to remove the hair and blood, and then drained and dried in a current of air, that the lime may absorb carbonic acid, and thus prevent the injurious effects of the alkali upon the gelatine. The dippings are then boiled in water until the solution is found to gelatinize firmly on cooling. The impurities are allowed to settle, and the residuum to gelatinize in shallow wooden boxes; it is then cut into slices and dried upon nets. Good glue is semi-transparent, and free from spots and clouds. Marine glue, a composition used for cementing materials that are exposed to moisture, is made by dissolving 1 part of india-rubber in 12 parts of mineral naphtha, and adding 20 parts of powdered shellac; it resists wet, and cements glass and metals as well as wood. White fish-glue, or diamond cement, is made of isinglass dissolved in alcohol.

The glue industry in the United States was founded by Peter Cooper in 1827, when he established a factory in Brooklyn. About the same time a factory in Philadelphia was started by Charles Baeder and William Adamson. At present glue factories are centralizing near the great slaughter-houses of the Middle West, the sources of raw supplies, and the larger packing concerns, notably the Armours and the Swifts in Chicago and the Cudahy Company in Omaha, have their own glue plants. (See Packing Industry.) The factories still in the East are largely supplied with imported hides. The export trade is steadily growing and has passed the $500,000 mark per annum. France alone surpasses America in the quality of its finer glues, and these are imported for use in making straw hats. The finest glues made in the United States are prepared from sinews, and it is likely that continual experiment upon them will result in a product equal to the best imported from France. The following statistics show the growth of the industry since 1880:

GLUE FACTORIES IN THE UNITED STATES, 1880-1900.

	1880	1890	1900
Number of establishments	82	62	61
Capital	$3,916,750	$4,859,266	$6,144,407
Wage earners	1,801	1,697	1,618
Wages	$600,018	$676,089	$685,096
Cost of materials	$2,786,342	$2,510,927	$3,767,023
Value of products	$4,324,072	$4,270,460	$5,389,006

Glut-herring, or **Blueback**, a herring (*Pomolobus æstivalis*), abundant in the Southern States, and very similar to the alewife (q.v.), but it is more elongated, is darker on the back and has a black peritoneum and comparatively small eyes. The quality of its flesh is poor.

Gluten (Lat., glue), that constituent element in the vegetable kingdom which makes muscle and builds tissue. It is a combination of two substances, glutenin and gliadin, the latter forming about two thirds, the former one third, as found in wheat. It is a variable constituent of cereals that is now separated from the grain and used for human food and animal feeds. It has been designated as the spinal column in all vegetable life, and is a nitrogenous substance, belonging to the albuminoids, such as the white of egg, the lean of meat, etc. The "hard" wheats are richer in gluten than the "soft" varieties, and the gluten obtained from wheat is of higher dietetic value than the gluten of corn or rye, the latter being soft and of peculiar odor.

To obtain gluten from wheat, the grain is reduced to dough, and the starch removed by mechanical processes, the resultant product being a grayish, tough, elastic, sticky substance which, when produced in its purity and rightly proportioned in its gliadin-glutenin content, is capable of being drawn out into long bands or shreds.

In its highest refinement, gluten exhibits a fine molecular structure, delicate and sensitive to atmospheric conditions, and requires, after separation, immediate handling in its preparation for food.

About 16 pounds of gluten is obtained from 200 pounds of wheat-flour. On account of its high content of nitrogen, gluten soon deliquesces, sours and spoils after the separation from the starch, and demands an immediate treatment if desired for food purposes.

There is great variation in the character of the so-called gluten foods on the market, some of which are almost worthless and a fraud upon the public. Analyses made by the United States Department of Agriculture, by the Maine agricultural experiment station, and other agricultural stations, the results of which may be found in various bulletins issued by these organizations, show that many of the so-called glutens generally found on the market are scarcely better than ordinary white flour or bread.

The glutinous and other residues from the manufacture of starch and glucose are dried and made into cattle-feed, having a nutritive value about equal to brewer's grains. The glucose and starch makers assume that maize or corn consists of starch, gluten, germ, and bran, all but the starch being by-products, which are separated by injurious mechanical processes. The wet or free germs of the corn are dried, ground to meal, the oil extracted by hydraulic pressure, leaving oil-cake, a cattle-feed extensively used. The wet starch is run over vibratory sieves and over long wooden tables, the starch and gluten forming the mixture which passes through the sieves; the starch being deposited by gravity, the gluten passes off at the ends of the tables, forming wet gluten, which, when pressed and dried, constitutes the gluten-meal of commerce. About 5½ pounds is obtained from one bushel of corn.

The composition of gluten-meal is, protein 38 per cent, fat 3 per cent, and starch 40 per cent. This is one of the richest and best food products on the market. The nutritive value is very high, and the factor of digestibility ranges from 92 to 96 per cent. The gluten-meal is treated for the recovery of its starch, and gives two new products, a concentrated foodstuff, characterized by the large amount of proteids (60-70 per cent) it contains, and a maltose syrup. This foodstuff is suitable for animal consumption, and also for raising the percentage of proteids in feeds that have a small amount of these substances. When the wet bran and the wet gluten are mixed in the proportions as obtained from the original corn and the mixture dried, the resulting feed is known as gluten. This is the most common food product in the starch and glucose industry, and represents about 80 per cent of the food output. Its feeding value is very high, and its digestibility above 90 per cent. Its composition is about 28 per cent protein and 3 per cent fat.

Corn oil cake and gluten-meal are exported extensively. The bran and gluten feed is used almost exclusively in the United States. The production per bushel of corn is about 12½ pounds of feed.

The New York agricultural experiment station Bulletin No. 198, November 1901, gives the result of analyses of feeding stuffs. The gluten-feed was of sorts ranging in price from $19 to $22 per ton. They show a protein content of from 14.8 per cent to 28.7 per cent; fat, 2.4 per cent to 5.6 per cent; some contained as high as 11.7 per cent crude fibre. Gluten-feed, made in Buffalo, from 24.9 per cent to 27.4 per cent of protein, sold under guarantee of 28 per cent; fat, 2.7 per cent to 4.2 per cent, sold under guarantee 3.3 per cent. Prices, $20 to $21 per ton. Gluten-meal, made in Chicago, 36.8 per cent to 39.1 per cent protein; 3.0 to 4.8 per cent fat; price $24 to $25 per ton.

The waste product in the manufacture of starch or sugar is relatively much richer in oil and protein than is corn. Most factories are removing part of the corn-oil from the waste, so that nearly all the gluten-meals carry much less oil than they did a few years ago. Gluten-feeds differ from gluten-meals in that they contain a good deal of the corn-bran, and hence less of protein and digestible carbohydrates, and more of the indigestible woody fibre. The relation of gluten to bread making is set forth in detail in Bulletin No. 67, United States Department of Agriculture. The food value of gum-gluten has been outlined by Prof. Nelson Clark Parshall in a pamphlet published by the Pure Gluten Food Company, New York.

F. N. Barrett,
Of the 'American Grocer,' New York.

Glut'ton (*Gulo*), a genus of carnivorous quadrupeds related to the sables and martens, but larger and distinguished by the moderately elongated head and the long, rather low body. Intermediate between the plantigrades and digitigrades, it has rounded, very short ears, and a simple fold below the tail, which distinguishes it from the badger, which is pouched and which the glutton otherwise resembles. The commonest species in America is the *Gulo borealis* or

luscus, better known as the wolverine; it is about 28 inches from the tip of the nose to the root of the tail, which is about 8 inches long, if the hair at the extremity, 3 or 4 inches long, be included. The body is covered with thick, long hair. In summer its coloring is: face blackish as high as the eyebrows, and between these and the ears whitish or brownish; ears covered with coarse hairs; the lower jaw and the inside of the fore legs spotted with white; the back, thighs, and belly, brown or brownish black; sides, chestnut color. Its fur is of value and is used in northern Asia, where the wolverine is a native, for making and ornamenting robes. The animal, however, does not breed in sufficient numbers to furnish much fur to the traders. It is very voracious — although more so in fable and legend than in actual fact — at the same time slow and heavy in its motions, but remarkably acute in sight and hearing. It is of powerful frame, a match for any animal of its own size, and makes a strong resistance when attacked. It is one of the most destructive quadrupeds found in the northern part of America, killing numbers of young foxes and other animals; it is also a great enemy to beavers, watching for them as they come out into the open, or even breaking into their habitations.

Glycerin, glĭs'ē-rĭn, or **Glycerol.** In 1783 Scheele showed that by acting upon olive oil by oxid of lead a substance may be obtained which has a sweetish taste; and in the following year he showed that the same substance may be had by acting in a similar manner upon other oils and fats, such as butter. He also observed that the substance in question may be obtained in the form of a syrupy fluid; that although it has a sweetish taste like sugar, it cannot be fermented; and that although it gives oxalic acid by oxidation, it differs from sugar in many respects. He failed, however, to ascertain its true relation to the oils which furnish it, and to the lead plaster (or "lead soap") which accompanies its formation. The true explanation of the reactions was given some 30 years later by Chevreul, as a result of his famous researches upon the animal fats, which were begun about 1811, and were concluded about 1823. In the course of these researches Chevreul showed that an animal fat consists, in general, of a mixture of several definite chemical substances, each of which is itself a fat, and each of which consists of Scheele's sweetish substance (which is now called "glycerin"), combined with an organic acid. When the fat is treated with an alkali, or with lime or oxid of lead, the organic acid that is present combines with the alkali, or the lime, or the lead, to produce a new substance called a "soap," the organic base (glycerin) which was previously combined with the acid being thereby set free. Since the time of Scheele and Chevreul much attention has been paid to glycerin and its compounds, and it is now universally agreed that glycerin is a triatomic alcohol (see ALCOHOL), having the formula $C_3H_5(OH)_3$; and that it forms an acid and an oxid, and various substitution compounds and esters, of which latter class the fats (q.v.) are the most important members, and are distinguished by the name of "glycerides."

Glycerin sometimes occurs in nature in the uncombined form, notably as a constituent of palm-oil, and it is also a product of fermentation; but it is obtained on the large scale only by the decomposition of the fats. In soap making the fat is decomposed by heating with an alkali, the soap which is formed by the combination of the alkali with the organic acid of the fat remaining in solution until it is precipitated by the addition of common salt. The fluid that remains after the soap has been so precipitated contains the liberated glycerin, which can be separated by distilling in a partially exhausted boiler, the glycerin passing over with the water vapor, from which it may be subsequently separated by re-evaporation.

Glycerin is obtained in large quantities as a by-product in the manufacture of so-called "stearin" candles. In this case the fat is not saponified by an alkali, but beef fat, or some other fat that is rich in stearin, is acted upon by superheated steam, by which the stearin, or stearate of glycerin, is resolved into free stearic acid and free glycerin. Fat undergoes a similar transformation when treated with a mineral acid; but this method of producing glycerin has the disadvantage that the mineral acid is likely to combine to a certain extent, either with the glycerin, or with the liberated fatty acid, necessitating a subsequent treatment for its removal.

Pure glycerin is a colorless, odorless, syrupy liquid, with a pronounced sweet taste, and a specific gravity of about 1.27. It is insoluble in ether, but it mixes in all proportions with water and with alcohol. It has a considerable affinity for water, and absorbs moisture from the air quite readily. It boils at about 600° F., but with partial decomposition. Under reduced pressures it boils at lower temperatures. At a pressure of 12.5 millimetres of mercury, for example, it boils at 356° F., and may be distilled without change. By freezing, absolutely pure glycerin may be obtained in the form of deliquescent crystals, belonging to the trimetric system, and melting at about 68° F. Glycerin burns with an almost colorless flame, and dissolves many organic bodies that are insoluble in water. It also dissolves iodine, and many of the metallic oxids.

The solvent properties of glycerin render it valuable in pharmacy. It is also greatly used in the manufacture of nitroglycerin (q.v.), as a constituent of various toilet soaps, creams, and washes, as a preservative medium, and for use in gas meters and other mechanical appliances in which a liquid is needed which will not readily freeze nor evaporate.

Glycin, glī sĭn. See GLYCOCOLL.

Glycocholic (glī-kō-kŏl'ĭk) **Acid,** an organic acid, whose sodium salt is one of the main constituents of the bile of certain of the vertebrates. It may be most conveniently prepared by the following method: A drop of hydrochloric acid is added to fresh bile, and the mixture is shaken and filtered. The filtrate is allowed to stand after being shaken with hydrochloric acid and ether, until the glycocholic acid separates in the form of a bulky mass of needle-like crystals. These are collected upon a filter, washed with water containing hydrochloric acid and ether, and finally purified by recrystallization. Glycocholic acid is slightly sweet and bitter in its aqueous solution. It is readily soluble in alcohol, but dissolves sparingly in water, ether, and other solvents. It forms numerous salts, known as glycocholates, which are all sol-

uble in alcohol. Those of the alkalis are also soluble in water, and yield lathers, like soap. Glycocholic acid has the formula $C_{26}H_{43}NO_6$, and when heated with potash it is resolved into cholic acid ($C_{24}H_{40}O_5$) and glycocoll ($C_2H_5NO_2$), apparently according to the equation $C_{26}H_{43}NO_6 + H_2O = C_{24}H_{40}O_5 + C_2H_5NO_2$.

Glycocoll, glī'kō-kŏl, **Glycin, Glycocin, Amido-Acetic Acid**, or **Gelatin Sugar**, a singular chemical substance obtained by heating glycocholic acid (q.v.) with an alkali, or by the long-continued boiling of gelatin, glue, or gelatinous tissues, with sulphuric acid, or with potash or baryta. When perfectly pure it crystallizes in tabular, monoclinic crystals; but slight quantities of certain impurities induce remarkable changes in its crystalline form. It is insoluble in alcohol and in ether, but is sparingly soluble in water, its solution having a sweet taste. According to its mode of formation from glue, glycocoll is a sugar, the glue acting the part of a glucoside; but it resembles an acid (although it is neutral to litmus paper) inasmuch as it combines with metallic oxids to form salts. It does not form salts with the metals of the alkalis, and probably not with those of the alkaline earths. In combining with acids, glycocoll acts as a base, forming definite salts such as the nitrate, acetate, oxalate, sulphate, and hydrochlorid. In these compounds the glycocoll has strongly basic properties, and, indeed, it is usually described as a base. The chemical formula of glycocoll is $C_2H_5NO_2$; or $CH_2(NH_2).COOH$.

Glycogen, glī'kō-jĕn ($C_6H_{10}O_5$), animal starch, a substance found in the livers of most animals, and to a very large extent in the muscles and other parts of fœtal animals. It is extracted from the liver of a newly killed animal by cutting the liver in pieces, plunging it into boiling water, triturating it to a fine paste, and extracting with water. The filtered fluid is mixed with moderately strong alcohol, which throws down a flocky precipitate. This is purified from coloring and nitrogenous matter, and at last the glycogen is obtained as an amorphous white powder, without taste or smell. It dissolves in water, but the solution is not absolutely clear; it is insoluble in alcohol. By boiling with acids, or by the action of ferments, glycogen is readily converted into sugar. By nitric acid it yields oxalic acid. The chief interest attaches to the physiological function of this substance, and the very discordant views taken with regard to it by different writers. Thus it is said to be the substance in the liver mainly concerned in the conversion of starch into sugar. Other physiologists affirm that no such transformation takes place, there being no proof of the increase of sugar after the action of the liver; so that at the present time its exact functions are unknown. It has been suggested that the sugars that are taken into the system with the food are stored up in the liver in the form of glycogen, to be drawn upon subsequently, according to the needs of the system.

Glycol, or **Ethylene Alcohol**, the most important of the dihydric alcohols (see ALCOHOL and FATTY COMPOUNDS) may be regarded as derived from the hydrocarbon ethane, C_2H_6, by the substitution of two molecules of hydroxyl (OH) for two molecules of hydrogen. It therefore has the formula $C_2H_4(OH)_2$. Glycol may be prepared by acting upon ethylene dibromide, $C_2H_4Br_2$, by potassium carbonate, K_2CO_3. The reaction is $C_2H_4Br_2 + K_2CO_3 + H_2O = C_2H_4(OH)_2 + 2KBr + CO_2$. Glycol is a colorless, odorless liquid, having a specific gravity of about 1.12, and a sweetish taste. It boils at about 388° F., and solidifies at 11° F. It mixes in all proportions with water and alcohol, and is used to some extent as a solvent. A great many compounds have been derived from glycol, but they are not of general interest. The word "glycol" is also used as a generic name for all the dihydric alcohols.

Glycollic (glī-kŏl'ĭk) **Acid**, or **Oxyacetic Acid**, an organic acid having the formula $HOCH_2.COOH$, whose potassium salt (that is, potassium glycollate) exists in the grease obtained from sheep's wool, and in the juice of unripe grapes. It may be prepared by heating a mixture of glycerin, water, calcium hydrate, and precipitated silver oxid for four hours, after which the fluid is filtered, saturated with carbon dioxid, boiled, filtered again, and finally evaporated until calcium glycollate crystallizes out. The calcium glycollate is next decomposed by oxalic acid, and the filtered solution is neutralized with carbonate of lead. Upon evaporation, well-developed crystals of lead glycollate separate out; and a solution of these, when treated with the proper amount of sulphuric acid, yields free glycollic acid. By evaporation in a vacuum over concentrated sulphuric acid, and subsequent recrystallization from solution in anhydrous ether, the acid may be obtained in a very pure form. It is freely soluble in water, in alcohol, and in ether. Concentrated nitric acid oxidizes it to oxalic acid; and when distilled with excess of quicklime it decomposes with liberation of methane and hydrogen. Glycollic acid forms an extensive series of salts called glycollates, and it also yields numerous esters and other organic derivatives.

Gly'cosides, a class of vegetable principles which under the influences of heat, enzymes, or chemical action split into some form of sugar and some other body. Those glycosides which split into sugar and some other body are known as glucosides. When the sugar is rhamnose they are known as rhamnosides; if arabinose, they are known as arabinosides, etc. There are a great many glycosides in nature, and within recent years a large number have been made artificially. The chemical composition of the artificial glycosides is well understood, since they are the result of synthesis, but the make-up of the natural glycosides is not well understood. Glycosides play a very important role in nature. By reason of their bitterness and of their often being poisonous, they preserve seeds from destruction by animals, man included, until they shall have ripened, and then on germination plant enzymes or ferments acting on the glycosides set free a certain amount of sugar, which is of much service to the young developing plant. An excellent illustration of their protective qualities is seen in persimmons, which, when green, are so puckery by reason of the glycoside tannic acid that they are left severely alone. When ripe, however, the tannic acid is converted largely into sugar, and the fruit, then eaten and carried about by animals, can distribute its seed. In wild-cherry bark and in bitter almonds there is a glycoside amygdalin which is con-

verted into sugar and hydrocyanic acid. In mustard the glycoside sinagrin acted upon by the plant ferment also found in the seed develops into sugar and the volatile oil of mustard plaster. Many fungi are capable of accompanied by its special ferment. Many glycosides are affected by heat. Some are split by cooking in water, but a boiling temperature is apt to destroy the action in many. Thus it is necessary to use cold water if one desires to obtain the volatile oil of mustard in making a mustard plaster. Many fungi are capable of breaking down glycosides, which fact is of a great deal of practical importance in medicine, for many active remedies which contain glycosides, if kept too long on the druggist's shelf, develop molds within them. These destroy the active principle of the drug and thus render it useless. In medicine the most important glycoside containing drugs belongs to what is known as the "digitalis group." Thus digitalis contains four or five, strophanthus two, apocynum two, and squills the same number. These bodies are all heart tonics in small doses and heart poisons in larger amounts. Consult Van Rijn, 'Die Glycoside' (1900).

Glycosuria, the presence of glucose in the urine. See DIABETES MELLITUS.

Glycyrrhizin, glĭs-ĭ-rī'zĭn, or **Liquorice Sugar,** a peculiar organic substance which occurs in liquorice root (*Radix Glycyrrhizæ*), together with starch, malic acid, and various other matters. It may be prepared by extracting the dried and pulverized liquorice root with boiling water containing a small quantity of milk of lime, and precipitating the concentrated extract with cold acetic acid. The gelatinous precipitate is purified by dissolving it in 50 per cent alcohol, filtering through charcoal, and finally evaporating at 212° F. When dry, glycyrrhizin is an amorphous solid, which swells up in cold water but does not dissolve. It is only slightly soluble in alcohol or ether, but dissolves in hot water, and also in boiling glacial acetic acid. It reduces Fehling's solution when heated, and has been regarded as a glucoside; but although boiling with dilute acids decomposes it, it does not appear that any glucose or other sugar is formed, the chief products of the decomposition being parasaccharic acid and a brownish resin called glycyrrhetin. Glycyrrhizin is now more commonly regarded as a tribasic organic acid, and the name "glycyrrhizic acid" has been assigned to it. It has the probable formula $C_{44}H_{63}NO_{18}$, and forms numerous salts, which mostly have a sweet taste.

Glyoxal'ic Acid. See GLYOXYLIC ACID.

Glyox'aline, a substance having the chemical formula $C_3H_4N_2$, and prepared by acting slowly upon cold glyoxal with strong ammonia in slight excess. Glycosine is thrown down as a precipitate, and the filtrate, which contains glyoxaline, is boiled with milk of lime (to expel the ammonia), after which it is evaporated to a syrupy consistency, treated with absolute alcohol, and filtered. The liquid so obtained is distilled, yielding pure glyoxaline in a crystalline mass of dazzling whiteness. Glyoxaline melts at 192° F., and boils at 491° F. It is freely soluble in water, alcohol, and ether, and has an alkaline reaction. It acts as a base, and forms salts. It is also the starting point for a series of organic compounds of analogous composi-glycollate and calcium oxalate.

Glyoxyl'ic or **Glyoxalic Acid,** an organic acid having the formula H.CO.COOH, and existing in the unripe fruits of many plants. It may be prepared (along with glyoxal) by oxidizing alcohol with nitric acid. It is a thick, syrupy liquid having a specific gravity of about 1.3, and when allowed to stand over concentrated sulphuric acid it crystallizes in trimetric prisms containing water. Glyoxylic acid is very soluble in water, and can be distilled in a current of steam. It is a monobasic acid, forming crystalline salts called glyoxylates. By oxidizing agents it is converted into oxalic acid; by nascent hydrogen it is reduced to glycollic acid. It has also the properties of an aldehyde, reducing ammoniacal solutions of silver salts, forming a metallic mirror; also unites with alkaline bisulphites. Glyoxylic acid, when boiled with excess of lime water, yields calcium glycollate and calcium oxalate.

Glyp'todon, the typical genus of the extinct glyptodontia, or tortoise-armadillos, of South America. The back was covered by a solid bony carapace, without any movable rings such as the armadillo possesses, so that the animal was unable to roll up into a ball for protection; but the tail was protected by a succession of overlapping bony rings, and the head by a stout bony casque, while there was usually more or less armor on the under side of the body. The legs and feet were short and stout, and had hoofs on the toes instead of claws. The animal was 10 to 12 feet in length.

Gmeiner, John, American Roman Catholic clergyman: b. Bärnau, Bavaria, 5 Dec. 1847. He studied at St. Francis' Seminary, Milwaukee, Wis., was ordained priest in 1870, was professor in the seminary, and later in St. Thomas' Seminary, St. Paul, Minn. In 1899 he became rector of St. Francis' Church, Buffalo, Minn. In 1893 he addressed the World's Parliament of Religions at Chicago on "The Primitive and Prospective Religious Unity of Mankind." His published writings include the volumes: 'Modern Scientific Views and Christian Doctrine Compared'; 'Emmanuel: the Saviour of the World'; 'Mediæval and Modern Cosmology.'

Gmel'inite, mĕl'-ĭ-nīt (for Prof. Charles Gmelin), a native hydrous silicate of aluminum, calcium and sodium, crystallizing in the rhombohedral system, usually with a hexagonal aspect. It is colorless or white, often with tinges of yellow, green or red, and transparent to translucent, with a vitreous lustre. It is brittle, with a hardness of 4.5 and a specific gravity of about 2.1. It loses much of its water of crystallization when heated in a closed tube, and dissolves in hydrochloric acid, with separation of free silica. Gmelinite occurs in the Harz Mountains, in Cyprus, and in parts of Italy and Ireland. It is also found at Cape Blomidon and at other points along the coast of Nova Scotia, and fine white crystals of it occur at Bergen Hill, N. J. The mineral was formerly called "hydrolite."

Gnadenhütten, gnä'dĕn-hüt-tĕn, **Massacre at.** For the westward retreat of the Delawares, and their partial conversion to **Chris-**

tianity by the Moravians, see their name. In 1772 their Great Council settled the Christian Indians on the Muskingum in three villages, Salem, Schönbrunn, and Gnadenhütten (Tabernacles of Grace), the latter being that of the Delawares. Through the Revolution these Indians as a body took no part in warfare, quietly cultivating their farms; but some of the younger ones joined the war-bands, which forced the Moravian villages to give them supplies and shelter. The whites were wrought up to frenzy by their atrocities, in which they accused the Christian Indians of being secret participants; and in 1781 a successful foray against the hostiles was only prevented from involving the Moravians by the efforts of Col. Brodhead. But the first blow against them was struck by the wild Indians and British. In the fall of 1781 Capt. Matthew Elliott, under orders from the British commandant at Detroit, with a body of white rangers and a miscellaneous horde of Indians from a half-dozen different tribes, forced them to leave their villages, which were half destroyed; the missionaries were taken to Detroit, and the Christian Indians left on the Sandusky plains, where the wild Indians would have massacred them but for the English. A few escaped and returned to the villages; they were captured by the Americans under Williamson, and taken to Fort Pitt, whose commandant, Gibson, their firm friend and attempted protector, sent them back to the villages unharmed. During the winter the rest suffered much from cold and hunger around Sandusky, and by the spring of 1782 some 150 had returned to the villages. Meantime the fiendish Indian outrages were going on; the borderers accused the Moravians of being privy to them, and denounced Gibson and Williamson for letting them go; and after a woman and child had been impaled alive by an Indian gang, who afterward refreshed themselves among the Moravians, the whites formed a party of near a hundred under Williamson to exterminate the latter. In March they gathered those in Salem and Gnadenhütten into two houses at the latter — those at Schönbrunn had been warned and escaped — under promises of good treatment: a council was held, at which 18 protested against the contemplated murder and withdrew, taking an Indian lad with them; the rest went in and killed the 96 inmates, after the latter had prayed and kissed each other farewell, only two other boys escaping. The best men of the borders denounced the cowardly butchery in unsparing language.

Gnat, năt, a somewhat indefinite term applied to various forms of small two-winged flies, especially those annoying to man and domestic animals. In England mosquitoes are known as "gnats," but in America the term is more restricted to species of the genus *Simulium*, known also as "buffalo gnats," "black-flies," and "turkey gnats," or midges. One of the most remarkable of these species on account of its minute size is the so-called punky or "no see um" of northern woods. The buffalo gnat is quite as bloodthirsty as the mosquito, but is most annoying to domestic animals, including poultry, which are frequently worried to death by swarms of it. These gnats differ from mosquitoes in that they are diurnal, while the latter normally fly by night. The larvæ of most of the gnats, with the exception of the gall and fungus gnats (qq.v.), are aquatic and do no harm in this stage. There is also a distinctive form of gnats which occur throughout the country, but reach their highest development in the Gulf States. The common species are *Hippelates flavipes* and *H. plebejus,* which in Florida occur in great numbers, and are the direct cause of the disease "sore eye" which from time to time becomes epidemic in the rural districts.

Gnat-catcher, or **Gnat-snapper,** any of various little birds that snap up minute insects on the wing. Specifically, in the United States, a small bluish-gray flycatcher (*Polioptila cærulea*), common from Maryland southward, and noted for the exquisite finish of its soft, lichen-covered nest, saddled upon a horizontal tree-limb. See Maynard, 'Birds of Florida' (1872).

Gnathobdellida, năth-ŏb-dĕl'lĭ-da, an order of leeches (q.v.), distinguished by the absence of a proboscis.

Gneiss, nīs, a metamorphic rock, consisting of orthoclase, quartz, and mica. It is akin to mica schist, but contains more orthoclase and less mica; it has the same components as granite, but is stratified or foliated. The geological genesis of gneiss is obscure. One theory is that gneiss is the result of the metamorphism of sedimentary rocks; on this hypothesis gneiss is closely related to conglomerate, which is a mixture of sedimentary pebbles and fine grains resulting from the action of water, while gneiss owes its stratified form to other causes. In some cases this sedimentary theory may hold, but in others it is evident that gneiss is the production of eruptive forces, occurring, as it does, in purely igneous rocks. In the United States gneiss, in the ordinary usage of the term, is common, notably in New England and New York, the strata running northeast and southwest. It abounds in the mountains of central and northwestern Europe and in the ranges of South America. Gneiss is used as a building stone and for flagging.

Gnomé, nō-mā (Gr. "judgment," "advice"), a short, pithy saying, often expressed in figurative language, containing a reflection, a practical observation, or a maxim. Gnomes are a common form of early literature. In religious literature the proverbs of Solomon, those of Jesus, son of Sirach, and the sermon on the mount, are examples. The Sæmundian Edda has preserved excellent proverbs whose authorship is attributed to Odin. The word generally connotes Greek maxims or monitions, and Theognis, Phocylides, and others, are called the Gnomic poets, from their excellence in this sententious manner of writing.

Gnome (nōm) **Owl,** one of the burrowing or "elf" owls of the American plains: specifically, *Glaucidium gnoma.*

Gnomes, in European folk-lore, spirits which dwell in the interior of the earth, where they watch over hidden treasure, and hence are the patrons of miners. Ugliness is their appropriate quality, though the females, gnomides, are beautiful. Among them all Rubezahl (Number-nip) has obtained, by means of Musæus' popular tales, the greatest celebrity in Germany. The native country of these poetical beings is the East, whence they were introduced into Europe

between the middle of the 15th and the beginning of the 16th century by the cultivators of cabalistic philosophy, Pico of Mirandola, Marsilius Ficinus, Paracelsus, Cardanus, and Reuchlin. The gnomes make a part of Pope's machinery in the 'Rape of the Lock.'

Gnomon, nō'mŏn, an astronomical instrument for measuring the altitudes and declinations of the sun and stars. It is usually a pillar or pyramid, erected upon level ground or on a pavement, and is especially used for making the more important observations. Many have preferred it to the smaller quadrants, both as more accurate and more easily made and applied. The most ancient observation of this kind extant is that made by Pytheas, in the time of Alexander the Great, at Marseilles, where he found the height of the gnomon was in proportion to the meridian shadow at the summer solstice, as 213½ to 600. This method of observation was by no means accurate in ancient times, since observers did not take into account the sun's parallax, which makes his apparent altitude less than it would be if the gnomon were placed at the centre of the earth; they also neglected refraction, by which the apparent height of the sun is somewhat increased; and made their calculations as if the shadows were terminated by a ray coming from the sun's centre; whereas it is bounded by one coming from the upper edge of his limb. These errors, however, may be easily allowed for; and, when this has been done, the ancient observations are generally found to coincide nearly with those of the moderns.

Gnomon, in geometry, is the space included between the lines forming two similar parallelograms usually squares, of which the smaller is inscribed within the larger, so as to have one angle in each common to both. For the gnomon of a dial see DIAL.

Gnossus. See CNOSSUS.

Gnosticism, nŏs'tĭ-sĭzm (Gr. γνῶσις, knowledge; γνωστικός, devoted to knowledge), the teaching of various sects in the first Christian century, who hovered on the borderland between Christianity and heathen thought. The systems they founded attempted to grapple with the most profound problems of philosophy, such as the creation of the world and the origin of evil. They taught that a series of divine emanations connected the Supreme Being with the visible universe: that human nature was dual, and that the acts of the body had no influence on the spirit. They blent their ideas of Christian truth with pagan and Jewish elements, or even with those received from the common belief in magic. They taught that the earthly life of Christ was unreal, that is, he was a phantom and incorporeal, and they held that knowledge (γνῶσις) as they possessed it, was superior to faith.

Thus there was a general tendency to trace the same religious idea through different mythologies (which were held to be the popular expression of religious ideas originally revealed), and the new religion which aimed at the redemption of the whole world was eagerly seized on as the embodiment of their unifying principle. Christianity was believed to be the full revelation of the deeper truth embedded in all the nature-religions. By adapting their presentation of Christianity to the form of the ancient mysteries the Gnostic teachers the more easily fastened themselves upon the Christian congregations, and succeeded in taking up a position within them as specially initiated persons, for which they found a natural support in the prevalent ascetic views and the powerful influence of free prophecy. But these were in time forced to separate themselves, and form sects, whose great diversity becoming the more apparent greatly counteracted the influence of the Gnostic leaven in the Christian communities. To maintain their theories in the face of the traditional doctrine of the churches they had recourse to the sources of that doctrine. They claimed to have special traditions from certain of Christ's disciples, and applied their exegetical skill to the allegorical interpretation of the written monuments of the apostolic age. Marcion (about 150), believing himself to be a consistent follower of Paul, rejected the authority of the earliest apostles, as well as the gospels emanating from the circles of their influence, and professed to hold "the gospel" known to Paul only. His collection of 10 epistles of Paul was the first attempt to fix the canon of the apostolic Scriptures. Such arbitrary treatment of the Scriptures led the Church to resort to a more through study of the historical tradition. In the struggle with Gnosticism it obtained a firm hold of the principle that that alone is to be held true Christianity which can be shown to be historically derived from Christ and his apostles, and it found the only means to check the license of Gnostic speculation in the development of a Christian theology in accordance with the positive character of historical Christianity.

The general principles of Gnostic thought may be here summarized, as fuller accounts of the principal schools are given under their own names or under those of their founders. For the practical doctrine of the redemption of men's souls from sin by Jesus Christ the Gnostics substituted a speculative doctrine of the redemption of the human spirit from matter by religious knowledge. The realistic eschatology of the primitive Church they entirely set aside. The evangelic element in their teaching was obscured by a cloud of heathen mythologies and philosophic subtleties. The Divine Demiurgos and Lawgiver of the Old Testament was distinguished from the Supreme Being, and the Hebrew idea of creation was superseded by that of a continuous process of emanations from the divine first cause. The present world was believed to be the result of a catastrophe in which the spirit fell under the power of matter, or of an original destiny that powers hostile to God should bring into existence a world in which the spirit born of God should be held in unwilling estrangement from him. All the Gnostic systems are more or less dualistic. In these dualistic theories a philosophical foundation was secured which was by the Gnostics developed to an extreme. The highest duty of man was to become united to the First Source of Spirit through *gnosis* and the absolute alienation of the human spirit from the body. Others, like Carpocrates and his son Epiphanes, expressed their contempt for the flesh and the ordinances of the Demiurgos in unbridled license. The contrasts of the flesh and the spirit and of the world and the kingdom of God are interpreted as the physical conflict of vast cosmic forces,

and are thereby stripped of their moral and religious significance. The intervention of Christ is the crisis, not only of the religious history of mankind, but of the whole development of the universe. As the final and perfect Æon he is distinguished from his visible manifestation. This is held to be (1) a real human life with which he was connected for a time, or (2) a heavenly or "psychical" creation, or (3) a mere phantasm. Men are divided into two classes: the Pneumatic or "spiritual," who are constitutionally receptive of Christ's revelation and life everlasting, and the Hylic or "material," who are doomed to perish. Valentinians and others add a third, or intermediate class, the Psychical, or men of "soul," who are not capable of apprehending a divine revelation, but only of the popular faith (*pistis*), yet thereby may attain to a degree of knowledge and salvation.

The 'Pistis Sophia,' edited by Schwartze and Petermann (Berlin 1853), is the only Gnostic work that has come down to us in a complete form, except those apocryphal Gospels and Acts of the Apostles which show a Gnostic tendency. Tatian's 'Diatessaron' was used in the Syrian Church down to the 5th century. The Gnostic Bardesanes of Edessa, one of the last of the Syrian Gnostics, was the founder of Syrian hymnology. See Mansell, 'Gnostic Heresies'; Neander, 'Genetische Entwickelung der vornehmsten gnostischen Systeme' (1818); Möller, 'Kirchengeschichte,' Vol. I. (1889); Renan, 'Origines du Christianisme'; King, 'The Gnostics and their Remains' (1887).

Gnostics, a religious philosophical sect, who boasted of a deeper insight into the origin of the world, and of the evil in the world, than the human understanding, so long as it remains in equilibrium, can deem admissible, or even possible. Simon the magician, of whom Luke speaks in the Acts of the Apostles, was the first among them. Even in his dogmas we discover the traces of ideas which were common to all the Gnostics. They may be reduced to the following principal heads: The world and the human race were created out of matter by one æon, called the *demiurge*, or, according to the later systems of the Gnostics, by several æons and angels. The æons made the bodies and the sensual soul of man (*sensorium, psyche*) of this matter; hence the origin of evil in man. God gave man the rational soul; hence the constant struggle of reason with sense. What are called gods by men (for instance, Jehovah, the God of the Jews), they say, are merely such æons or creators, under whose dominion man became more and more wicked and miserable. To destroy the power of these creators, and to free man from the power of matter, God sent the most exalted of all æons, to which character Simon first made pretension: he was followed in these pretensions by Menander, a Samaritan, the most celebrated of his scholars, who, toward the end of the 1st century, founded a sect at Antioch in Syria. Simon and Menander were enemies to Christianity. Cerinthus, a Jew, of whom John the Evangelist seems to have had some knowledge, combined these reveries with the doctrines of Christianity, and maintained that the most elevated æon, sent by God for the salvation of man, was Christ, who had descended upon Jesus, a Jew, in the form of a dove, and through him revealed the doctrines of Christianity. In the 2d century, during the reign of Hadrian and both the Antonines, these principles were adopted by certain Christian philosophers, who are more particularly known under the name of Gnostics, and still further refined, extended, and systematized. Saturninus, a Syrian, speaks of an unknown supreme God, who had generated many angels and powers; seven of these æons were, according to him, creators of the world, and soon fell from God; one of them, the God of the Jews, had seduced man to him, whence originated the difference between good and bad men. Saturninus also calls Christ the Saviour sent by God, and the Son of God; but the opinion that Christ was not actually born, and had not a real human body, but only an incorporeal image, is peculiar to him, on which account his followers and other later Gnostics who agreed with him in this respect were called *Docetæ* (from Greek δοκεῖν, to seem) and *Phantasiasts.* The system of Carpocrates, an Alexandrian, who also flourished during the reign of Hadrian, was distinguished from the one which we have just described in this respect only, that he considered Christ as a mere man, whose purer and more powerful soul had more accurately remembered what it had seen with God before its union with the body. The fathers of the Church, Clement of Alexandria, Irenæus, Eusebius and Epiphanius, from whom, in general, we derive all our information concerning the Gnostics, accuse the moral system of Carpocrates of destroying all distinctions between good and evil, and inculcating an unlimited indulgence of the sensual appetites. Certain it is that his followers practised the most detestable vices, and were the cause of many of the calumnies of the heathen writers concerning the Christians of this century. The Valentinian party, which rose toward the middle of the 2d century in Rome, and especially in Cyprus, and which was distinguished by its austere manners, was the most numerous of all the Gnostic sects, and continued until after the commencement of the 4th century. Marcion of Sinope, and Cerdo, a Syrian, renounced many of the absurdities of the earlier Gnostics, and formed a regular system, the characteristic of which was the rejection of the Old Testament. Bardesanes, a Syrian, and Hermogenes, an African, who, in the reign of the Emperor Commodus, apostatized from Christianity and established sects, bordered, in their hypotheses concerning the origin of good and evil, upon Gnosticism. On the whole, when we take into consideration the philosophical tendency of that age, the passion for the marvelous that had taken possession of the effeminate nations of the Roman empire, and the custom of pretending to a deeper insight into the secrets of nature and the divinity, it is not to be wondered at that a religious philosophy which adopted the most brilliant parts of Platonism, and which afforded nourishment alike to the imagination and to the vanity of secret wisdom, should have met with such universal success. By the austerity of its precepts, and its care for the well being of the soul, it even prepossessed good men in its favor. The Gnostics were the Pietists of the 3d and 4th centuries. The Roman Catholic Church took

occasion from their heresy to give greater precision to the articles of the orthodox faith. There have been no Gnostic sects since the 5th century; but many of the principles of their system of emanations reappear in later philosophical systems, drawn from the same sources as theirs. Plato's lively representation had given to the idea of the Godhead something substantial, which the Gnostics transferred to their æons; and Leibnitz's 'Effulgurations of God,' Ploucquet's 'Real Presentations of God,' St. Martin's 'Pictures and Mirrors,' and the like, as well as the Gnostic æons, are a proof that the essays of the human understanding to explain the creation and the origin of imperfect beings from the perfect always end in similar results. See GNOSTICISM.

Gnu, nū, a Hottentot name of one of the two species of wildebeest. The wildebeests are African antelopes, forming the genus *Connochetes.* The white-tailed gnu or "horned horse" (*C. gnu*) resembles, in form, partly the horse, partly the buffalo, and partly the stag. It is as large as a middle-sized horse, and its neck is adorned with a stiff erect mane. On the forehead the face is covered with an oblong tuft of stiff black hairs, turned upward. Beneath the lower jaw is also a thick, shaggy beard. The legs are long, and elegantly formed, like those of the stag; the space between the fore-legs is covered with long bushy hair. The tail is long and white. The horns are rough, and are enlarged at their base like those of the buffalo; they spring from the hinder part of the head, and, after bending forward beyond the eye, turn suddenly upward. Both sexes are furnished with these appendages. In the young animal they are perfectly straight, acquiring their flexure as the animal grows older. The gnu is affected by the sight of scarlet, like the buffalo or bull. When irritated, it expresses its resentment by plunging, curveting, tearing the ground with its hoofs, and butting with its head. The flesh is juicy, agreeable, and nourishing. This animal was formerly widespread and numerous, roving in small bands with zebras, etc.; but it is now nearly or quite extinct.

Another species, whose habitat was north of the Zambesi, has still escaped extirpation in the interior. It is named *C. taurina,* and has no long hair in front between the fore-legs; there are dark stripes on the sides, and the tail is shorter and black. Consult: Bryden, 'Nature and Sport in South Africa' (London 1897); Millais, 'A Breath from the Veldt' (1895); and the writings of South African sportsmen travelers from Gordon-Cumming (1850) onward.

Goa, a Tibetan gazelle.

Goa Powder, a substance found in the wood of the *Andira araroba,* a leguminous tree growing in Brazil and the West Indies. It derives its name from Goa, a Portuguese colony on the southwest coast of British India, to which it was imported from Bahia for the first time in 1852. It has a bitter taste, is considered efficacious in certain skin diseases, and is used in the preparation of chrysarobin.

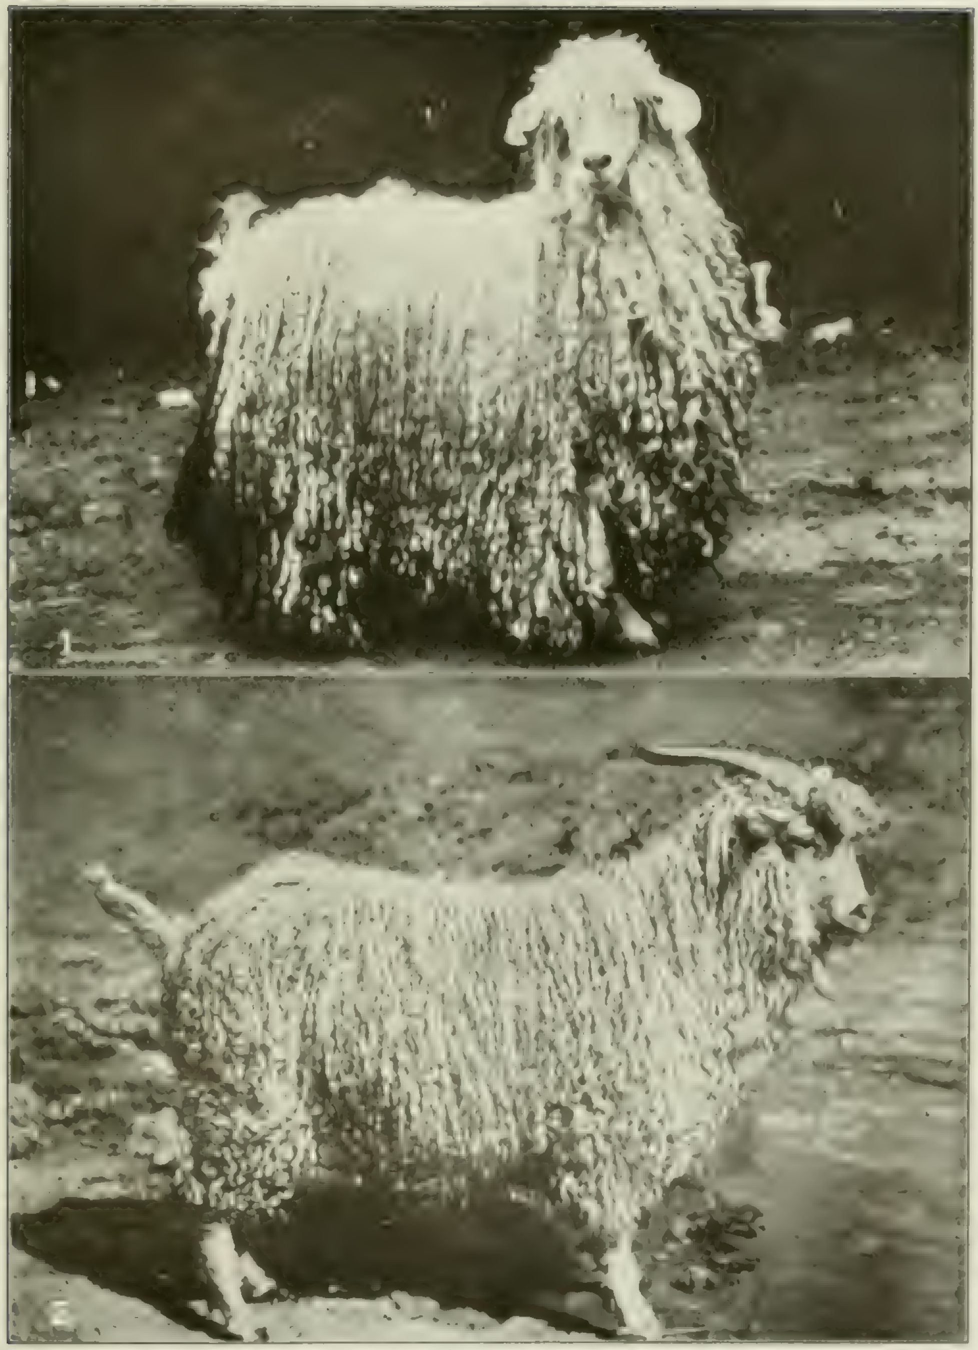
Goajira, gō-ä-hē'rä, a peninsula in Colombia, which forms the most northerly point of South America. It lies west from the Gulf of Maracaibo, or Venezuela, and runs northeast from the Sierra Nevada de Santa Marta to the volcanic Sierra Macuira, which forms its apex, rising to a height of 2,800 feet. The coast is edged with sandbanks, but there is good anchorage at Bahia Honda. Its exports are dyewood, dividivi, pearls, and wood for cabinet work. Up to 1891 Venezuela laid claim to the peninsula, which in that year was formally ceded to Colombia.

Goajiros, gō-ä-hē'rōs, an Indian tribe inhabiting the peninsula of Goajira (q.v.). They are reckoned at 25,000 souls, are subdivided into numberless septs or clans, and for the most part are nomadic, but cultivate the soil and keep flocks and herds (sheep, goats, horned cattle, horses and asses). They also trade in dividivi and fine woods. They are good horsemen, and warriors, arming themselves with bow and poisoned arrows, and are also expert in the use of firearms. They are of fine physical build, especially the women, who are held in high esteem. They wear little clothing, but paint their bodies, and love fine harnesses for their horses. The Roman Catholic mission has been very successful in evangelizing them. Their language is a branch of the Arowak and Maipure group, and connects them ethnologically with the aborigines of the Bolivian Andes, and the plains of the Mahaica and Surinam rivers.

Goat. There is probably no other species of domestic animal that is so widely distributed over the earth as the goat, not excepting the horse, or the cow, or the sheep, yet there is none of them concerning which we have so little scientific information. We are told, however, that there are 10 species of wild goats, all but one of which (the Rocky Mountain goat) are confined to Europe and the Himalaya Mountains. These 10 species are divided into two groups — the ibexes and the goats proper. The ibexes are composed of two sub-species — *Capra falconeri* and *Capra ægagrus.* The *C. ægagrus* is the Paseng, or Bezoar goat, or wild goat, of Persia, and is the progenitor of *C. hircus,* through which are descended all of the domestic goats of all countries. These are numerous in kind and variable in characteristics. Of these only the Angora and the Cashmere breeds and the several breeds of milch goats are of special economic importance, and these only will be treated here.

The Angora Goat.—The history and development of the Angora goat can not be traced to the beginning, but there is evidence that it belonged to a distinctive breed even in the days of Abraham. So far as can be stated definitely at this time, this breed is a native of the vilayet of Angora, in Asia Minor. The capital of the vilayet is Angora, or Eugurieh, the ancient city of Ancyra, where it is believed that the Apostle Paul established one of the western Christian Churches.

The geographical distribution of this breed is not extensive, their raising as an industry being confined to Turkey in Asia, South Africa, and the United States. They have been transplanted to many of the European countries, but without successful result. Australia has had a small number for 50 years, but it is only at the present time that a strong effort is being made to build up an industry of importance there.



1. ANGORA GOAT—YOUNG DOE

2. ANGORA GOAT—BUCK

A few Angoras are thriving in Canada and experiments are being conducted with them in Porto Rico and Cuba. Approximately stated, there are 3,700,000 of these goats in Turkey, 5,000,000 in South Africa, and 800,000 in the United States. At this time they may be found in every State and Territory, including Alaska.

Angoras were introduced into the United States from Asia Minor in 1849 by Dr. James B. Davis, of Columbia, S. C. There were nine goats in this importation, and at that time and for several years later they were regarded as belonging to the Cashmere breed, but one only was a Cashmere, while the remaining eight were Angoras. Several other importations, usually in small lots, have been made from Asia Minor and South Africa. For ten years previous to the outbreak of the Civil War considerable effort was made to exploit the proposed new addition to the animal husbandry of the country, but this failed for various causes, and for many years after the war it seemed that the Angora goats were to prove an absolute failure here. The war had scattered or destroyed nearly all that were in the Eastern and Southern States, but a few that had found their way to California and the Southwest increased rapidly in numbers by crossing upon the long-haired Mexican goats. The redivivus of the industry came about the year 1900, when it was discovered that this country not only had the mills to consume all of the mohair of domestic production, but was also importing over a million pounds annually. The organization in the same year of the breeders into a registry and fair association gave to the industry its first impetus; and then the government assisted largely in exploiting the qualities of the animals. About this time, too, the ability of goats for destroying brushwood became widely known. These two leading features have tended to bring about a rapid growth of the industry.

The Angora goat is small, weighing generally from 60 to 100 pounds, although many may be found in the United States that weigh as much as 140 pounds, and occasionally one much heavier than this. Males and females alike have horns and beards, except that in rare instances one without horns may be seen. The horns of the male grow to a length of 18 to 20 inches and turn upward, outward, and backward, while those of the female, which grow to a length of 8 to 10 inches, grow upward and point backward with only a slight inclination to twist. The ears are usually medium long and pendant, but there are frequent specimens having ears that are short, pointed, and pricked. Except in rare instances, the fleece is pure white, growing to an annual length of 10 inches and covering the entire body down to the knees and hocks. There is no goat odor with this breed except with the bucks at rutting time. The Angora usually has one kid at a birth; twins are not uncommon, and threes are seldom dropped.

The uses of the Angora goat in the United States are three: (1) For the production of mohair (see MOHAIR); (2) for the production of meat; and (3) for the destruction of brushwood and weeds. It is used rarely as a milch animal, owing to the uncertain quantity of milk which it yields.

The uses of mohair are many already and new ones are being invented frequently, so that there has been a constant and increasing demand for this product, with no indication that the supply will ever equal the demand. [illegible] under the head of MOHAIR. The natural result of the many uses of this staple has been an increase in the number of goats and the breeding of animals of better quality. The average weight of the fleece at this time is about 4 pounds, but there are many animals of exceptional merit that will yield 12 pounds and even more, and occasionally a flock that will average 8 pounds per head. A few more years of careful breeding will very likely increase the average per head for the whole country to 5 or 6 pounds. Within the last four or five years, during which time there has been intelligent effort made to increase the quantity of the fleece, there has been marked improvement, and the weight of the average fleece has probably gained 40 per cent. The future should show even better results. The goats yield heavier fleeces in the colder parts of the country than in the warmer sections, and those animals taken from the southwestern States to the northern part of the United States show an increase the first year.

The Angora is the only one of the numerous breeds of goats that yields a carcass that is edible at all ages. The Angora kids, like those of other breeds of goats, are considered a delicacy, and the mature animal is free from the strong taste that is characteristic of other breeds. The size, shape, and quality of the Angora carcass make it so resemble that of the sheep that the packers slaughter large numbers of the low grade Angoras and sell them as sheep mutton. A peculiarity of Angora mutton is that it requires a longer time for cooking than does sheep mutton. In the southwestern part of the country, especially on the large ranches, where it is difficult to keep meat fresh, many grade Angoras are slaughtered for food; but in other parts of the country, where the animals are usually of high grade, they are not generally slaughtered, being regarded as of more value for mohair production.

The predilection of goats for brushwood and weeds is characteristic of all breeds, but the Angoras are considered preferable for this use, because they are able to produce a marketable fleece at the same time they are clearing the land. In many parts of the United States they are regarded as of more value for clearing brushland than any other means. This is especially true where the land is wanted for [illegible] orchards. The total area of land so cleared of brushwood by these goats [illegible] thousands of acres, and their work is done in a most satisfactory manner. The goats feed on every twig and leaf within their reach, [illegible] standing on their hind legs, [illegible] will peel the bark from the [illegible]. If they are again placed on land the second year, so that they may destroy the sprouts that put out from the stumps, their work will be completed, for the stumps and roots then die. As the brushwood and weeds are destroyed [illegible] the grass, [illegible] is indigenous to the locality, will

observed to spring up and thereupon spread rapidly. Where a good variety is not indigenous, a common practice is to sow the seed. This method insures a grass pasture sooner than depending upon the natural grasses and their natural distribution over the cleared area. The goats prefer browsing upon the brushwood to feeding upon the most luscious grasses and clovers and will give the latter very little attention if there is enough of the former to satisfy their hunger. Their presence upon the soil and their indirect assistance in producing the pasture do not make the grass objectionable in any way to horses, cattle or sheep. It should be stated, however, that goats will thrive upon grass and clover if it becomes necessary, and there is no better rough feed for them in winter than clover hay.

The Cashmere goat flourishes in Kashmir, in India, whence it receives its name, and in Tibet. Its color is usually white, and in many other ways it resembles the Angora; but its heavier and outer coat is coarse and not of economic value. Its under coat, called pashm, is very fine and light in weight, and brings very high prices. The amount of pashm produced by each goat annually is between two and three ounces. Most of this fibre is secured by combing the animals when it loosens from the skin, but a considerable amount is picked from the bushes where the animals have rubbed in an effort to remove the sloughing hair. The famous Cashmere shawls, which, a half century and more ago sold at $100 to $2,000, were made of pashm. Dr. Davis brought one Cashmere doe to the United States with his Angora flock in 1849; a buck of this breed died on the voyage. Nine others came in the Brewer importation about 1858. The Cashmeres appeared not to be able to survive the climatic conditions to which they were subjected here, and at this time there is probably not a single specimen in this country. It is not known to the public whether any pashm finds its way to America in the raw state, but it is not likely that it does.

Milch Goats.—No one has attempted to state how many breeds of milch goats there are in the world; one writer says that there are no less than 16 in Switzerland. They are found in their pure state in all European and Asiatic countries and in several of the countries of northern Africa. Specimens of good milking qualities are numerous in South Africa and Australasia, and a very few may be found in the United States. Probably the deepest milker among all breeds is the Nubian, but it is suited to very warm climates only. With reference to their adaptability to our climate and soil, the following are probably of about equal merit: Toggenburg and Saanen of Switzerland, Maltese of Malta, and the Syrian of Palestine. Nearly all of the Swiss breeds are excellent, and also some of those of France and Spain.

In May 1904 there was an importation of 26 Toggenburg and Saanen goats into the United States, and at this time they are thriving well in Massachusetts, New York, New Jersey, and Maryland. So far as any records show, these are the only goats of pure blood that have been received, except four that came in 1893, which did not thrive well; but it is believed that a few kids of Italian goats have been brought here by immigrant families from Italy, and that these have matured and been crossed with the common goats that are usually found in the suburbs of the large cities, thus lending something of their milk characteristics to these latter goats. It is not difficult to find good milkers among these common goats.

A good milch goat should have the same leading characteristics that are possessed by a milch cow. The goat should be level on the back, with slightly dropping hips; the hair, whether long or short, should be kept trimmed close on the udder; the udder should have a shriveled appearance immediately after milking, and the teats should be long and slim.

Milch goats are prolific, seldom having fewer than two kids at a birth, and sometimes four of them. If not restrained they will breed three times in two years.

The quantity of milk that they give varies; a goat that will give two quarts of milk daily for six months is a good milker, but there are many of the best breeds that will yield four quarts a day with a lactation period of six to nine months. Thus it will be seen that, when body weight is considered, the goat is a larger producer of milk than the cow. The milk has a slightly different taste from that of the cow; the strong, acrid taste so often noted by those who have drunk it is due to unclean methods of milking. If the milk is drawn perfectly clean and kept clean, it does not have either taste or smell that is offensive. It is highly regarded in the Old World for its health-giving properties and as a food for children. It is used quite largely in the hospitals in the Swiss and French Alps for tuberculous patients and for those suffering from stomach troubles. The advocates of a milch goat industry in the United States base their arguments principally upon the healthfulness of the milk, although a large use of the goats by the poor in the suburbs of the great cities and in mining districts, it is believed, would prove very economical as well as healthful. Tuberculosis is seldom found in goats, and therefore the germs of the disease, which may be found in the milk of a very large percentage of cows, has never been reported in goat's milk. This fact gives to this milk its highest recommendation.

Kids that are not to be kept for breeding are disposed of for slaughter, and there is a good demand for them among certain classes in the large cities. The flesh is exceedingly delicate, and nothing but the prejudice of people against a matter which they have not tested prevents a larger production and consumption of kids. The kids should be from one to two months old when slaughtered, as after two months the flesh begins to grow tougher and stronger.

Common Goats.—According to the census report of 1900, there are over 1,000,000 common goats — that is, goats of no special line of breeding — in the United States. They can hardly be referred to as an industry, for they have thrived and increased in numbers in spite of neglect. They have been useful in an incidental manner only. A considerable number are used as pets for children, and occasionally a fair milker is found among them. Since the Angoras have demonstrated the ability of the goat to destroy brushwood, the common goats have been brought together in flocks in some

localities and there employed also as brush destroyers. The greater number of common goats are simply tolerated.

Goat-skins.— During the fiscal year of 1904 the United States paid to foreign countries $25,962,620 for goat-skins, not including $4,030,213 paid for gloves, a large part of which was for kid gloves. These importations have been increasing in value annually because of the increased use of goat-skin leather in this country. These imports come chiefly from British India, Mexico, Germany, Russia, and Brazil. With this large expenditure for goat-skins, many persons have thought that the goat-skin industry ought to be developed in the United States, since we have here all that is desirable in the way of climatic, soil, and market conditions; but a recent investigation by an authority in the government service shows that the United States can not compete for this business, for the reason that in all of the countries where the skins are produced in large quantities the wages of goat-herds is a mere pittance, and the carcass, however poor, is consumed for food. These two features preclude a goat-skin industry in this country. However, in connection with the milch goat industry there will be a considerable number of skins, and the prices paid are large enough to pay for caring for them. Goat-skins are used in the manufacture of shoes, gloves, music rolls, morocco for book bindings, etc. The skin of the Angora goat is used as rugs and robes with the hair intact, and also for children's muffs, capes, and for boas for ladies. The leather, like that from all skins having long hair, is not suitable for shoes or fine gloves, but is used largely for workmen's gloves and morocco.

The government, through the Department of Agriculture, has been lending encouragement to the goat industry in all its phases, and its publications on this subject are sent free to all applicants.

George Fayette Thompson,
Bureau of Animal Industry, Washington, D. C.

Goat-antelope, a term applied to certain small mountain-climbing ruminants, which in structure and habits are intermediate between typical goats and antelopes. Such are the white goat of the Rocky Mountains; the chamois of Europe; and the gorals, serows, etc., of the Himalayan and other Oriental mountain regions. For description see their English names.

Goat-fish, one of the gaudy and edible fishes, allied to the surmullets, of the genus *Upeneus*, which abound in the West Indies and Gulf of Mexico, and take their popular name from a fancied likeness of their bearded profile to a goat's. There are several species. The English sometimes call their filefish (q.v.) by this name.

Goat Island, (1) an island in the Niagara River which separates the Horseshoe and American falls. (2) A large island in San Francisco Bay, where there is a lighthouse and government station.

Goat-louse, a parasite living in the hair of goats. It is a biting louse of the genus *Trichodectes*, and that which infests the Angora goat (*T. limbatus*) is often troublesome. Various species occur in various parts of the world.

Goat-moth, a large European malodorous moth (*Cossus ligniperda*), whose caterpillar, the "auger-worm," feeds upon decayed wood, boring a tunnel at the end of which, after three years of growth, it forms a cocoon of chips gummed together by a secretion, and transforms within it.

Goatsbeard, a small rosaceous plant of American woodlands (*Aruncus aruncus*), closely allied to spiræa, with minute white flowers in dense panicles blooming in June, in rich woods of the Mississippi valley, and also on the northern Pacific coast and in Europe and Asia. The name is also given to a saxifrage (*Astilbe biternata*), and to dandelions of the genus *Adopogon* and some other plants.

Goatsuckers, a family of birds, defined under *Caprimulgidæ*, so erroneously named that the term should be abandoned. See NIGHTJAR; NIGHTHAWK; WHIPPOORWILL, etc.

Gobat, gō-bä', **Samuel**, English missionary: b. Bern, Switzerland, 26 Jan. 1799; d. Jerusalem 12 May 1879. After completing a course in Oriental languages in the Mission House at Basel, he became a missionary, going to Abyssinia in 1826 for the English Church Missionary Society. In 1829 he had reached Gondar, but in 1832, upon the outbreak of war in that part of the country, he returned to England. In 1834 he made another journey to the same country, but owing to illness again had to go home. In 1839 he was sent to Malta, where he translated the Bible into Arabic, and in 1845 was appointed a director of the Protestant College. In 1846 Friedrich Wilhelm IV. of Prussia placed him in charge of the See of Jerusalem, an appointment which he held until his death. It was in the orphan schools and hospitals of Jerusalem, Nazareth, and other cities of Palestine that he did his greatest missionary work. He wrote: 'A Journal of Three Years in Abyssinia' (1834).

Gobelin (gŏb-lăṅ) **Manufactory**, a tapestry manufactory at Paris, established by Colbert in 1667. The Gobelin tapestries excel everything of the kind in Europe. Many celebrated paintings of the Italian, French, and Spanish schools have, in the most marvelous manner, been transferred to tapestry. Among the more celebrated of these may be mentioned the portrait of Louis XIV., by Rigaud (the original of which is in the Louvre); 'The Assumption' of Titian, a large work, 23 feet in height; a head by Nicholas Poussin, executed by Marie Gilbert, etc. The first two of these are to be seen in the Gobelin Gallery. All are characterized by splendor of coloring and delicacy of execution. The establishment is now carried on at the expense of the government.

Gobi, gō'bē, **Desert of**, China, the Shamo, or "sand-sea" of the Chinese, an immense tract of desert country, occupying nearly the centre of the high tableland of eastern Asia, between lat. 35° and 45° N., and lon. 90° and 110° E., and extending over a large portion of Mongolia and Chinese Turkestan. Its length is probably about 1,800 miles; mean breadth, between 350 and 400 miles; area, 300,000 square miles. Its general elevation is over 4,000 feet above sea-level. The East Gobi is occupied by different tribes of the Mongolian race, who have numer-

ous herds of camels, horses, and sheep. In the West Gobi are some nomadic tribes of the Tartar race. This tract is supposed at one time to have been a great inland sea.

Gobin, Hillary Asbury, American educator: b. Terre Haute, Ind., 25 March 1842. In 1862–5 he was in the Union army, was graduated from Indiana Asbury College (the present De Pauw University) in 1870, was admitted a licensed preacher of the Northwest Indiana conference of the Methodist Episcopal Church, and held various pastorates in Indiana. In 1880–6 he was professor of the Greek language and literature at De Pauw, in 1886–90 president of Baker University (Baldwin, Kan.), in 1890 became dean of the theological faculty at De Pauw. He was elected president of De Pauw in 1896. His writings comprise articles and reviews in religious and secular periodicals.

Gobineau, gō-bē-nō', **Joseph Arthur, Count de,** French diplomat and author: b. Bordeaux 1816; d. Paris 17 Oct. 1882. He served in the French diplomatic corps in the various capitals of Europe, at Athens in 1868, at Rio Janeiro, South America, and at Stockholm. Chief among his writings are: 'Troi ans en Asie' (1859); 'Les religiones et les philosophies dans l'Asie centrale' (1865); 'Historie des Perses' (1869), etc.

Goblet, gō-blā', **Albert Joseph,** Belgian soldier and statesman: b. Tournai 1790; d. 1873. He participated in the battle of Waterloo, and after the Revolution became minister of war, remaining in that position until he was made minister of foreign affairs in 1832. In 1837 he was appointed ambassador of Spain, a post he held for two years, and it was then that the title of Count d'Alviella was bestowed upon him by the Queen of Spain. In 1843 he was again appointed minister of foreign affairs and for two years in this capacity, his influence on all public matters was felt to a marked degree. He also planned the fortifications along the frontier of northern Belgium, and extended those already built around Antwerp. He wrote: 'Des cinq grandes puissances de l'Europe dans leurs rapports politiques et militaires avec la Belgique' (1863); 'Dix-huit mois de politique' (1865), etc.

Goblet, D'Alviella, Eugène, Count, Belgian archæologist and religious historian; b. 1846. He became professor of the history of religions at the University of Brussels, afterward being elected a Liberal member of the Belgian Chamber of Deputies. In 1892 he was elected to the Senate. After traveling through the Sahara Desert he began his writings, the more important of which are: 'Sahara and Lapland' (1875); 'Inde et Himalaya'; 'The Contemporary Evolution of Religious Thought in England, America, and India' (1885); 'The Migration of Symbols' (1894); and 'Ceque l'Inde doit à la Grèce' (1897).

Goblet, René, rĕ-nā gō-blā, French statesman: b. Aire-sur-la-Lys, 26 Nov. 1828; d. Paris, 13 Sept. 1905. He practised law at Amiens, and entering in 1871 the National Assembly, identified himself with the left Republican group, and became known as an orator, particularly through his part in the discussion respecting the revision of the pension-list for officials under the empire. In 1882 he became minister of the interior, in 1884 of education, and in 1885 of education and public worship. Prime minister in 1886–7, he was minister of foreign affairs in 1888–9, was elected senator in 1891, and sat in the Chamber of Deputies as a Radical in 1893–6.

Goby, gō'bĭ, any one of the 400 species of fishes belonging to the family *Gobiidæ*. They are small carnivorous animals, occurring chiefly on the bottoms of tropical seas and ponds. Most of the species have the ventral fins united into a sucking disk. Most interesting of the gobies are the mud-skippers (*Periophthalmus*) of the western Pacific, which hop about the shores by aid of their pectoral fins, feeding upon insects and naked mollusks. Many of the gobies make nests for their eggs.

God, the Supreme Being, the First Cause, and as considered nowadays throughout the civilized world, a spiritual being, self-existent, eternal and absolutely free and all-powerful, distinct from the matter which he has created in many forms, and which he conserves and controls.

There does not seem to have been a period of history where mankind was without belief in a supernatural author and governor of the universe. The most savage nations have some rudimentary ideas of God. Man is a religious as well as a rational animal. The instinct of belief in God is asserted by philosophical theists to be reconcilable with reason, although no competent apologist now stakes the existence of God on any one argument, or exhibits the proof as a series of syllogisms. It is rather maintained that the study of human history, of human nature especially on its moral and spiritual side, and of the world as far as science reveals it to us make for the existence of a God, demand such a postulate as the key to the universe, and render the belief in a personal God greatly more probable than any other thesis — a subject vastly too wide for discussion here. But it is necessary to name what are often referred to as the four great arguments for the existence of God.

(1) The *ontological* argument first formulated by St. Anselm proceeds from the notion of a most perfect being to infer his existence; without actual existence the idea would fall short of perfection. The argument was re-stated in a different shape by Descartes (q.v.) and by Samuel Clarke, and, though very contemptuously treated by Kant, is still an element of the argument that without a God the world is a chaos.

(2) The *cosmological* argument, employed by Aristotle, Aquinas, and a host of Christian authors, is an application of the principle of Causality (q.v.). We cannot conceive an infinite regression of finite causes; therefore beyond the last or first of the finite causes is the Infinite. From motion the argument is to a mover.

(3) The *teleological* argument, or argument from design, proceeds from the order and arrangement of the universe, the reign of law and beauty and adaptation, to the intelligent and supreme fountain of order. This is the most familiar of the arguments, especially on the lines laid down by Paley.

(4) The *moral* argument was that relied on by Kant (q.v.) when he destructively criticised the other three, and forms a part of most modern theistic arguments. God is a postulate of our

moral nature: and the moral law in us implies a lawgiver without us.

God, Name of, in Different Languages, may be seen from the following list: Elohim, Hebrew; Gott, Swiss and German; Eilah, Chaldaic; Goed, Flemish; Eleah, Assyrian; Godt, Dutch; Alah, Turkish and Syriac; Alla, Malay; Goth, Teutonic; Allah, Arabic; Gude, Danish and Swedish; Teut, old Egyptian; Teun, new Egyptian; Gude, Norwegian; Teuti, Armarian; Bogo, Polish; Theos, Greek; Bung, Pollacca; Jubinat, Lapp; Sire, Persian; Magatal, Tartar; Deus, Latin; Diex, Latin, low; Diu, Gallic; Dieu, French; Dios, Spanish; Deos, Portuguese; Diet, old German; Dieu, Provençal; Doue, low Breton; Dio, Italian; Dia, Irish; Deu, Olala tongue; Theos, Cretan; Jumala, Finch; As, Runic; Fetiyo, Zemblian; Istu, Pannonian; Rain, Hindostanee; Brama, Coromandel; Prussa, Chinese; Goezur, Japanese; Zannah, Madagascar; Puchecammac, Peruvian.

God Save the King (or **Queen**), the burden and common title of the English national anthem. Concerning the author and the composer opinions differ. It has been asserted that Henry Carey, who lived about the middle of the 18th century, was both; but, being ignorant of the rules of composition, employed Dr. Thornton, of Bath, or, according to some, Christopher Smith, Handel's clerk, to correct his rough draught, and add the bass. This story gave rise to the assertion that Handel was the composer. It appears to have been first published, together with the air, in the 'Gentleman's Magazine' in 1745, when the landing of the young Stuart called forth expressions of loyalty from the adherents of the reigning family. After Dr. Arne, the composer of "Rule Britannia," had brought it on the stage, it became very popular. According to a notice in the 'New Monthly Magazine,' Vol. IV. page 389, there is a copy of this national song, published without date by Riley and Williams, in which Antony Young, organist in London, is called the author of the air. There is also a story that this national song, as Burney, the author of the 'History of Music,' mentioned, was not made for King George; but that, in the older versions, it ran thus, "God save great James our king"; and Burney adds, that it was originally written and set to music for the chapel of James II., but that no one dared own or sing it after the abdication of James, so that the song lay dormant 60 years before it was revived for George II. Another account ascribes the air to John Bull, who was organist to the chapel of Queen Elizabeth in the last years of her reign.

Godavari, gō-dä'va-rē, a large river in India. Its source is in the Western Ghauts, about 70 miles northeast of Bombay, and flows southeast into the Bay of Bengal. About 50 miles from the sea the river divides into two channels, the most northern of which flows into Coringa Bay. In the rainy season these branches are navigable, but only for small craft. Before the river divides there are three great obstacles to navigation, caused by three rocky barriers. Between 1861 and 1871 large sums of money were expended by the government on an attempt to open up the navigation of the river by canals going round these barriers, but finally the project was abandoned as involving too great an expenditure.

God'dard, Calvin Luther, American inventor: b. Covington, N. J., 22 Jan. 1820. He was graduated from Yale in 1845 and subsequently devoted his attention to the invention of labor-saving contrivances employed in the wool industry. Among his various inventions of this character may be cited feed rolls for carding machines, a burring picker for the purpose of cleansing wool, and solid packing burring machines.

Goderich, gōd'rĭch, Canada, capital of Huron County, Ontario, port of entry, on Lake Huron at the mouth of the Maitland River, and the terminus of a branch of the Grand Trunk Railway; 119 miles west-northwest of Hamilton, 125 miles west of Toronto. It has a good harbor, steamship lines to various ports, and its people trade largely in fish, salt, and lumber. It is in a good farming district, lumbering and boat-building are important industries, its fisheries are extensive, and large salt-wells make salt refining its chief industry. There are also manufactories of foundry products, machinery, woolens, leather, boots and shoes, wooden ware, etc.; flour and saw mills; and large grain elevators. Pop. (1901) 4,158.

Godet, Frédéric, frā-dē-rēk gō-dā, Swiss theologian: b. Neuchâtel, Switzerland, 25 Oct. 1812; d. 1900. After having been tutor to the crown prince of Prussia, he became in 1850 professor of theology at Neuchâtel. In 1873 he left the state Church and was appointed professor by the Free Church of Neuchâtel. He is best known for his great commentary on St. John's Gospel (1863–5; Eng. trans. 1877), followed by commentaries on Luke (trans. 1875), Romans (trans. 1881), and Corinthians, besides 'Conférences Apologétiques'; 'Études Bibliques' (trans. as 'Old Testament Studies and New Testament Studies' 1875–6); 'Introduction to Paul's Epistles' (1893).

Go'dey, Louis Antoine, American publisher: b. New York 6 June 1804; d. Philadelphia 29 Nov. 1878. He founded the periodical 'Godey's Lady's Book,' the first of the kind in the United States, at Philadelphia, in 1830, and continued its editor and proprietor until its sale to a stock company in 1877. His other publications included 'Jarvis' Musical Library,' and the *Daily Chronicle.*

Godfather and **Godmother** (also, in infant baptism, called sponsors), the persons who, by presenting a child for the sacrament of baptism, and taking upon themselves the vows of faith and obedience, as proxies for the child, and in the name of the child, are reputed to contract toward the newly baptized the relation of spiritual parentage. In the Roman Catholic Church this spiritual relationship is regarded as a species of kindred (whence the name gossip or Godsib, "spiritually akin"), and constitutes an impediment of marriage between the sponsors upon the one hand and the baptized and the parents of the baptized on the other. Anciently,

this impediment arose between the sponsors themselves; and it still extends much further in the Eastern than in the Western Church, although in the former it can arise only from baptism, whereas in the Roman Church the candidate for confirmation also is presented by a sponsor, though usually one of the same sex.

In the Church of England, by whose rule two godfathers and a godmother are required at the baptism of a male, and two godmothers and a godfather at that of a female, no impediment of marriage arises from the relation of the sponsors to the baptized. The parents of the baptized are not permitted to act as sponsors in the Roman Catholic Church, one of the objects of the institution being to provide instructors in case of the death of parents; but the rubric of the American Prayer-book does so allow.

The institution of sponsors was very ancient, and Tertullian (192 A.D.) speaks of the promises made by sponsors in baptism. In the early Church no more than one sponsor was required, a man for a man and a woman for a woman. In adult baptism, the godfathers and godmothers are not sponsors, but only "chosen witnesses," as the person to be baptized takes the vows himself and in his own name.

Godfrey, Elizabeth. See BEDFORD, JESSIE.

God'frey, Thomas, American poet: b. Philadelphia, Pa., 4 Dec. 1736; d. near Wilmington, N. C., 3 Aug. 1763. He is remembered as being the author of 'The Prince of Parthia' (1759), a tragedy, considered to be the first drama published in the United States. In 1763 appeared 'The Court of Fancy; a Poem,' and in 1767 his poems were collected in a volume by his friend, Nathaniel Evans.

Godfrey, Thomas, American mathematician and mechanician: b. Philadelphia 1704; d. December 1749. He was a glazier in his native city; but accidentally meeting with a mathematical treatise, was delighted with the study, mastered all the books on the subject that he could obtain, and instructed himself in Latin in order to read mathematical works in that language. He borrowed a copy of Newton's 'Principia' from James Logan, secretary of the commonwealth, and in 1730 communicated to him an improvement that he had made in the quadrant. In 1732 Logan gave an account of the invention to Dr. Edmund Halley, of England. in a letter. No answer was received after an interval of a year and a half, and then the invention of Godfrey was laid before the Royal Society by the botanist Peter Collinson. Meantime, in 1731, Halley had presented a paper containing a full description of an improvement of the quadrant similar to that of Godfrey. The rival claims were investigated by the Royal Society, and it was decided that they were both entitled to the honor of the invention, and a reward of £200 was bestowed on Godfrey. Franklin observed of Godfrey that, like most great mathematicians whom he had met, he was not a pleasant companion, since he expected universal precision in everything said, and was perpetually denying or distinguishing on trifles, to the disturbance of all conversation.

Godfrey of Bouillon, boo-yôṅ, king of Jerusalem: b. Baisy, in the Walloon Brabant, near Nivelles, 1061; d. Jerusalem 15 July 1100. In 1076 he succeeded his uncle in the duchy of Bouillon. He distinguished himself by his heroic courage at the siege of Rome, and the fame of his exploits procured him, in 1095, the command of one of the armies of the first crusade. In 1096 Godfrey, with his brothers Baldwin and Eustace, commenced his march to Constantinople, the meeting-place of the crusading armies. So great had been the difficulties of the way that it was only a short time before Christmas when he reached Constantinople. Here new delays occurred. The Emperor Alexius Comnenus would not consent to allow the crusaders to cross into Asia Minor until the leaders had sworn to give up to him all the lands which they should conquer which had previously belonged to the Roman empire, and to remain his faithful vassals for all time coming. This Godfrey at first indignantly refused to do, but after a long course of hostilities finally yielded to the demands of Alexius. On 1 May 1097 they crossed the Bosporus, and before the end of the year the crusaders encamped before Antioch. The town fell into their hands on 3 June 1098, but the citadel held out much longer. In the following year (15 July 1099) Godfrey took Jerusalem itself, after a five weeks' siege. The infidels were indiscriminately massacred, notwithstanding the endeavors of Godfrey to put a stop to the slaughter. Eight days after the capture of Jerusalem the leaders of the army elected him king of the city and the territory; but Godfrey declined the kingly title, contenting himself with that of duke and guardian of the holy sepulchre. The sultan of Egypt now raised an army of 400,000 men for the purpose of expelling the crusaders, but Godfrey gave him battle in the plain of Ascalon, on which occasion 100,000 men were left dead upon the field. This victory placed him in possession of nearly all the Holy Land. Godfrey now turned his attention to the organization of his newly established government, dying just a year after the capture of Jerusalem. He was buried in the Church of the Holy Sepulchre.

Godfrey of Strasburg. See GOTTFRIED OF STRASBURG.

Godhaven, gŏd'hävn, or **Lieuely,** Greenland, on Disco Island. It is the capital of the Danish Northern Inspectorate. Pop. 220.

Godiva, gō-dī'va, a legendary English heroine. She was the wife of Leofric, Earl of Mercia and Lord of Coventry in the reign of Edward the Confessor. The inhabitants of Coventry having on one occasion offended their master, he punished them by inflicting so heavy a fine that they were unable to pay it. In their distress they appealed to Lady Godiva to intercede for them, saying that if they paid the fine they must starve. Godiva, sympathizing with the people, went to her lord to plead that, for her sake, the tax might be remitted. Leofric, when she persisted in her entreaties, at last said half jocularly and half contemptuously, that he would grant her request if she would ride naked through the town of Coventry. Having first received permission from her lord to fulfil the condition imposed Godiva caused it to be made known on what terms the earl had agreed to relieve the people from the tax, and then proclaimed that on a certain day no one should leave his house before noon, that all windows and other apertures in the houses should be

closed, and that no one should even look out until noon was past. She then mounted naked on her palfrey, rode through the town, and returned; and Leofric, in fulfilment of his promise, and in admiration of his wife's heroism, freed the inhabitants from the burdens he had imposed on them. Only one person, the story says, attempted to look out, and he was immediately struck blind. A mediæval pageant celebrating Godiva's ride was a feature of Coventry fair for several centuries, and an attempt was made to revive the pageant as late as 1883. See Tennyson, 'Godiva.'

God'kin, Edwin Lawrence, American journalist and essayist: b. Moyne, Ireland, 2 Oct. 1831; d. England 20 May 1901. He was graduated from Queen's College and subsequently was correspondent during the Crimean war for the London *Daily News* (1854–6). He came to the United States as correspondent of that journal and after some time spent in travel was admitted to the New York bar in 1858. During the Civil War period he corresponded both for the *Daily News* and the New York *Times*, and in 1865 established 'The Nation,' which was merged with the New York *Evening Post* in 1882. He continued to edit both papers from that date until shortly before his death. He published a 'History of Hungary' (1856); 'The Problems of Modern Democracy'; 'Reflections and Comments'; 'Unforeseen Tendencies of Democracy' (1898). He was an able, forceful writer who often strenuously opposed dominant political tendencies or principles, but whose entire conscientiousness was never disputed. Under his management the *Post* and the 'Nation' acquired a great influence over the more thoughtful members of the community.

Godless Month, the 10th month of the year with the Japanese, so called by them because then the lesser divinities were considered to be absent from their temples for the purpose of paying the annual respects to the celestial Dairi, a word which, in Japanese means "the Great Interior," that is, of the imperial palace, and in a general sense the person of the Mikado, whose title, "King of Heaven" or "Son of Heaven," implies his divine right to such homage.

God'man, John D., American naturalist and medical writer: b. Annapolis, Md., 1794; d. Germantown, Pa., 17 April 1830. In 1813 he entered as a sailor in the flotilla then stationed in Chesapeake Bay, but in 1815 left the service, and commenced the study of medicine. After lecturing for some time at Baltimore in the room of the professor of anatomy in the University of Maryland, and holding a chair of anatomy for a short time at Cincinnati, he settled in Philadelphia as a physician and private teacher of anatomy. His chief work is his 'American Natural History' (1828). He also wrote 'Anatomical Investigations'; 'Account of some Irregularities of Structure and Morbid Anatomy'; 'Rambles of a Naturalist'; etc.

Godmother. See GODFATHER.

Godol'phin, Sidney, 1ST EARL OF, English statesman: b. near Helston, Cornwall, June 1645; d. Saint Albans 15 Sept. 1715. He was an opponent of James, Duke of York, and a supporter of Shaftesbury during the exclusion agitation, but nevertheless continued in office after the accession of James II. On the flight of that monarch, Godolphin voted for a regency, yet was, after the settlement of the crown on William and Mary, made first commissioner of the treasury. During the reign of Anne he was appointed lord high-treasurer of England, and did much to improve the public credit, and check corruption in the administration of the public funds. In 1706 he was made Earl of Godolphin, and four years afterward was obliged to retire from office.

Go'don, Sylvanus William, American naval officer: b. Philadelphia 18 June 1809; d. Blois, France, 10 May 1879. Appointed midshipman in 1819, he was active in the Mexican war, and in the Civil War, in command of the Mohican, with rank of captain, took part in Du Pont's attack on Port Royal (1861). In 1863 he was promoted commodore and in 1864–5 commanded the fourth division of Porter's fleet in the attacks on Fort Fisher. Having commanded the South Atlantic squadron in 1866–7 and the Brooklyn navy-yard in 1868–70, he was retired in 1871 with rank of rear-admiral.

Godowski, gō-dŏv'skē, **Leopold,** Polish-American pianist: b. Vilna, Russian Poland, 13 Feb. 1870. A pupil of the Hochschule of Berlin and afterward of Saint-Saens, he made concert tours in the United States in 1884–5 and 1890–1. In 1895–1900 he was director of the pianoforte department of the Chicago Conservatory, to which post he was again appointed in 1902. His compositions include concert arrangements of well-known works, concert studies, pianoforte works, and songs.

Godoy, José Francesco, hō-sā' frän-thēs'-kō gō-doi', Mexican diplomat: b. Tampico, Mexico, 9 Aug. 1851. He studied law, was admitted to the bar in California, and practised in California and Mexico. He was also active as a journalist, represented Mexico at the San Antonio International Fair (1889–90) and other gatherings of importance, was Mexican *chargé d'affaires* in the Central American republics (1893–6), and became first secretary of the Mexican embassy to the United States in 1896. He wrote various works in English and Spanish.

Godoy, Manuel, DUKE OF ALCUDIA, Spanish noble: better known as the Prince of Peace: b. Badajoz 12 May 1767; d. Paris 4 Oct. 1851. He entered the Guards in 1787, and was admitted to the presence of the queen, whom he at once captivated by his handsome person and pleasing manners. The imbecile king, Charles IV., was as much pleased with him as his spouse, and he was thus established as a favorite. In 1795, as a reward for the part he had taken in concluding peace with France, he was presented with a large landed estate, and made a knight of the Golden Fleece. It was on this occasion also that he was named by the king Prince of Peace. Other honors and largesses continued to shower upon him, till at last the whole power of the Spanish monarchy was concentrated in his hands. As he used it in the promotion of French rather than Spanish interests, he became extremely unpopular, and an outbreak took place in 1808. He in consequence sought an asylum in France, where he employed the influence which he still possessed over the Spanish king to induce him to abdicate in May 1808. Notwithstanding the enormous wealth which he had at

one time accumulated, he lived a long time in Paris in poverty, maintained chiefly by a small pension from Louis Philippe. He was the author of a work published in a French translation made under his supervision (1836–8) under the title of 'Mémoires du Prince de la Paix, Don Manuel Godoy, duc de l'Alcudia.'

God's Truce, a mutual agreement between territorial nobles confirmed and sanctioned by the Church by which war and violence were to be abstained from for a certain period. In the 9th and 10th centuries the empire of Charlemagne had become broken up into small territories, dukedoms, baronies, counties. The right of private war was a settled principle of the times, and dissensions were frequent and bitter. The peasantry and farmers, especially, were sufferers from the ravages of this petty warfare. Even the monasteries, cathedral colleges and seats of learning were not left in peace and everything threatened anarchy and dissolution. It was at this point that the Church stepped in, as the minister of justice and the guardian of moral order. Stern ecclesiastical penalties were fulminated against all who in the reckless feudal warfare should disturb the peace of churches, priests, and tillers of the soil. The Truce of God was instituted and by its provisions no fighting men should go forth to war on certain days. The little border province of Roussilon was the place where this truce was first agreed upon in the year 1027. Fourteen years later the movement had spread over the whole of France, and later it extended to Germany, Italy, Spain, and England. The Truce of God in 1041 provided that peace was to last from Wednesday evening to Monday morning of each week; there was to be no war during Advent and Lent, nor on certain specified holy days; the punishments for contumacy and disobedience were money fines, banishment for a long term of years, and excommunication; protection was specially extended to all women, pilgrims, priests, travelers, merchants, and agriculturists, and also to the farm inplements and live stock of the peasantry. The Peace of God was confirmed by several councils of the Church, more especially by that of Clermont (1095), when Urban II. proclaimed its universal extension throughout Christendom.

Godthaab, gŏt'häb (Danish, "Good Hope"), Greenland, seaport, on the west coast, capital of the Danish Southern Inspectorate. It is the oldest town in Greenland, and was founded in 1721 by Hans Egede, a Norwegian missionary. Pop. 950.

God'win, or **Godwine,** Earl of the West Saxons, an Anglo-Saxon noble; b. about 990; d. 15 April 1053. He assisted Edward the Confessor in ascending the throne, and married to him his daughter Editha. A quarrel afterward arose between him and his son-in-law, occasioned by the partiality of the latter for Norman favorites, and Godwin in consequence headed a rebellion, but was compelled to submit and quit the kingdom. In 1052, however, he returned with an army, forced Edward to enter into negotiations with him, re-established himself triumphantly in his old supremacy, and caused the expulsion from the kingdom of most of the Norman intruders. He was the father of Harold, the last Saxon king.

Godwin, Mary Wollstonecraft, English writer: b. Hoxton, near London, 27 April 1759; d. London 10 Sept. 1797. In 1783 she set up a school with her sisters, with whom she removed to Newington Green, and wrote a pamphlet, entitled 'Thoughts on the Education of Daughters.' Later she produced 'Mary, a Fiction'; 'Original Letters from Real Life,' and the 'Female Reader.' She was one of the first to answer Burke's 'Reflections on the French Revolution,' which answer was followed by her celebrated 'Vindication of the Rights of Women.' She also wrote 'Moral and Historical View of the French Revolution'; 'Letters from Sweden, Norway, and Denmark.' The eccentricity of her theory was equaled by her readiness to put it in practice, which led her first into the indulgence of a romantic but fruitless attachment for the artist Fuseli. She subsequently married Gilbert Imlay, an American, whose desertion caused her to attempt suicide. As this marriage was void, according to English law, she married in 1797 William Godwin, author of 'Political Justice,' etc. See Godwin, 'Memoirs of the Author of a Vindication of the Rights of Women' (1798); Paul, 'Mary Wollstonecraft: Letters to Imlay' (1879).

Godwin, Parke, American journalist: b. Paterson, N. J., 25 Feb. 1816; d. New York 7 Jan. 1904. He graduated at Princeton College in 1834, and having studied law in his native town, was admitted to practice at the bar in Kentucky, but did not pursue the profession. From 1837 to the close of 1853, with the exception of one year, he was the coadjutor of his father-in-law, William Cullen Bryant (q.v.), in the editorial management of the New York *Evening Post.* In 1843, he issued for a time the 'Pathfinder,' a weekly periodical of a literary and political character. While connected with the *Evening Post* he contributed frequently to the 'Democratic Review,' and he also edited 'Putnam's Magazine' for a time. His acquaintance with German literature was exemplified by his translation of Zschokke's tales and of the first part of Goethe's autobiography. Other works of his are: 'A Popular View of the Doctrines of Charles Fourier' (1884); 'Constructive Democracy' (1844); 'Vala, a Mythological Tale' (1851); 'Handbook of Universal Biography' (1851); 'Political Essays' (1856); 'History of France,' 1st vol. (1861); 'Cyclopædia of Biography' (1865); 'Out of the Past' (1870); 'A New Study of Shakespeare's Sonnets' (1900). He has also edited 'The Life and Works of William Cullen Bryant' (1884).

Godwin-Austen, a mountain peak said to be among the highest in the world; in the Mustagh range of the Himalayan system. Its height is 28,250 feet. Distinguished in the records of the great trigonometrical survey only by the sign K2, it was named in 1888 after Lieut.-Col. Godwin-Austen of the Trigonometrical Survey of India.

God'wits, a group of wading-birds allied to the sandpipers but with longer legs and bill, and distinguished from curlews by the straight not decurved bill. They constitute the genus *Limosa,* of which five species are known. All of them are summer residents of the northern

part of the northern hemisphere, but on their migrations reach northern Africa and South America, while one species extends its flight to New Zealand. Our most common American species are the marbled godwit (*L. fedoa*) and the Hudsonian godwit (*L. hæmastica*), both known to gunners as "marlin." They are not nearly so common as are many other shore-birds on the Atlantic coast. In England two other species occur,— the black-tailed godwit (*L. limosa*) and the bar-tailed godwit (*L. lapponica*).

Goepp, Philip Henry, American musician: b. New York 23 June 1864. He was graduated from Harvard in 1884, and was admitted to the bar in Philadelphia in 1888, but turned his attention exclusively to music in 1891, and became active as organist, composer, and instructor. He has published anthems, songs, and part-songs, written some instrumental works yet in MS., and is the author of 'Annals of Music in Philadelphia' (1896); and 'Symphonies and Their Meaning' (1898).

Goes, goiz, **Pero de**, Portuguese colonist: b. Lisbon 1503; d. 1554. He was the leader of De Sousa's Brazilian expedition of 1530, and in 1532 began the successful cultivation of sugar-cane on a plantation not far from the coast of Brazil. Appointed by the king lieutenant to the governor-general, Sousa, he was of great service in the suppression of Indian depredations. It is stated that he carried to Europe (1547) the first specimens of the tobacco-plant seen there.

Goessman, gĕs'man, **Charles Anthony**, American chemist: b. Naumburg, Hesse-Cassel, Germany, 13 June 1827. He was educated at Gottingen, where he was assistant in the chemical laboratory in 1855–7; came to the United States in 1857; in 1857–69 held positions in commercial companies, and in 1866–8 was professor of chemistry in the Rensselaer Polytechnic Institute (Troy, N. Y.). In 1869 he became professor of chemistry in the Massachusetts Agricultural State College, Amherst, Mass., in 1882–94 was director of the State agricultural experiment station there. In 1886–7 he was president of the American Chemical Society. His papers on salt and the chemistry of natural brines, sugar and sugar manufacture, and his experiment station reports, are of particular value.

Goethe, Johann Wolfgang, yō'hän vŏlf'-gäng gē'te, German poet and critic: b. Frankfort on the Main 28 Aug. 1749; d. Weimar 22 March 1832. He attended the University of Leipsic 1765–8 and in 1770 went to Strasburg where he met Herder and familiarized himself with Shakespeare, and in 1771 took his degree. After publishing two dramas anonymously, 'Götz von Berlichingen' in 1773 announced the dawn of a new era in German letters, and in 1774 'The Sorrows of Werther' made him world-famous. In 1775 he accepted the invitation of Duke Carl August and went to Weimar, his home for the rest of his life. His Italian journey, which marked an era in his career, occurred 1786–7. His friendship with Schiller, of far reaching influence in his poet's life, began in 1794, and ended only with Schiller's death in 1805. In 1806 Goethe married Christine Vulpius. For some years after going to Weimar he wrote but little, but his drama of 'Egmont' appeared in 1785, and thenceforward his leisure was devoted to composing, in prose, his great tragedy 'Iphigenie,' recast in verse in 1786; in writing the novel 'Wilhelm Meister'; and in building up his greatest work, 'Faust.' The succession of his works from 1789 forward was 'Tasso,' a drama (1789); 'Metamorphosis of Plants' (1790); 'The Grand Cophta,' a dramatization of the affair of the 'Diamond Necklace'; 'Wilhelm Meister's Apprenticeship' (1796); 'Hermann und Dorothea' (1796–7); 'Elective Affinities' (1808); 'Fiction and Truth' (1811); 'West-Eastern Divan' (1814); 'Wilhelm Meister's Years of Travel' (1821); second part of 'Faust' (1831: the first part had appeared as 'A Fragment' in 1790).

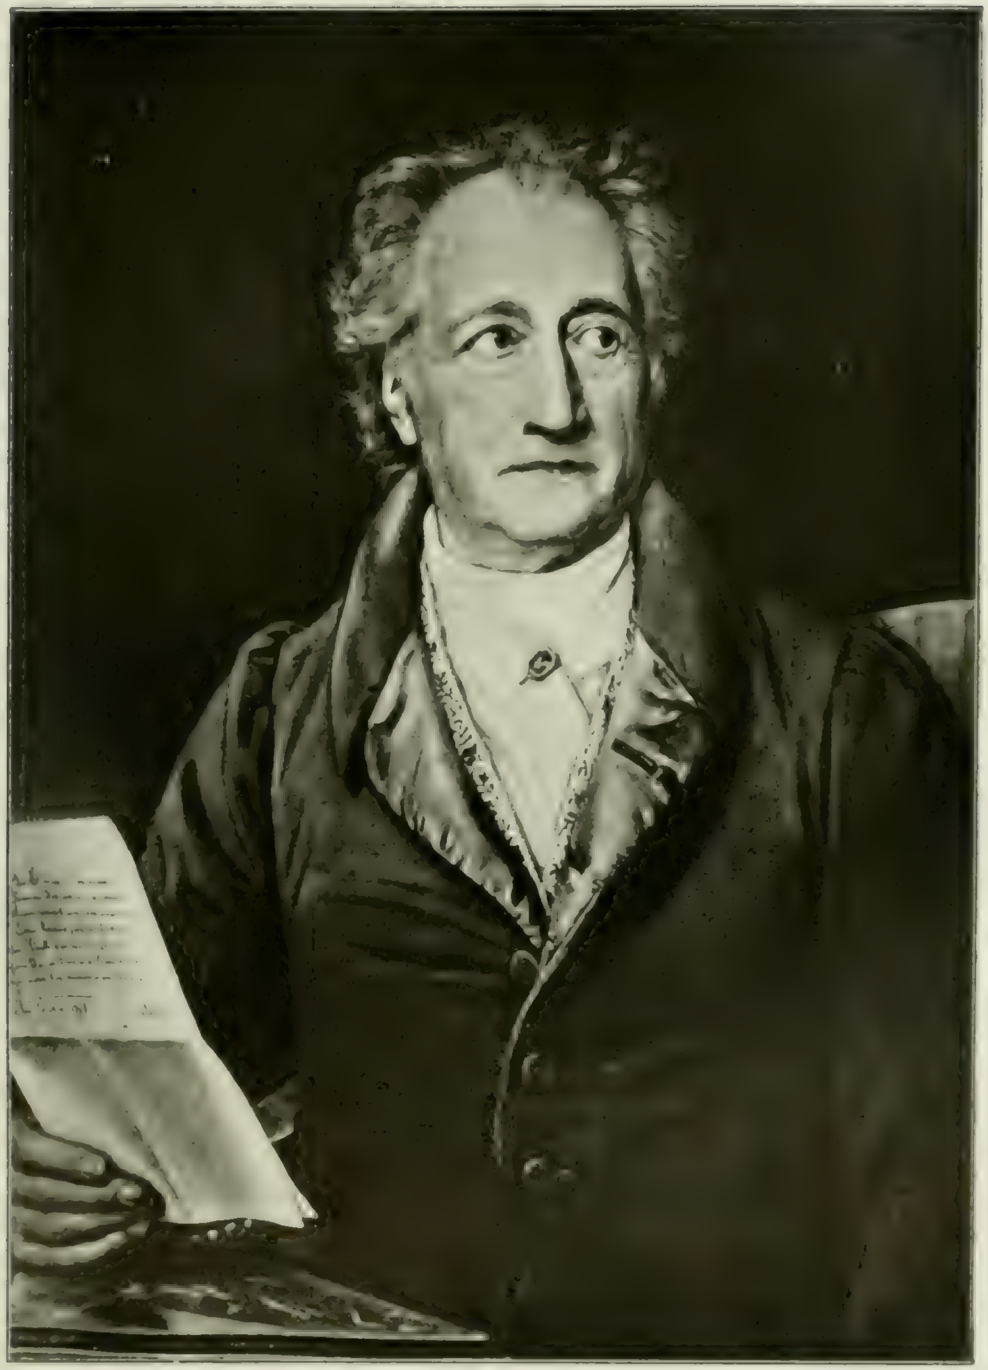
His great life, extending over upward of four-score years, makes him a man of the 18th century and also of the 19th. He belongs not only to German but to European literature. And in the history of European literature his position is that of successor to Voltaire and Rousseau. Voltaire fought to enfranchise the understanding. Rousseau dreamed, brooded, suffered, to emancipate the heart. Here then were Goethe's two great predecessors: one a most vivacious intelligence, the other a brooding sensibility; one aiming at an emancipation of the understanding, but deficient in reverence and in love; the other aiming at an emancipation of the affections, but deficient in sanity of thought. In what relation stood Goethe to these great forces of the 18th century?

In his old age Goethe, speaking of Voltaire, uses the words "a universal source of light." But as a young man he was repelled by him. Into the influence of Rousseau, on the contrary, and into the general movement of feeling to which Rousseau belonged, Goethe in his youth was caught, almost inevitably; and he abandoned himself to it for a time, it might seem without restraint.

Yet Goethe differed from Rousseau as profoundly as he differed from Voltaire. The young creator of "Werther" may seem to have started on his career as a German Rousseau. In reality, "Werther" expressed only a fragment of Goethe's total self. A reserve force of will and an intellect growing daily in clearness and in energy would not permit him to end as Rousseau ended. In 'Götz von Berlichingen' there goes up a cry for freedom; it presents the more masculine side of that spirit of revolt from the bonds of the 18th century, that "return to nature," presented in its more feminine aspects by "Werther." But by degrees it became evident to Goethe that the only true ideal of freedom is a liberation not of the passions, not of the intellect, but of the whole man; that this involves a conciliation of all the powers and faculties within us; and that such a conciliation can be effected only by degrees, and by steadfast toil.

And so we find him willing during ten years at Weimar to undertake work which might appear to be fatal to the development of his genius. To reform army administration, make good roads, work the mines with energetic intelligence, restore the finances to order,— was this fit employment for one born to be a poet? Except a few lyrics and the prose 'Iphigenie,'

these years produced no literary work of importance; yet Goethe himself speaks of them as his "zweite Schriftstellerepoche,"— his second epoch as a writer. They were needful to make him a master in the art of life, needful to put him into possession of all his powers. Men of genius are quick growers; but men of the highest genius, which includes the wisdom of human life, are not speedily ripe. At 26 he was a chief figure in German, even in European, literature; and from 26 to 37 he published, we may say, nothing. But he was well employed in widening the basis of his existence; in organizing his faculties; in conciliating passions, intellect, and will; in applying his mind to the real world; in endeavoring to comprehend it aright; in testing and training his powers by practical activity. A time came when he felt that his will and skill were mature; that he was no longer an apprentice in the art of living, but a master craftsman. Tasks that had grown irksome and were felt to be a distraction from higher duties, he now abandoned. Goethe fled for a time to Italy, there to receive his degree in the high-school of life, and to start upon a course of more advanced studies. Thenceforward until his closing days the record is one of almost uninterrupted labor in his proper fields of literature, art, and science. His task, regarded as a whole, was to do over again the work of the Renaissance. But whereas the Renaissance had been a large national or European movement, advancing toward its ends partly through popular passions and a new enthusiasm, the work which Goethe accomplished was more an affair of intelligence, criticism, conscious self-direction. It was less of a flood sweeping away old dikes and dams, and more of a dawn quietly and gradually drawing back the borders of darkness and widening the skirts of light. A completely developed human being, for the uses of the world,— this was the ideal in which Goethe's thoughts centred, and toward which his most important writings constantly tend. A completely developed State or commonwealth should follow, as an ideal arising out of the needs and demands of a complete individual. Goethe knew that growth comes not by self-observation and self-analysis, but by exercise. Therefore he turned himself and would turn his disciples to action, to the objective world; and in order that this action may be profitable, it must be definite and within a limited sphere. He preaches self-renunciation; the active self-abandonment of devotion to our appropriate work. Such is the teaching of 'Wilhelm Meister': it traces the progress of a youth far from extraordinary, yet having within him the capacity for growth, progress through a thousand errors and illusions, from splendid dreams to modest reality. Life is discovered by Wilhelm to be a difficult piece of scholarship. If we ask,— for this, after all, is the capital question of criticism,— What has Goethe done to make us better? the answer is: He has made each of us aspire and endeavor to be no fragment of manhood, but a man; he has taught us that to squander ourselves in vain desires is the road to spiritual poverty; that to discover our appropriate work, and embody our passion in such work, is the way to true wealth; that such passion and such toil must be not servile, but glad and free; that the use of our intelligence is not chiefly to destroy, but to guide our activity in construction; and that in doing our best work we incorporate ourselves in the best possible way in the life of our fellows. Such lessons may seem obvious; but they had not been taught by Goethe's great predecessors, Voltaire and Rousseau. Sanity for the imagination Goethe found in classical art. The young leader of the Romantic revival in Germany resigned his leadership; he seemed to his contemporaries to have lost the fire and impulse of his youth; his work was found cold and formal. A great change had indeed taken place within him; but his ardor had only grown steadier and stronger, extending now to every part of his complex nature. The change was a transition from what is merely inward and personal to what is outward and general. He did not go into bondage under the authority of the ancients; but he found their methods right, and he endeavored to work as they had worked. For a time the reaction carried him too far. But in the noble drama of 'Iphigenie,' in the epic-idyll of 'Hermann und Dorothea,' and in many of the ballads written during his period of close companionship with Schiller, we have examples of art at once modern in sentiment and classical in method. Goethe's faith in the methods of classical art never passed away, but his narrow exclusiveness yielded. He became, with certain guiding principles which served as a control, a great eclectic, appropriating to his own uses whatever he perceived to be excellent. As in 'Hermann und Dorothea' he unites the influences of Greek art with true German feeling, so in his collection of short lyrics, the 'West-Östlicher Divan' (West-Eastern Divan), he brings together the genius of the Orient and that of the Western world, and sheds over both the spiritual illumination of the wisdom of his elder years. Gradually his creative powers waned, but he was still interested in all — except perhaps politics — that can concern the mind; he was still the greatest of critics, entering with his intelligence into everything and understanding everything, as nearly universal in his sympathies as a human mind can be. The most invulnerable of Goethe's writings are his lyrical poems; against the best of these criticism can allege nothing. They need no interpreter. But the reader who studies them in chronological order will observe that as time went on, the lyric which is a spontaneous jet of feeling is replaced by the lyric in which there is constructive art and considerate evolution. In the poems of the 'West-Östlicher Divan' Goethe returns to the lyric of spontaneity, but their inspiration is rather that of a gracious wisdom, at once serious and playful, than of passion. His period of romance and sentiment is best represented by 'The Sorrows of Werther.' His adult wisdom of life is found most abundantly in 'Wilhelm Meister's Apprenticeship.' The world has long since agreed that if Goethe is to be represented by a single work it shall be by 'Faust.' And even those who perceive that 'Faust' is best understood by being taken along with Goethe's other writings — his early 'Prometheus,' his autobiography, his travels in Italy, his classical dramas, his scientific studies, his work as a critic, his vast correspondence, his conversations in old age — cannot quarrel with the judgment of the world.



JOHANN WOLFGANG GOETHE.

'Faust,' if we include under that name the first and the second parts, is the work of Goethe's whole life. Begun and even far advanced in early manhood, it was taken up again in his midmost years, and completed with a faltering hand in the closing season of his old age. All his works, Goethe said, constituted a great confession. More than any other of his writings, 'Faust' is the confession of his life.

There are two ways in which the reader may deal with 'Faust.' He may choose for his own delight a fragment, detach it and disregard the rest; he may view this fragment, if he pleases, as a whole, as a rounded work of art. Such a reader will refuse to pass beyond the first part of the vast encyclopædic poem. To do this is legitimate. The earliest form in which we possess the drama, that of the transcript made by Fräulein von Göchhausen, is a tragedy which might be named 'The Tragedy of Margaret.' Possibilities of further development lay in the subject, were indeed required by it, and Goethe had probably already conceived certain of them; yet the stadium in the progress of Faust's history included in 'The Tragedy of Margaret' had a unity in itself. But a reader may approach 'Faust' otherwise; he may view it as expressing the complete mind of Goethe on some of the deepest problems of human life. Viewing it thus, he must accept the whole work as Goethe has given it; he must hold in abeyance, at least for a time, his own particular likings and dislikes. While keeping his mind open to all the poetry of 'Faust,' he will soon discover that here is something more than a poem; he finds in it the intellect, the character, the life of Goethe; it is a repository of the deepest thoughts and feelings concerning human existence of a wise seer.

The theme of 'Faust' as originally conceived was the turning of an idealist from his own private thoughts and dreams to the real world; from all that is unnatural,— systems, speculations, barren knowledge,— to nature and the founts of life; from the solitary cell to the company of men; to action, beauty, life, and love. If he can really succeed in achieving this wisely and well, Faust is saved. He is delivered from solitude, the inane of speculation, the vagueness of idealism, and made one with the band of his toiling fellows. But to accompany him there is the spirit of base worldliness, the realist, the cynic, who sees the meaner side of all that is actual, who if possible will seduce Faust into accepting the world apart from that elevating spirit which ennobles actual life, who will try to baffle and degrade Faust by degrading all that he now seeks,— action and beauty and life and love.

It is Goethe himself who is at odds with himself,— the realist Goethe set over against the idealist Goethe; and Mephistopheles is the base realist, the cynic whose endeavor is to mar the union of high poetry and high prose in human life, which union of high poetry with high prose Goethe always looked upon as the true condition of man's activity. Let Mephistopheles, the spirit of negation, try his worst, and at the last discover how an earnest striver's ways are justified by God. Faust may wander, err, fall, and grievously offend,—"as long as man lives, man errs"; but for him who ever strives upward, through all his errors, there is redemption in the end.

See Lives by Schäfer (1851), Lewes (1855), Goedeke (1877), Düntzer (1883), Heinemann (1889), Prem (1900), Witkowsky (1900), Bielschowsky (1902 et seq.); Bernays, 'Der junge Goethe' (1875); Biedermann, 'Goethe Forschungen' (1879–99); Düntzer, 'Zur Goetheforschung' (1891); Zarncke, 'Goethe Schriften' (1897); Weissenfels, 'Der junge Goethe' (1899); Seil, 'Goethe's Stellung zu Religion und Christenthum' (1899); Vogel, 'Goethes Selbstzeugnisse über seine Stellung zur Religion' (1899); Menzel, 'Der Frankfurter Goethe' (1900); Fischer, 'Goethe und Napoleon' (1901); Funk, 'Goethe und Lavater' (1901); Bode, 'Goethes Aesthetik' (1901).

Goethite, gė'tīt, a hydrous sesquioxide of iron, contains when pure 62.9 per cent of iron. It differs from hematite in having a yellow streak and from limonite in containing more water and crystallizing in the orthorhombic system. The lower grade yellow or reddish iron ores of the Lake Superior region, particularly on the Mesabic range in Minnesota, contain considerable goethite and the mineral is thus an iron ore of some importance, though it is not distinguished commercially from limonite. See Iron.

Goetschius, gėt'shĭ-ŭs, **Percy,** American musical scholar: b. Paterson, N. J., 30 Aug. 1853. He was graduated from the Stuttgart Conservatory, became an instructor there, and was appointed to a royal professorship by the king of Würtemberg. In 1890 he received appointment to the professorship of harmony, musical history and advanced pianoforte in the musical department of Syracuse University, and later was professor of composition in the New England Conservatory (Boston, Mass.), from which post he resigned in 1896. He became organist of the First Parish Church (Unitarian) of Brookline, Mass., in 1897. In addition to his compositions, including anthems, sacred songs, and instrumental works, he wrote: 'The Material Used in Musical Composition' (1882); 'The Theory and Practice of Tone Relations' (1892); 'The Homophonic Forms of Musical Composition' (1898).

Goetz, gŏts, **Theodor von,** German painter: b. Lieschen, Siberia, 1826; d. 1892. He began as a genre painter, but in 1848 entered the army and during the Schleswig-Holstein campaigns filled his portfolio with sketches of march and battle. He thenceforward devoted himself to painting military scenes, and became renowned as a battle painter. He took part in the Franco-Prussian war of 1870–1, and painted many striking incidents of the campaign. Noteworthy is his 'Episode in the Battle of Sedan' (1875), one among many remarkable canvases which render him the Horace of Germany.

Goffe, gŏf, **William,** English regicide: b. Sussex, about 1605; d. Hadley, Mass., about 1679. He became a major-general in the parliamentary army, sat in the House of Commons and in Cromwell's 'other House,' and was one of the judges who signed Charles' death warrant. In 1660, with his father-in-law, Gen. Edward Whalley, he fled to America; and they lay in hiding round about New Haven from 1661 to

1664, when they went to Hadley, Massachusetts. There they lived for many years in seclusion; and it is there that, according to the well-known tradition, when the townsmen were called from the meeting-house to repel an Indian attack, and were standing irresolute, Goffe put himself at their head and drove off the foe, and then disappeared as suddenly as he had come. The genuineness of the story, however, has been questioned. His papers have been printed by the Massachusetts Historical Society. See Stiles, 'History of Three of the Judges of King Charles I.' (1794).

Gog and Magog, a king and his nation mentioned in Ezekiel, and the book of Revelations ("the prince of Rosh, Meshech and Tubal from the land of Tubal"). Gog, king of the Magog people, represented the northern hordes, who were to invade western Asia (Ezek. xxxviii. 39). Probably Gog was the Gyges of the Greeks, Gyges being a typical name for kings reigning northwest from the Assyrians. The event predicted was the irruption of the northern nations into Syria.

Gog and Magog are also the names given to two reputed giants of early British history, whose statues are erected in the Guildhall in London. The legend reported by Caxton with reference to these personages declares that they were the last two survivors of the sons of the 33 infamous daughters of the Emperor Diocletian, who, having murdered all their husbands, were sent to sea in a ship, and arriving in Britain and cohabiting there with demons, had a number of giants for their offspring. These giants, it is said, were conquered and brought prisoners to London, where they were kept chained to the gates of a palace on the site of the Guildhall. When they died their place was taken by effigies of them. Effigies called Gog and Magog certainly existed in London at a very early period, and they were sometimes brought out and placed on a conspicuous place to welcome a sovereign entering the city, as was done to Henry V. in 1415; Philip and Mary in 1554; and Queen Elizabeth in 1558. The old effigies were burned in the great fire in 1666. The present figures of Gog and Magog, which are 14 feet high, were erected in 1708.

Gog'gler, or **Goggle-eye,** names given colloquially to several fishes that have prominent eyes, as the rock-bass, the wall-eyed pike, and a tropical crevalle. American gunners call a duck, the surf scoter, "goggle-nose," in reference to spectacles-like spots on its bill.

Gogol, gō'gŏl, **Nik'olai Vassil'jevich,** Russian novelist and dramatist: b. in the government of Poltava 31 March 1809; d. Moscow 21 Feb. 1852. From an early period he manifested a great inclination for dramatic representation, and even endeavored to establish himself in the profession of an actor, but his first appearance was unsuccessful. After filling a situation in a government office, became successively professor of history in the Patriotic Institute, a private tutor, and, lastly, professor of history in the University of St. Petersburg. In none of these did he continue for any time, and presently took up his residence abroad, spending a long period in Italy. His works are extremely popular in Russia for their graphic and humorous delineation of everyday life and manners, and more especially Russian country life. Among them are: 'Evenings at the Farm' (1832); 'Mirgorod,' a collection of tales (1834); 'Dead Souls' (1842), a satirical novel, depicting the public abuses and barbarism of manners prevalent in the provinces; and 'The Reviser,' a satirical comedy of Russian officialdom.

Goitre, goi'tėr, an enlargement of the thyroid gland which may occur sporadically or be endemic. Isolated cases occur the world over. In the United States the disease is comparatively prevalent around Lake Ontario and in parts of Michigan. It is found endemically in the mountainous regions of Switzerland and Italy. The cause is unknown, although certain claims are made that the water is responsible. The symptoms of goitre consist of a more or less uniform enlargement of one or both lobes of the thyroid, causing a puffiness either on one side or both sides of the neck about the region of Adam's apple. When small, no inconvenience is caused thereby, but if the growth becomes extensive, pressure on the important structures of the neck may result in difficulty in breathing, and occasionally sudden death has resulted. Tumors of the thyroid gland such as carcinoma and sarcoma, sometimes simulate goitre. One form of goitre, due to abnormal thyroid function, is known as Graves' disease (q.v.). See EXOPHTHALMIC GOITRE.

Gokcha, gŏk-chä', **Goktscha,** or **Sevanga,** sā-vän'gä, a lake in Erivan, in Transcaucasia, Russia. It is 6,400 feet above the sea and has an area of about 540 square miles. A large number of small streams flow into it, but the outlet, the Sanga, which flows into the Aras, seems to convey only a small portion of the waters to the Caspian Sea.

Golcon'da, Ill., village, county-seat of Pope County; on the Ohio River. It is the trade centre for a large farming country and for a mining district. Its manufactures are chiefly flour and lumber. Pop. 1,200.

Golcon'da, India, an extensive fortress of the Nizam, situated on a granite ridge, seven miles west of Hyderabad, India. In its immediate neighborhood are the ruins of an ancient city, once the metropolis of the powerful kingdom of Golconda, which reached its height at the close of the 16th century and endured till 1687. The place itself is still strong; and about 600 yards distant are the solid mausoleums of its former sovereigns. The fort is held by a small garrison from Hyderabad, and serves as the Nizam's treasury, and also as a state prison. Golconda is proverbially famous for its diamonds; but in truth, they were merely cut and polished here.

Gold (chemical symbol, Au; atomic weight, 187), a metal distinguished from other common metallic elements by its beautiful characteristic yellow color which it preserves untarnished on exposure to the atmosphere under nearly all conditions. Many alloys of copper with zinc, tin, and aluminum have also a more or less golden-yellow color, and are used as substitutes for and imitations of gold, being sold under various fanciful names, such as Dutch metal, Mannheim gold, Abyssinian gold, etc. Some of the bronzes have also a golden color. None of these resist atmospheric action like gold, but some are

fairly permanent under ordinary conditions. Pure gold has a high metallic lustre, but is inferior in this respect to steel, platinum, and silver. The metal possesses a higher specific gravity than any common metal, but is exceeded in this respect by platinum. The specific gravity varies from 19.2 to 19.4, and the metal is thus 1⅔ times heavier than lead and nearly twice as heavy as silver, bulk for bulk. Gold melts at 1045° C., being somewhat less fusible than silver and more fusible than copper. It does not melt in a common fire. At high temperatures the metal is sensibly volatile, and in the intense heat of the oxyhydrogen blowpipe or electric furnace may be vaporized. The vapor is purple.

The pure metal is somewhat harder than lead, but softer than copper, silver, platinum, zinc, or iron. It is consequently too soft, in the pure state, for the purposes to which it is generally applied. For practical application it is alloyed with copper or silver, and both these metals are often present. The former renders the gold redder and the latter paler than its true color. The proportion of gold contained in an alloy is expressed in degrees of fineness, or as "carats" and carat grains (4 grains = 1 carat). The fineness is expressed in parts per thousand, for example 916.6, or decimally, .9166. The carat value of the gold is expressed in parts of 24, pure gold being 24 carats fine. Thus 9-carat gold contains 9 parts of pure gold and 15 of a mixture of copper and silver, etc., commonly known as alloy. Sovereign gold consists of 11 parts gold and 1 copper; guinea gold, of 11 parts gold, ½ part of copper, and ½ part of silver. Standard and guinea gold are thus 22 carats fine (the legal standard for coins in the United Kingdom and colonies), and contain only 2 parts of alloy. The German, American, and Italian standard is 21.6 carat, and is composed of 1 part copper and 9 gold. The following table shows the relative amounts of gold and baser metal in alloys commonly employed:

Carats Fine	Pure Gold	Alloy	Fineness in Thousands
24	24		1000.00
22	22	2	916.66
21.6	21.6	2.4	900.00
18	18	6	750.00
15	15	9	625.00
12	12	12	500.00
9	9	15	37[illegible]
4	4	20	[illegible]

The lowest recognized standard is 9 carat, but much gold of inferior quality is worked up into ornaments and commonly sold as real gold. [illegible] gold is also a common name for this poor material. In the United Kingdom articles of jewelry, plate, etc., are stamped with certain marks known as hall marks, or plate marks, as a guarantee that they have the quality they profess to have. Tampering with hall-marked articles is an indictable offense. Many spurious imitations of hall marks are put upon cheap jewelry, but always differ in some essential feature. Gold alloys of a bad character are frequently colored. This consists in treating the article chemically in such a manner as to dissolve out the base metal constituting the alloy, leaving a covering of purer gold, paler than the original. For this purpose the articles are boiled with 1 part of salt, 1 of alum, 2 of saltpeter dissolved in 4 parts of water, for 20 minutes. Rolled gold is produced by applying thin sheets of gold to a plate of alloy and rolling down the compound sheet.

Pure gold has a tenacity of about 7 tons per square inch, and elongates about 30 per cent before breaking. A wire one tenth of an inch thick will support nearly 200 pounds. Its alloys with copper and silver are stronger. Standard gold has a tenacity of 18 tons (Austen), and extends 34 per cent before breaking. At very low temperatures this is greatly increased (Dewar). Gold is the most malleable of metals, and can be reduced to extremely thin leaves by hammering (see GOLD-BEATING). Such leaves sometimes do not exceed $\frac{1}{250000}$ of an inch in thickness, and transmit green light, though presenting an unbroken metallic surface. This is best seen by mounting on glass. The extreme thinness and high lustre of the metal have led to its use as an illustration of the extreme divisibility of matter. A particle of gold weighing only $\frac{1}{2500000}$ of a grain is readily visible to the naked eye. A grain of gold can be made to cover nearly 80 square inches of surface. The malleability of gold is seriously affected by the presence of minute quantities of arsenic, antimony, bismuth, lead, sulphur, selenium, and tellurium. Of the last 0.2 per cent, and of bismuth 0.5 is sufficient to render the metal crystalline and brittle. Traces of the above elements unfit the metal for gold-beating and coinage. These are removed by passing chlorine gas through the molten metal, or by treating the molten metal with mercuric chloride (corrosive sublimate). By continued hammering the metal is slightly hardened, and must be annealed. Gold surpasses all other metals in respect of ductility. The extreme ductility of the metal is shown by the fact that wires less than $\frac{1}{5000}$ of an inch thick were obtained by Wollaston by encasing a wire of gold in silver and drawing down the compound wire. The silver was dissolved off by treatment with nitric acid. A length of 500 feet of such wire weighs only 1 grain. Gold wire is used for making gold lace. Gold is also extremely flexible and tough. The pure metal breaks with a hackly fracture, but the appearance is greatly affected by impurities.

Chemical Properties.— Gold alloys readily with most metals. It is rapidly attacked by mercury, and dissolves in excess of that metal. If the liquid amalgam be squeezed through wash-leather a yellow pasty mass remains, which may be used in "wash" or "fire" gilding. This process, however, has been largely displaced by electro-gilding, in which the bath consists of the double cyanide of gold and potassium, and is used hot. The metal is unattacked by any of the simple acids, save selenic, but dissolves in any mixture in which chlorine, bromine, or iodine is liberated. The common solvent is aqua regia, a mixture of 1 part nitric acid and 3 or 4 of hydrochloric acid. The chlorine liberated from this mixture converts the gold into the trichloride, an exceedingly soluble body of high tinctorial power, yielding yellow solutions. In the finely-divided state gold is dissolved by chlorine water, bromine water, and iodine solution or tincture, the trichloride, tribromide, and triiodide being produced. It also dissolves in potassium cyanide solutions (in the presence of air) and in cyanogen bromide. These solvents are employed in the extraction of gold from its

ores. Oxides of gold can be prepared with some difficulty. The monoxide is thrown down when caustic potash is boiled with gold chloride solution to which a little acetate of soda has been added. A trioxide (Au_2O_3), a dioxide (Au_2O_2), and a tetroxide (Au_2O_4) are also known. What is known as fulminating gold, $Au_2O_3(NH_3)$, may be prepared by adding ammonia to a solution of gold chloride or by steeping the hydroxide in ammonia. It is a green or brownish powder, which detonates violently when gently heated or when struck. Two classes of gold salts exist. Of the aurous salts, the principal are sodium auro-sulphite, auro-thiosulphate, the cyanide and potassium auro-cyanide. Of the auric salts, the principal are the trichloride and the chlor-aurates. Gold trichloride crystallizes from solution in dark orange-red crystals, $AuCl_3 2H_2O$. It is extremely soluble in water, and volatilizes at 300° in a stream of chlorine gas, but is decomposed on heating to 200° in air with the formation of the monochloride and chlorine, and, at a higher temperature, of gold. It is soluble in ether, naphtha, and essential oils.

The chlor-aurates are combinations of gold chloride with sodium, potassium, and other alkaline chlorides. The best known are $KCl.AuCl_3.2H_2O$, and $NaCl.AuCl_3.2H_2O$, salts commonly sold as gold chloride for photographic purposes. Gold is precipitated from solution by most metals. Iron, copper, and zinc precipitate it readily, generally in a more or less pulverulent form devoid of metallic appearance. Oxalic acid, ferrous sulphate, sulphur dioxide, and sodium sulphite, carbon, grape-sugar, and many organic reducing agents, precipitate the gold from gold chloride. In some cases the metal is so finely divided that it imparts a ruby color to the liquid and does not settle for months. Purple of Cassius is the fine purple pigment produced by treating gold chloride solution with a mixture of tin chlorides, that is, stannous chloride containing a little stannic salt. It is used in glass staining, pottery, and enamel painting, and for coloring artificial gems, imparting a pink, rose, or red color. The addition of tin chloride to the solution obtained by treating an ore with aqua regia and boiling off the excess acid, is a delicate test for the presence of gold. Finely divided gold imparts to pottery and glass a color varying from pink to ruby. Gold resists chemical action to a greater extent than platinum or any other common metal, and in alloys protects base metals from the action of acids to a remarkable extent. Owing to the high specific gravity of gold (19.3) it is possible to roughly determine the richness of the alloy by taking the specific gravity of the article. This is impossible where platinum (specific gravity 21.4) is present in the alloy. The specific gravity of standard gold is 17.157, and of 18-carat gold 16.8.

Assay of Gold.— The touchstone is employed to determine approximately the quality of the gold. It is a hard, black, silicious or flinty slate known also as Lydian stone. Basalt and black Wedgewood ware are also employed. The metal to be examined is rubbed on the stone (any plating or coloring being first scraped off), and the streak compared with that made by needles of known composition differing from each other by one-half carat. The streak is also treated with nitric acid and a test acid, and the result of their action observed. Three or more sets of needles are employed, the chief being a gold-copper series, a gold-silver series, and a gold-silver-copper series. Sometimes five sets are employed, in which the proportions of silver and copper are varied. The series to which the article tested belongs is determined by comparison for color, hardness, and toughness, the latter being inferred from the dryness or greasiness of the streak. The streak is first treated with pure nitric acid (applied with a feather), which is afterward rubbed off. With brass and other spurious copper alloys the streak is completely and instantly dissolved, while poor gold leaves a very faint impression. Nitric acid does not affect any alloy above 15 carats fine. A test acid consisting of 98 parts nitric acid (specific gravity 1.34) and 2 of hydrochloric acid (specific gravity 1.173) is used if the streak has been unaffected by the nitric acid. Gold of 18 carats fine and over is not affected by this mixture in the cold. This method of testing is only used when a rough idea of the richness is all that is necessary for valuation purposes.

Accurate assays of gold alloys are made by wrapping a weighed quantity (either 5 grains or 0.5 gram) in sheet-lead, with sufficient silver to equal three times the weight of pure gold present. Lead to the amount of 34 times the weight of the sample is used for all alloys containing less than 50 per cent of gold, and less for richer alloys. The sample is dropped on to a bone-ash cup (cupel) previously heated to full redness in a muffle furnace. The copper and all base metals in the alloy are oxidized, and the oxides dissolved in the molten litharge formed by the oxidation of the lead added. The fused oxides are absorbed by the porous cupel, thus keeping the metallic surface clear, and at the end of the operation only silver and gold remain behind. After cooling, the button is rolled into a ribbon, annealed, coiled up, and boiled first in nitric acid of 1.16 specific gravity, and afterward in nitric acid of 1.26 specific gravity, to dissolve out the silver, and after washing the coherent cornet of gold is heated to dull redness in an annealing cup and weighed. The addition of silver in assaying is known as inquartation. It is necessary owing to the protective action exerted by gold on other metals.

World Production of Gold.— Gold is very widely distributed, smaller or larger quantities being found in nearly every country. The ancients obtained gold from the Spanish Peninsula, Greece, Asia Minor, and India. The Ophir of the Bible has been variously located. Possibly it was in East Africa. In more modern times Peru, Bolivia, Brazil, Chile, Mexico, and other countries of South and Central America furnished immense supplies of gold after the discovery of America until about 1850. By far the greatest discoveries of gold have been made during the 19th century. The discovery of the Californian placers in 1848, and of the Australian placers in 1851, produced a mad rush to the diggings. In 1858 gold was found in New Zealand, and in 1861 the Otago district became a large producer. Since then immense developments have taken place. Besides California, Montana, Arizona, Colorado, Nevada, Idaho, and others of the United States have furnished, and still furnish large supplies, and Alaska must also be added. British Columbia is an important source, both alluvial and quartz mining being followed. Canada has also entered the lists as

a gold-producer, and the phenomenal discoveries of rich alluvial deposits in the Klondike region in the Yukon basin still furnish excitement. The rich finds in western Australia, in the Calgoorlie and Coolgardie districts, have recently placed that colony in the front rank as a gold-producer, while Victoria, South Australia, and New South Wales have long been large gold-producing countries. In Victoria much energy in the development, more especially of "deep lead" mining, is being put forth. The Witwatersrand district of the Transvaal has sprung into importance since 1886, and Johannesburg is now perhaps the largest gold-mining centre of the world. Russia is also an important producer, the gold being obtained beyond the Ural mountains. India also produces a considerable amount. Of the prospective gold fields the most likely are British Guiana, the hinterland of the Gold Coast, certain parts of China, and possibly East Africa. Gold has been found in several parts of the United Kingdom, principally around Dolgelly, in Merionethshire, in Sutherlandshire, in the Lead Hills, in the Wicklow Mountains, and other places in Ireland. The production of gold in recent years is shown in the tables given below. Such figures, however, are all more or less uncertain:

Country	1896 oz. fine gold	1897 oz. fine gold	1899 oz. fine gold
South Africa...	2,150,106	2,818,403	3,644,880
Australasia ...	2,185,872	[illegible]	3,777,559
Russia	1,041,794	1,121,511	3,164,603
United States..	2,568,132	2,774,935	3,506,679
Other countries	1,874,171	2,075,495	3,081,454
	9,820,075	11,483,712	15,175,184
Value	[illegible]	£48,780,511	£64,309,450

The great increase in the Australian yield is due to the activity in western Australia; in the United States, to Colorado — which now excels California. Canada doubled her output in 1898 — the output being 701,450 ounces. This is due to the Klondike field. The crude bullion from the Transvaal in 1898 amounted to 4,545,014 ounces. In the decade 1831–40 the value of the average annual gold production of the world was £2,831,800; from 1841–50, £7,638,800, the California placers being by this time worked. In the period 1851–5 the average annual value was £[illegible], in 1881–5 only £20,371,777. The phenomenal advance since 1885 is largely due to the development of the Transvaal, but since 1894 the United States, Australia (especially West Australia), and the Klondike region have greatly contributed to the increase: while the cyanide process for treating tailings has led to more perfect recovery of the metal from the ore treated. This phenomenal output of gold — considered along with the fact that much of the ore treated contains only a few pennyweights, and in some cases a few grains to the ton — will give some idea of the enormous amount of capital and energy employed in the search after the precious metal.

Production in the United States. — The following table shows the production of gold in the United States in the calendar year [illegible]:

Alabama	$ 3,900
Alaska	6,9[illegible]
Arizona	4,193,400
California	1[illegible]30,700
Colorado	29,000,000
Georgia	144,900
Idaho	2,273,900
Maryland	200
Michigan	29,000
Missouri	700
Montana	[illegible]
Nevada	[illegible]
New Mexico	[illegible]
North Carolina	65,800
Oregon	1,777,800
South Carolina	[illegible]
South Dakota	6,601,800
Tennessee	200
Texas	1,100
Utah	3,824,300
Virginia	7,400
Washington	620,200
Wyoming	62,000
Total	$80,218,800
British Klondike	17,595,400

The total gold production of the world from the discovery of America by Columbus to the year 1900 is, according to the report of the United States mint, in round numbers, $9,811,000,000. Pure gold of this value would weigh about 16,272 tons, and occupy a space equal to 27,039 cubic feet. Graphically this amount could be represented by a solid circular tower of gold 20 feet in diameter, and 86 feet high. The total yearly world production of gold since 1900 would increase the height of such tower about 3 feet each year.

It has been calculated that the control by England of the African gold mines will result in a largely increased gold supply.

In 1898, the latest complete year before the Boer war, the Witwatersrand, or the "Rand," the Transvaal's principal mining district, produced $60,000,000 in gold. At the rate of increase for the previous few years, maintained through the part of 1800 before the war, the output would have been about $90,000,000 in that year if the conflict had been averted, and more than $100,000,000 in 1900. After mining has been fully resumed, the Rand's annual product, it is estimated by experts on the ground, will soon go up to $100,000,000, and by 1905 or 1906 it will be $125,000,000. It is estimated that that district will yield something like $3,000,000,000 in the next quarter of a century, or before the reef already being worked is exhausted.

There are to-day nearly 1,200 tons of gold in the vaults of the Treasury of the United States — the greatest hoard of the yellow metal ever gathered in the history of the world. Four hundred tons of this gold are piled, like bags of salt, within the four walls of the Sub-Treasury in Wall street, New York. Outside the Treasury hoard there is in circulation through the country a nearly equal amount of gold coin, making more than 2,500 tons of gold in the United States bearing the imprint of the eagle. The total value of this coin is more than $1,260,000,000.

Gold-beaters' Skin, a skin or membrane of great tenacity used in gold-beating (q.v.), and specially prepared from the outer coat of the cæcum of cattle. The intestines of 300 cattle are required to make a single packet or "mould" of gold-beaters' skin, the mould containing about 850 leaves, between which the gold to be hammered out is laid. See Gold-beating.

Gold-beating, the art of hammering gold into leaves of extreme thinness for the purposes of ornamental gilding. For this purpose pure gold is alloyed with small quantities of other

metals according to the color required. Ten colors are recognized: red, pale-red, deep-red, orange, lemon, deep-pale, pale, pale-pale, deep-party, party, besides fine gold. In the deeper colors copper preponderates in the alloy, varying from ½ dwt. to ¾ dwt. per ounce, and no silver. The pale ones contain silver varying from a few grains to 1 dwt. per ounce. The middle ones contain from ¾ to a little over 1 dwt. of alloy, of which ⅔ is silver and ⅓ copper. Ordinary gold-leaf contains about 21 grains of alloy per ounce, and is thus nearly 23-carat fine. The operations are conducted as follows: The metal is melted and cast into ingots, which are rolled out into thin ribands between polished steel rolls. Each ounce of gold is rolled to a length of about 10 feet, the riband being 1½ inches wide and 0.0015 to ,001 inch thick. This is cut up into pieces, each weighing about 6 grains, so that 2 ounces — that is, a "beating" — yields 160 to 170 such pieces. These are packed between intervening sheets of vellum, some 3 inches square, the surfaces of which have been rubbed over with fine plaster of Paris — brime — to prevent the gold from sticking. A number of blank pieces of vellum are placed at the top and bottom of the pile, and the packet is bound with straps of the same material. The cutch thus formed is beaten with a hammer weighing from 17 pounds upward, or by a power hammer, till the gold has been extended to the size of the parchment sheets. The packet is then unbound, the gold squares each divided into four by a steel knife, and the pieces packeted between sheets of gold-beaters' skin (q.v.) about 4½ inches square. A number of blank skins are placed at both top and bottom. The 600 to 700 pieces are all put into the same packet, and comprise what is called the shoder. The shoder is secured by slipping the pile into a parchment band, and again into a similar one at right angles, and is beaten with a round-faced hammer weighing from 9 to 12 pounds, until the gold has extended across the skins. When the gold has filled the shoder each leaf is divided into four pieces with a strip of bamboo sharpened on the long edge. The 2,500 to 2,800 pieces thus obtained are packed in three packets between fine gold-beaters' skin 5 inches square. Each of these packets constitutes a "mold." A large number of blank skins are placed at either side. The packet is secured as before, and each mold is beaten with the "finishing" or gold hammer, weighing from 7 to 10 pounds, till the metal extends to the edges of the skins, and in some places flows over. When the beating is finished the mold is opened. Each leaf is then lifted deftly by long wooden tweezers, placed, with a sudden downward movement, on a leather pad dusted with brime, and from the central part leaves 3⅜ inches square are cut by means of two sharpened bamboo strips fastened parallel to each other. The leaves are placed by the tweezers in books of soft paper rubbed over with red ochre, red bole, and brime to prevent the gold from sticking. If the leaf does not lie flat, a sudden puff of breath, well directed in the centre, lays it flat. Each book contains 25 leaves. Fine gold is more difficult to deal with than that containing a little alloy, owing to its liability to stick when the leaves touch. It, however, beats equally well. The leaf begins to transmit light when $\frac{1}{150000}$ of an inch thick. Ordinary gold-leaf varies from $\frac{1}{200000}$ to $\frac{1}{250000}$ of an inch thick.

Gold Coast Colony, a British crown colony on the coast of West Africa, bounded on the east by Togoland (German), and on the west by the Ivory Coast (French). Its coast line is about 350 miles; its area, inclusive of Adausi, Ashanti, and the Northern Territories, is about 75,000 square miles. Pop. 1,500,000, of whom 500 are Europeans. The native state of Ashanti lies inland, at the back of the central portion of the colony. The territories in the hinterland to the north of Ashanti, were erected into a separate district, the Northern Territories, in 1897 (area 38,000 square miles, pop. 317,964) and placed under the administration of a commissioner. The products are chiefly palm oil, gold, palm kernels, rubber, timber, etc. Chief town, Akkra, pop. 16,267. The government includes a governor, an executive council, and a legislative council of nine, none of whom are elected.

Trouble arose between the king of Kumassi, who had declared himself king of Ashanti in 1894, and the British authorities, and in 1895 an expedition was sent against him, under the command of Sir Francis Scott, which resulted in the submission of the king, who was afterward taken to the coast. The kings of Bekwai and Abodom also made their submission, and the country was placed under British protection, and a resident appointed at Kumassi. The Niger Convention drawn up by the Anglo-French Commission sitting at Paris, and signed 15 June 1898, and the agreement of Germany 1899, settled the boundaries of the hinterland to the west and the north. Bona and Dokta were given up to France, and the French had to concede Wa and other points to the east of the Volta, which had been occupied by them. The railroad from Sekondi to Tarquah was completed 1901, and in 1902 was prolonged 48 miles beyond the latter point. A line is also being laid to the gold mines of Princissu.

Gold-crest, or **Golden-crested Wren.** The British name for one of the Kinglets (q.v.).

Gold Cure, a specific discovered by Dr. Leslie E. Keeley, by the administration of which drunkenness, addiction to such drug habits as taking opium, or cocaine, as well as the tobacco habit are, it is claimed, cured by a renovation of the nerve cells. Dr. Keeley's theory is that all habits of the kind specified above are symptoms of physical disease and disorder, and may be treated like any other affection of the body. Keeley Institutes have been established all over the United States, and there is a Keeley Institute in London. The treatment consists in the administration of bichloride of gold, according to a prescription which has not been made public. According to the testimony of many reformed inebriates of both sexes the results of the Keeley Cure are genuine and lasting. According to the statistics recently issued by the Keeley Institute, the success of the cure extends to all classes. Out of 1,000 consecutive cases treated, 236 were housewives, 150 physicians and surgeons, 50 were without calling, 30 were attorneys, 29 were merchants, 23 were farmers, 20 were dentists; clergymen, authors and actors were also represented.

It takes four to six weeks to accomplish a complete cure, and testimonials are not wanting

from many of the leading men and women in the country as to the efficacy of Dr. Keeley's specific, as they have seen it operating in the case of those who have been submitted to it. "The Keeley League" is an association of 30,000 men who have been cured by the specific and accompanying treatment. The total number which it is claimed have been released from the domination of the drink or drug habit is 300,000.

The discovery was made by Dr. Keeley in 1879, while he was practising physician in Dwight, Ill. In 1880 he opened his first institution at Dwight. The regular medical profession has not accepted with favor the claims of the Keeley Cure.

Gold Hill, Nevada, formerly a distinct village, but now a part of Virginia City. It is about 7,000 feet above the sea. It has rich silver mines, and several quartz mills. Here, on Mount Davidson, is the famous Comstock lode.

Gold Lace, a kind of lace made of gold wire, flattened between two polished steel rollers, into a ribbon which is twisted round a core of silk. The "gold wire" used in the manufacture of gold thread is nearly always composed of pure silver with a thin coating of gold in India. But in European countries it is only the very best qualities of this wire which are made of unalloyed silver. A good quality of English gold thread is made from wire consisting of 1 part of copper added to 25 of silver, which is afterward coated with gold. But alloys of copper and silver in many proportions are used, some wire containing only 1 part of silver to 60 of copper. The silver, or alloy of copper and silver, is made into a rod 1½ inches in diameter, and then annealed and polished to prepare it for its coating of gold. This is laid on in the form of leaves of pure gold, and subjected, for the best qualities of wire, to the fire-gilding process — that is, the gold-coated rod is heated to redness on burning charcoal, which causes the leaf to adhere firmly. Rods so treated are next smeared with wax, and drawn through the holes of a steel drawplate. (See WIRE-DRAWING.) The wire is frequently annealed during the process of drawing, and this requires to be very skilfully done, or the golden tint of the surface is lost. Gold wire for thread is generally drawn down to a size measuring 1,100 to 1,400 yards to the ounce of metal. Finer sizes reach the length of 1,800 to 2,000 yards to the ounce, and to attain this fineness the wire is drawn through perforated gems, such as diamonds or rubies. The fine wire, after being annealed, is flattened between polished steel rollers. Finally the flat wire, or rather ribbon, is wound over yellow or orange colored silk, so as completely to envelop it, by a spinning engine. The gold thread is then finished. Some of the best qualities of the metal covering or "plate" of this thread have 12 pennyweights of gold to the pound of silver or of alloy. Inferior kinds have as little as 2 pennyweights to the pound and still cheaper sorts of thread are covered with flattened copper wire which has received a thin coating of electro-deposited silver, and this afterward receives, on the outside of the thread only, a still thinner electro-deposited coating of gold — two grains of the precious metal covering 3,000 square inches of surface. For this very cheap kind of thread yellow cotton is used instead of silk.

The only difference between gold and silver thread is that the thin coating of gold is wanting on the latter. Gold thread is used in the manufacture of military lace. This, however, is a woven substance and not true lace; but some real lace is made both of gold and silver thread. Both kinds of thread are also used for facings of liveries, and for ecclesiastical robes, altar cloths, and banners. These and other fabrics are either embroidered or woven, but often only in part, with the thread. (See BROCADE; DAMASK; EMBROIDERY.) Much of the "gold thread" used for theatrical dresses and decorations has only a covering of Dutch metal and the "silver thread" in these is spun with a covering of a cheap white alloy, having a mere film of silver on the surface.

Gold Mining. Gold is usually found in nature in the metallic or native state, and may be distinguished from iron and copper pyrites and other yellow metallic minerals by its malleability and softness. Native gold is never pure. Its quality varies from about 800 to 950 fine, or about 20 to 23 carats (see GOLD). Electrum is a native alloy of silver and gold about 500 fine. A native amalgam with mercury also occurs. The metal sometimes occurs crystallized in octahedra and other cubic forms. It is also found in irregular masses which may be nodular, filiform, or arborescent, or it may form thin leaves merely gilding the surfaces of the rock. More commonly it exists in grains irregularly distributed through sand, gravel, or rock. These grains are sometimes so minute as to be invisible to the naked eye, and the presence of gold can only be detected by subjecting the rock to a careful assay, either by grinding with mercury, washing, or fire assay.

The metal occurs in (1) alluvial deposits, or "placers." These are deposits of gravel, sand, clay, or loam, consisting of the debris of weathered rocks, generally transported by running water from hillsides to valleys and plains. They mark and follow the courses of existing rivers or of rivers belonging to former ages. Gold is found in them in all degrees of coarseness, from minute specks or "colors" to masses weighing many ounces. One of these, designated the "Welcome Stranger," found at Dunolly in Victoria, weighed 2,195 ounces troy, and many others of large weight have been found.

These larger masses of gold have usually a more or less rugged and lumpy exterior, and are described as "nuggets." The largest usually occur near the source from which the gold in the alluvium has been derived. This source almost always consists of veins of quartz, or other material, occurring in one of the older rocks. Alluvial deposits vary in character from pipe clay to coarse gravel. The gravel is usually loose, but sometimes in working the deposits intervening layers are met with which are cemented together. These are known as "false bottoms." River sands also frequently contain gold. Alluvial deposits are often very rich, particularly in nuggets. This is largely due to the force of the water carrying forward the light earthy material, while the larger and heavier particles, owing to their greater resistance, accumulate nearer the source. (2) The formation which is known as "deep leads" consists of ancient

river beds that have been covered by more recent deposits of drift, earth, or volcanic rocks, which have become hardened and consolidated. They are composed of sand, gravel, loam, and clay, the so-called "wash-dirt" or "pay dirt" varying from a few inches to several feet in thickness. Formerly these deep leads were the main drainage channels of the country, and in rain storms were heavily flooded, carrying the debris from the hillsides down the creeks and gullies. In Victoria the deep leads are often overlaid with a deposit of basalt known as "bluestone," showing volcanic action to have been instrumental in covering up the deposit. These deposits often extend out beyond the covered portion, and in mining operations trouble is occasioned by water which finds its way in through the exposed portion. Their direction is traced by boring. (3) In the primitive rocks gold occurs generally, though not invariably, in veins of quartz. The terms "lodes," "reefs," "ledges," are also used much in the same sense as veins. The metal is not uniformly dessеminated through the rock, but occurs in most cases in rich streaks and pockets. Careful examination will often reveal its presence, but no general appearance of the quartz can be relied on. Highly mineralized quartz is generally most productive. The minerals usually present are silver, zinc, lead, copper, iron, nickel, bismuth, tellurium, and antimony-bearing minerals, the commonest being iron pyrites, mispickel, zinc blende, galena, copper pyrites, argentite and other silver ores, nagyagite and other tellurides, bismuthine, antimonite, limonite and hematite. Sometimes these — especially iron pyrites — are present in very large quantities. Near the surface this has been completely decomposed and partially converted into oxide of iron, conferring a reddish brown color on the more or less spongy rock. Such decomposed rocks containing much oxide of iron are described as "gossans." In the cavities small particles of free gold can often be observed. In the unaltered portions of the rock the accompanying minerals may be plainly distinguished. The veins may be compact and large, but the mineral streak often occupies only a portion of the lode, though many "leaders" may occur. Much of the lode is sometimes barren. In some quartz deposits the stone is uniformly rich; in others the gold is concentrated at certain points in what are known as pockets. According to a recent report from Cripple Creek, Colo., a mass weighing over a hundredweight with a slight admixture of quartz has been found there. A similar mass of less size was found some years ago in India, and another near Sydney, N. S. W., was 5 feet high, 1 foot wide, and 6 inches thick, full of threads, wires, lumps, and sheets of gold. It realized £15,000. The "banket" ore of South Africa resembles both alluvial deposits and reefs. It consists of a mass of quartz fragments mostly irregular, embedded in a cement of mineralized matter which carries the gold. This, near the surface, is completely "weathered," and an incrustation of oxide of iron remains surrounding the quartz. Strangely enough this deposit resembles a reef rather than an alluvium and extends to great depths. Several "deep" mines are now in operation. No satisfactory explanation can be given of this formation. Ores of other metals frequently contain gold. Iron and copper pyrites, antimonite, galena, and silver ores are often gold bearing. The precious metal is extracted in the smelting of the mineral. Gold occurs also in combination with tellurium and possibly with selenium, as well as in the free state. Most telluric ores are gold bearing, and the presence of this element is often looked on as an indication of gold.

Placer Mining.— When the alluvium is at the surface the exploration of the ground can proceed forthwith, and with pick and shovel the gravel is turned over and the nuggets taken out. The remainder is afterward washed to recover the finer particles of gold, in the pan, the dolly, or the cradle. When the "pay dirt" is covered with soil, etc., the "cover" is first removed to lay it bare, and the washing proceeded with. From the above references the presence of water is a most important item in the satisfactory exploiting of alluvium. The washing of sands and gravels is a simple matter. In washing in the pan —"panning out"— a quantity of the dirt free from the stones is put into a shallow iron or wooden dish some 15 inches in diameter, with a slight depression in the middle. It is then mixed with water, and the dish put with its edge just under water with one side a trifle lower than the other. Any lumps are broken up by hand. By a gentle whirling and jerking motion the sand and other light bodies are washed over the edge of the pan, and the heavy matters containing the gold remain at the bottom and accumulate in the central depression. Pebbles are thrown out, and the "colors" (specks of gold) are then sought after and picked out, or the whole heavy residue saved, dried, and blown, or treated with a little mercury to extract the gold.

The "dolly" or "tossing tub" is intended for washing fine stuff or coarsely crushed material passing through a sieve having 12 meshes to the linear inch. It consists of a circular tub in which the dirt is mixed with sufficient water, and is stirred around with a shovel or other implement three or four minutes. A little of the water is then removed, and the tub struck on its sides for some few minutes with a hammer to quicken the subsidence of the heavy matters. The water is then poured off with the lightest matters, and the upper portions of the remaining mud scraped off and thrown aside. Some fresh dirt is added and the operation repeated. By this means a gradual accumulation of gold takes places at the bottom of the tub — or kieve, as it is called — and is removed from time to time. Some tossing tubs are provided with rotary stirrers.

The "cradle" consists of a short box or trough six or seven feet long, mounted on a kind of rockers, and slightly inclined to allow the mud to run off. A box with a bottom of iron plate perforated with half-inch holes is placed over the higher end of the trough. Underneath this an inclined plate directs the stuff to the top of the trough, across the bottom of which strips of wood called riffles, about half an inch thick, are fixed transversely to arrest the heavy particles of gold. The "pay dirt" is thrown into the box at the top, and water is led into or poured on it. The finer portion is thus carried through the holes into the trough. Lumps are broken up and the cradle rocked from side to side with a jerking motion. The light matters are carried away by the water from the lower end of the trough, and the particles

of gold and other heavy matters lodge behind the bars and are afterward collected.

Sluicing.— This is the method adopted where practicable for treating alluvial deposits. The "sluices" consist of troughs called "flumes," in sections about 12 feet long, mounted on trestles to give a sufficient inclination — from ¾ to 1½ inch to the foot. The lower ends of the troughs fit into the upper ends of the succeeding sections. The bottom of the sluice box is crossed transversely by bars of wood or iron. In long sluices these are about two inches thick and are supported by longitudinal bars, dividing the bottom of the sluice into rectangular spaces. The gravel is placed at the top and washed down by a stream of water, while the lumps in the hand sluices are broken up by raking them.

The smallest of the sluices, known as the "long tom," and worked by two or three men, consists of two such sections. Into the upper one the gravel is thrown, and the lower end is closed by an iron grid set at an angle, to keep back the pebbles and large stones, while the sand, etc., passes through to the lower trough. In this it deposits its gold and heavy matters behind the riffle bars which in these shorter sluices are not so thick. The longer sluices, for dealing with larger quantities of material at a time, are made 250 feet long, or longer in many cases, and if there are many stones in the stuff to be treated, the sluice is divided into two sections, placed at different levels. The lower end of the upper section is not blocked, but near it the bottom consists of an iron grating — the "grizzly." The stones are washed forward over the grating, and fall or are raked out at the end. Under the grating is the second section of the sluice, often arranged at right angles, or to run in an opposite direction and with a smaller inclination. On this the sand and fine particles carried by the water fall, so that the smaller particles of gold may be recovered. In sluicing, mercury is often fed in at the top of the sluice in order to amalgamate the gold, and the amalgam then lodges behind the riffles. In other cases the fine sand, after passing through the first section of the sluice, falls on inclined tables covered with blankets, rough cloth, or hides with the hairy side up, over which it flows in a thin stream. These "blanket strakes" serve to arrest and recover the fine gold. Amalgamated copper plates are employed for the same purpose in some cases, over which the fine sand flows before running to waste.

In dealing with the hard "cements" and "deep leads," the material is generally first treated in a "puddling" machine. In this the pay dirt is disintegrated by edge runners, or revolving rakes or harrows, or some other form of crushing or stirring apparatus, while a current of water carries the debris from the machine into the flumes and over the strakes. Much of the coarse gold remains in the puddling machine. Where the configuration of the ground admits, there is no difficulty in getting the necessary fall, but where the surface is level this has to be obtained artificially, by erecting very high poppet-heads over the shafts from which the pay dirt is drawn. In some cases these are over 100 feet in height, the puddlers being placed on a platform at a suitable elevation, from which the flumes slant downward, being caried on trestles.

Hydraulic Mining.— In places where the ground is suitable, these deep leads and other alluvial deposits are worked by washing down the gravel by means of a powerful jet of water, a head of 200 to 250 feet being sometimes employed. The jet is delivered from a movable pivoted nozzle — the "monitor" or "giant"— against the bank of auriferous material, and the detached debris washed into sluices where the gold is deposited. These sluices are larger than those already mentioned, being sometimes 5 to 6 feet in width, 2 to 3 feet deep, and are often paved with stone and provided with iron riffle bars. Some of them are upward of a mile long. Mercury is always fed in at the top, and the amalgam recovered by raising the riffle bars after turning off the water and cleaning out the gravel. An immense water supply is required for this purpose, and the water is often brought for miles in "flumes" which cross gulches and valleys supported on trestles, and are carried in tunnels through hills. This is the cheapest mode of working. From two to four grains of gold per ton, and in some few cases less, is sufficient to pay expenses. If the material is exceptionally hard, blasting is resorted to in order to break it down, when the action of the jet is sufficient to disintegrate it. A "miner's inch" of water is the quantity that will flow through a hole an inch square in an inch board, under a head usually of 7 inches, but more or less according to the locality, the time of flow being specified. A 24-hour inch at 7 inches pressure is nearly 14,000 gallons. In other cases an inch reaches 17,000 gallons. The river gravels of Scotland, Ireland, and Wales, and many parts of Europe, have yielded gold, but the richest of such deposits are those of California, Klondike, and Australia. Magnetic iron sand, tin stone, ilmenite, sulphides, garnets, and diamonds are often associated with alluvial gold.

Quartz Mining.— In dealing with the material from veins or reefs of quartz and other hard substances containing free gold, the stuff is reduced to fine powder and then passed, suspended in water, over copper plates amalgamated with mercury, to which the gold adheres. The "tailings" are then treated either by "concentration" and the concentrates chlorinated, or the whole of the tailings is treated by the cyanide process. The ore to be crushed is first passed through a "stone breaker" or "ore crusher." In the Blake type the moving jaw permits the introduction of the larger lumps at the top, but only allows the crushed material to pass out at the bottom in pieces a little larger than walnuts. In the Gates type a gyrating cone revolves inside a fixed vertical cone. Both have ribbed surfaces, and they are of different angles, so that the large material introduced at the top is broken down before it can pass out at the bottom. The broken ore passes to the ore bins, thence to the feeders and on to the stamps, or some form of grinding mill. The lower part of the battery consists of a cast-iron box — "mortar box"— fitted on one or both sides with a fine screen of wire-cloth or perforated sheet metal. At the bottom of this box is a row of iron blocks called "dies," on which the stamps fall. The stamps are heavy cylindrical cast-iron blocks — heads — to which are attached loose steel facing pieces —"shoes"— fixed to the lower ends of the vertical iron rods — stems — moving up and down between guides carried by the framing. The stamps are raised by cams keyed on the revolving shaft. These engage with collars

— tappets — fixed on the stems. As the shaft revolves, the cam raises the stamp twice in each revolution and allows it to fall when the cam passes. The stamps are thus kept pounding away at the ore in the mortar box. The heads and their attachments weigh up to nearly half a ton, and make from 70 to 90 blows per minute. Five heads usually constitute a battery. Some mines have 200 stamps at work. Each head should crush about one and a half to two tons of ore per day. The motive power may be steam-engines or turbines. Some mills are driven electrically. In wet crushing mills a stream of water is admitted to the mortar box, and carries the crushed material through the screens. Mercury is fed into the mortar boxes in small quantities, and much of the gold is retained there on amalgamated copper plates. Slightly inclined amalgamated copper plates arranged in steps are placed in front of the battery, and over these the crushed ore pulp passes slowly as it leaves the mortar box, the gold being retained by the amalgamated surfaces. The plate nearest the battery is generally heavily silver plated. The "tailings" which may still contain some gold are treated as described below. The stamp battery is often replaced by roller crushing machines and grinding mills of various types, the objects of which are the same; and with certain ores these are even more effective. The best known of these are Krom rolls and the Huntingdon mill. Steam stamps are also employed, making up to 200 blows per minute.

Treatment of Amalgam.— The amalgam, both that which is retained on plates placed in the battery and that which accumulates on the plates outside, is collected from time to time. The plate just outside on which the splash from the battery falls, is made small so as to be readily removable for cleaning up. The other plates are not so often disturbed. The amalgam is ground with water in a small iron pan with a revolving muller —"clean-up pan"— to cleanse the amalgam from sand, etc. Afterward it is pressed in wash-leather, canvas, or other material to expel the excess of mercury, which is returned to the battery as required. The residue is "retorted," that is, it is heated in retorts to expel the mercury, which is condensed and recovered. The gold obtained is subsequently melted in crucibles and afterward refined. "Free-milling" ores yield nearly the whole of their gold by this treatment. Ores containing sulphides, arsenides, antimony, tellurium, etc., do not, and are described as "refractory ores." Free-milling ores are generally "weathered"; the minerals having been decomposed by the action of the atmosphere and water.

Treatment of Tailings.— Tailings always contain gold, either as "float" gold, "rusty" gold, or bound up in pyrites or other mineral occurring in the rock. Pulp (that is, the crushed rock) containing float gold is led through amalgamating pans, where it is ground with mercury before running to waste. In dealing with pyritical ores, when chlorination or grinding with mercury is resorted to, the pulp is passed to concentrating appliances, blankets, strakes and "vanners" being employed. Vanners are by far the most effective and generally employed. Each consists of a slightly sloping table, formed of an endless traveling belt of india-rubber which is stretched over rollers at the ends of a frame, and so mounted as to be capable of violent agitation while moving slowly in an upward direction. The vibrations number 200 a minute. The pulp is led on at the higher end, and the flow of the water carries the light matters down the slope, the separation being greatly assisted by the shaking movement. The residue is also sprayed with water, and the heavy matters only are carried forward by the belt over the higher end and pass into a box below, being then known as "concentrates." These may be ground for a prolonged period with mercury (old fashioned), or treated by chlorination. For cyanide treatment, concentration is unnecessary.

Chlorination Processes.— The concentrates are first calcined to remove the sulphur and arsenic, and to render the material more porous. The residue is treated in vats provided with false bottoms and with filter beds, or other suitable receptacles, having tightly fitting covers. The calcined ore, as free as possible from "slimes"— very fine material which becomes impervious when wet — is dampened with water and sifted into the vats, in order that it may lie lightly. The cover is put on and luted, but a plug in the top taken out. Chlorine gas is admitted slowly under the false bottom of the vat through a pipe for that purpose, and gradually lifts out the air. The plug is then inserted, and the chlorine allowed to act for some 30 to 40 hours, fresh supplies of the gas being added if found necessary. The vat is then ventilated. the cover removed, and the ore treated with water several times to dissolve the chloride of gold that has been formed. The solution drains through the filter bed, and passes out into the settling tank, where any sand, etc., is deposited. From the settlers it passes to the precipitating tanks, where a solution of sulphate of iron — ferrous sulphate — or other precipitant is added, and the whole thoroughly paddled or mixed by mechanical stirrers. The gold is thus precipitated as a brownish purple powder, which is allowed to settle, and the liquor is then siphoned off. Several batches of solution are thus treated, and the gold obtained is collected, washed with acids, dried, and melted in crucibles. Many modifications of the original process with special forms of plant have been introduced. In the Newberry-Vautin process air is pumped into the chlorinating vessel to increase the pressure; in the Pollok process hydraulic pressure and rotation are employed; and the Mears works under pressure of chlorine. In several of these modifications the chlorine is generated in the chlorinating vessel by means of bleaching powder, and either sulphuric acid or acid sulphate of soda. Various precipitants have also been employed. See Gold.

Pyritic Smelting.— This term is applied to a method of smelting pyritic gold ores in cupolas, with or without the addition of coke. If the ore contains above 40 per cent of sulphur no coke is necessary. On charging the ore into the cupola some of the sulphur is driven off by the heat, and part of the remainder when it reaches the twyers burns and furnishes sufficient heat to melt the regulus — a sulphide — and slag off the ferrous oxide resulting, and the quartz. A plentiful supply of air is required. The gold remains in the regulus, which also contains any copper present.

Gold Refining and Parting.— The crude bullion is dealt with according to its purity. Very

base bullion is cupelled with lead, only the silver and gold remaining on the cupel. When less impure it is melted in crucibles and nitre and borax added to oxidize and flux the copper and other metals it contains. After this treatment the bullion still contains silver as well as small quantities of other metals, to separate which the gold is "parted." This is effected by boiling the alloy in acids to dissolve out the silver, but unless a sufficient quantity of silver is present the acid will not completely dissolve it. The gold is first alloyed with the necessary quantity of silver. For nitric acid parting the alloy contains two and a half or three times as much silver as gold. When sulphuric acid is employed it contains four times as much or more. The alloy is granulated by pouring the molten metal into water, and the granulated metal is then boiled with nitric acid in glass or platinum vessels, whereby the silver is converted into silver nitrate and dissolved, the gold remaining unattacked. After drawing off the solution the residue is washed, dried, and melted down. The silver in the solution is afterward recovered by precipitating it with hydrochloric acid as chloride, which is subsequently reduced to metal. At the same time the nitric acid is recovered. Sulphuric acid is often used in place of nitric, particularly in dealing with silver containing a little gold. The granulated metal is first boiled with sulphuric acid, in iron pans, suitably provided with covers to carry off the vapors for the recovery of the acid. This converts the silver into soluble sulphate of silver. After a second treatment the residue is washed, dried, and melted down. The silver is recovered from the sulphate by treatment with ferrous sulphate or other reducing agent, or by passing the solution over metallic copper, by which it is precipitated. The precipitated silver is afterward washed and melted down. When little silver is present it may be removed by melting the gold in a crucible and bubbling chlorine gas through the molten metal by means of a clay tube passing through a hole in the cover. The silver is converted into chloride, which melts and rises to the top of the metal. The gold is not chloridized, the temperature being sufficient to completely decompose its chloride. The scum contains some gold, and this is afterward recovered. Besides removing the silver, any traces of lead, antimony, bismuth, tellurium, or other base metals which would render the metal brittle are converted into chlorides and volatilized so that the metal is left tough and malleable. The process is often employed to toughen brittle gold. The employment of bichloride of mercury by gold-beaters to toughen the gold used for that purpose produces a similar effect, the chloride of mercury giving up half its chlorine for the purpose, and being volatilized as calomel. Platinum is separated from gold by alloying with so much silver as to reduce the platinum below 9 per cent. The alloy is then parted by nitric acid, when the platinum dissolves out with the silver. Osm-iridium, a hard alloy, which often occurs with alluvial gold, is removed from the metal before parting by allowing it to subside to the bottom of the pot after addition of silver. This it does owing to its being heavier than gold.

The Cyanide Process.— As defined in the letters patent, this process consists in separating precious metals from ore containing base metal by subjecting the powdered ore to the action of a cyanide solution containing cyanogen to one thousand parts of water. By treating the ore with this dilute cyanide solution, the gold or silver is obtained in the solution, while any base metals in the ore are left undissolved. From this latter solution the gold is precipitated by its disposition on filiform zinc. Chemically, the process is based on this reaction in which a double cyanide of gold and potassium is formed: $2An + 4KCy + O + H_2O = 2K\,An\,Cy_2 + 2KHO$, or according to Feldtmann in his 'Notes on Gold Extraction': $2An + 8HCy + 3O = 2An\,H\,Cy_4 + H_2O$. Two parts of gold plus four parts of cyanide of potassium, plus oxygen from the air, plus one part of water equals two parts of double cyanide of gold and two parts of potassium hydrate. The cyanide process is especially valuable in treating tailings heretofore left on the dumps, not being collectible on the amalgamated plates as is the coarser gold. For cyanide treatment, the free milling ore-tailings should be taken directly from the battery to the cyanide works as any decomposition products vitiates the action of the cyanide.

Stages in the Cyanide Treatment.— The first process consists in passing a dilute alkaline and cyanide wash through the powdered ore, saturating the latter. This first alkaline wash may be 3 parts cyanide of potassium (KCy) to 2,000 parts water and should contain 4 ounces of caustic soda per ton of the wash; after this, the saturated ore should leach for say three hours. The next process consists in passing a much stronger cyanide solution over the washed ore. This second solution should contain from one third to one half of 1 per cent cyanide of potassium (KCy), and 100 per cent water, according to the richness and nature of the tailings to be treated, and the diluted cyanide solution should not be less than one third the weight of the tailings in the vats. For this solution and its contact with the ore at least five hours should be allowed, after which the ore should remain nearly double this time in leaching and three or four for drying. It may now be assumed that much of the gold is in solution. The next process is to subject these tailings to another wash, the object being to wash out the dissolved gold. For this purpose, after the previous strong solution has been drained off, a wash of three fourths to four fifths of the weight of the ore and composed of 3 parts cyanide of potassium (KCy) to 2,000 parts water is used. The ore treated by this weak solution should remain for draining off six or eight hours; finally, a water wash should be applied, the quantity of water used being 7 per cent or more of the weight of this ore; this should be leached off for several hours.

The Precipitation.— The cyanide solutions containing gold, as they flow from the leaching vats, are passed through one or more precipitating boxes containing zinc shavings upon which the gold is precipitated. The quantity of gold cyanide solution flowing through each box containing the zinc shavings must be carefully regulated; which may be ascertained by assaying the solution at intervals. The zinc shavings having reconverted the gold into metallic forms, the next process is the collection of the metal. Care should be taken that no iron or metal other than zinc be exposed to the solutions in the boxes. The tray holding the zinc shavings is

lifted out from the last compartment and moved up and down so that the fine particles of slime and zinc should fall through the sieve and settle in the bottom of the box.

The zinc shavings are next taken out of the tray and rubbed in the water to remove all the gold possible adhering to them. The tray is turned over and brushed down so as to remove any gold adhering to it. After this the solution of water in the zinc boxes is pumped into settling tanks, where it is allowed to stand for two weeks; thus giving the extremely fine particles of gold held in the suspension time to settle. Great care should be taken in pumping not to disturb the gold-zinc slimes at the bottom of the box. The gold-zinc slimes are now shoveled into enameled iron buckets and discharged through a 900-inch sieve, and washed and rubbed into the gold clean-up tank. The water having settled in the latter tank is siphoned off, and the precipitate (gold-shines) is drained off through plug holes and deposited upon a calico or linen filter, or into a filter press. When sufficiently dry, the gold-shines are on an iron plate or in iron pots and are ready for roasting and smelting, the object being to oxidize the greatest portion of the zinc which in the form of small chips and shavings, has fallen through the zinc box trays. Having placed the dried precipitate in a plumbago crucible and covered the same with usual fluxes — bi-carbonate of soda, borax, and sand in the proportion of 50 per cent bicarb., 25 per cent borax and 16 per cent sand to 100 per cent by weight of precipitate — the entire mass is melted, poured into molds, and after settling and cooling may be turned out, and freed from the slag by hammering off the latter. Thus the pure gold bullion is obtained. In the treatment of ore-tailings by the cyanide process, the amount of cyanide necessary varies from three fourths of a pound to one and one fourth pounds per ton of tailings, and the cost of this amount is insignificant.

Estimates on the cost of cyanide plants can be only approximately stated. The following figures may, however, be considered within limits:

To treat 3,000 tons of ore per month	$25,000
To treat 5,000 tons of ore per month	37,500
To treat 7,000 tons of ore per month	50,000
To treat 16,000 tons of ore per month	90,000

Gold Mining, Dry Placer Method.— The latest invention of Thomas A. Edison has perfected a device for separating the gold from the placer gravel without the use of water. It has been impossible to work these fields because the water needed for the proper operation of the hydraulic system was not at hand.

Mr. Edison employs an air blast to separate the gold from the gravel and other impurities. Like most of his inventions this one is simple.

The old placer system, with the hydraulic stream, got out 75 per cent of the gold, but with Mr. Edison's system of dry washing, it is said, 98 per cent of the gold is saved. When water is obtainable the new system cannot compete with the hydraulic, because the stream washes out gold at the cost of 3 cents a ton while the new plan costs 8 cents.

After the gravel has been excavated by steam shovels it is conveyed to the mill, where it passes through, or over, a series of screens, thereby being separated into particles of uniform size. Each separator is so constructed as to handle gravel of a certain size, and the gravel is distributed automatically to a machine and thence passes to a hopper, situated on top of the separator. Here a roller regulates the feed of the gravel through a narrow slit in the top of the machine, and the gravel falls to the bottom.

Back of this slot and under it there is a rotary blower, which directs a powerful blast against the falling gravel, which falls down almost as a thin screen. The heaviest metal falls directly to the bottom of the separator, but the blast throws the lighter gravel, black sand and iron into a separate compartment, leaving the gold alone and so nearly undefiled that any impurities may be removed by simple processes.

Gold of Pleasure, an annual cruciferous plant (*Camelina sativa*), with abundant yellow flowers, called "cameline" by the French and "dotter" in Germany. It is a weed in lint-fields, but is also cultivated in parts of Europe for the sake of the oil in its seeds. Its seeds and oil-cake are, however, inferior to those of flax, rape or colza. The stems are used for thatch, and made into brooms; and their fibres are sometimes woven into very coarse cloth and packing-paper. The seeds are used for emollient poultices. *C. dentata* is similar, but is not cultivated.

Gold Reserve (United States Treasury). All banking institutions must retain, to pay to depositors or note-holders who may wish to recall their money or claim the fulfilment of the promises on the notes, a stock of coin of a kind satisfactory to the claimants. The amount of this "reserve" needed in quiet times is ascertainable by experience, and is but a small part of the total deposits or issues, as only a small and calculable percentage of customers will wish their money at one time; in times of panic no estimate can be made. The United States formerly directed the Treasury Department to hold a reserve of $100,000,000 in gold, to protect its credit; but the silver panic of 1894 showed that no such arbitrary figure is of any value. When no fear of government solvency was entertained, scarcely any was needed; when the enormous silver purchases had come to threaten a breakdown of national credit by its coming on the market, the sudden rush for gold brought the reserve within three days of extinction, and only the sales of bonds and the knowledge that the policy would be pursued prevented suspension of specie payments. The abandonment of the silver policy has made another "run" less likely; but the government prefers to retain a larger reserve than the former limit. The nominal reserve (see article below) is now $150,000,000; and the recent good business years and excess of exports had brought

the actual cash on hand 1 Nov. 1902 up to $350,421,878.30.

Gold Standard and Gold Production. The metal gold is the only substance of which the earth is composed that is freely accepted in return for all services and in exchange for all other kinds of property by every race in the world. In other words, it is the world's standard of value; the one commodity the market for which cannot be glutted; the one substance that is everywhere accepted not only without compulsion and without limit as to quantity, but that is also the particular object of universal desire. As a mineral it has a history that is probably almost as old as the human race that has fought for its possession with so much avidity. No less than 1,400 years before the dawn of the Christian era, the Greeks were using it as an object of ornamentation, and yet even they were not the originators of the practice. They had borrowed the custom of wearing gold to make the person more attractive from the Egyptians, a people that had decked its women in gold more than 1,000 years before the Greeks had dreamed of utilizing it in this manner. It was, of course, the use of gold as an ornament that first suggested its subsequent use as money, and that finally made it the standard upon which the coinage of the world is based.

Among the many things for which the 19th century will always be memorable not the least important will be the fact that it was during this period that the single gold standard was adopted by practically all the civilized nations of the earth. Beginning with a monetary system that, in a broad sense, may be described as the double standard of silver and gold, the nations of the ancient world maintained this method until sometime in the Middle Age. From about the beginning of the seventh century, however, and until sometime in the 13th century, the single silver standard of coinage prevailed, and, when the double standard was then reintroduced, it remained in vogue until the 19th century, when the progressive financiers began to appreciate the need of a better system.

England was the nation that led the way in the work of exchanging the double standard of silver and gold for the single gold standard, but, while this was done in 1816, other countries were slow to follow in her footsteps. It was not until 1854, therefore, that the double standard was superseded by the single standard in Portugal, but Germany followed in 1871; the United States, in 1873; the Scandinavian States, in 1874; Holland, in 1875; France and the Latin Union, in 1876; Austria-Hungary, in 1892; British India, in 1893; Japan, in 1898, and Russia, in 1899. The gold standard also prevails in Roumania, Servia, Turkey, and Egypt, but, while all the South and Central American countries, with the exception of Bolivia, Colombia, Guatemala, Honduras, Nicaragua, Salvador, and Paraguay have adopted it, most of them are almost hopelessly entangled in a mass of irredeemable paper. It may thus be seen that, among all the nations of importance, China and Mexico alone failed to adopt the single gold standard during the 19th century, while the latter is now (1905) taking the necessary steps to remedy her financial ills by the adoption of such a standard.

It was not alone for this reason that the 19th century was closely identified with the history of gold, however, for it is this period that will always be noted for having been the occasion of two great events in the world's record; the greatest discovery of gold and the greatest production of gold. According to the statistics prepared by the director of the mint, the world's production of gold during the first half of the 19th century was $787,463,000, while, for the second half, it was $6,909,040,000. At the beginning of the century the most important gold-producing countries were Mexico, Colombia, Peru, Brazil, and Buenos Ayres, in the western hemisphere, and Russia and Hungary in the eastern hemisphere. With the exception of small quantities that were obtained in Africa and from the East Indies there was practically no other places where the metal could be found. During the period from 1801 to 1810, the average annual yield of these countries was not in excess of $12,000,000, and fully two-thirds of this amount came from the American mines. Owing to the revolutionary disturbances that broke out in Mexico and throughout South and Central America during the period between 1810 and 1824, the output of gold, as well as that of silver, was greatly reduced. At this time the world's production of gold declined until it reached the comparatively low average of about $7,600,000 per annum, an amount which, in the opinion of William Jacob, one of the best authorities of that period, was insufficient to supply the quantity used in the arts and to make good the loss by accidents, such as by abrasion, shipwreck, etc. As the restoration of peace was quite generally effected about this time, however, disaster was avoided ,for the increase in the production of gold, which began at once, steadily continued. Even the average output of Russia commenced to show some remarkable gains, her production between 1837 and 1848, averaging more than $12,500,000 per annum, which was in excess of the production of the entire world at the beginning of the century. The following table gives the details of the world's production during the first half of the century as computed by the director of the mint:

PERIOD.	Annual average	Total for period
1801-1810	$11,815,000	$118,152,000
1811-1820	7,606,000	76,063,000
1821-1830	9,448,000	94,479,000
1831-1840	13,484,000	134,841,000
1841-1850	36,393,000	363,928,000
Half-century	$15,749,200	$787,463,000

The era of gold discovery dates from 1848, when James Wilson Marshall, on 19 January, discovered a small lump of gold in the tail-race of Sutter's saw-mill, in El Dorado County, Cal. Naturally such a discovery led to a search, not only of the bed of the stream but in the adjoining ground, and, in both places, rich deposits of the precious metal were found. The story of the rush that followed this find of new gold fields is a familiar tale to readers of American history. The news spread like wildfire through California, down the Pacific coast to South America, and finally east to the Atlantic States, and so to Europe. In response to these tid-

ings gold hunters flocked from every inhabitable portion of the globe, with the result that the gold production of California alone amounted to $36,000,000, or a sum equal to that which the annual average of the entire world had attained during the preceding decade. A year later it had reached the sum of $56,000,000, and it was in that year that a similar discovery of placer gold was made in New South Wales, which was followed shortly by a still more important find in the colony of Victoria. New mines were also discovered in Russia during this period, and as all these discoveries were attended by great public excitement and heavy immigration the new mines were so well worked that the production of Australia and New Zealand soon aggregated $65,000,000, while that of Russia alone was in excess of $25,000,000.

The finding of the Comstock lode in Nevada was the next great discovery of the precious metal. This fissure vein, which was fully four miles long, was in rock of the Tertiary Age, and was situated at the base of Mt. Davidson, in the Virginia range, an offshoot of the Sierra Nevada. In the central part of the fissure its width is about 3,000 feet, while the gangue, or veinstone, is quartz, not uniformly distributed in the fissure, but coagulated in large bodies commonly known as "bonanzas." Apparently the metal had been deposited in this place in solution, while some idea of the tremendous magnitude of the deposit may be obtained from the fact that, since 1861, the year when it was first scientifically worked, the Comstock lode has yielded more than $350,000,000 of bullion. At the value ratio of 1 to 16.40 per cent. of the bullion produced was gold, while 60 per cent. was silver. As the richest ore bodies of the lode had been exhausted during the seventies, the annual yield gradually declined until, in 1882, it was less than $1,500,000, but as attention was then turned to the working of such lower-grade ores as had previously been neglected, the annual production gradually increased until it had again attained a figure of several millions.

It was about this time (1884) that there was discovered in the Witwatersrand of the Transvaal a deposit of gold that was destined to surpass in magnitude, not the Comstock alone, but every other find of the precious metal that the world had ever seen. Here the country rock is a bed of sandstone, interlaminated with deposits of conglomerate, known to the Dutch as "banket." It is this conglomerate that carries the gold, the average being 10 pennyweights per ton of material. Borings to the depth of 3,500 feet, however, have found the proportion of gold in this reef undiminished, while the outcroppings of the reef have been traced for a distance of 40 miles. The working of these mines gave the Transvaal a gold production of $78,070,761, in 1898. Then came the interruptions due to the war with Great Britain, in 1899, and this, with other disturbances, made a full resumption of the work impossible prior to about 1904, although it is believed that the output of the Rand willl yet equal the sum of $100,000,000.

The most surprising discovery of modern times, however, was the finding of the gold placers of the Klondike, in 1894. As the ground underneath which this gold is found is perpetually frozen, it is quite evident that these deposits must have been laid down at some age when the climate of that region was much warmer than it is at present. To procure this gold to-day, however, it is necessary to sink a shaft through the frozen ground by the use of hot boulders, after which the drift is run by building a fire against the face of the ground, the gravel which is then thrown out being left until summer, when it will thaw sufficiently to permit of washing and panning. It has been estimated that all the gravel which two men are able to throw out during the eight months of winter, can be washed by the same men in two months of the summer. In spite of the difficulties of mining and the cost of transportation the output of the Klondike region steadily increased until 1900, when it was estimated at more than $20,000,000. Since that time there has been a slight falling off in the product, which, in 1904, was figured as somewhat more than $16,000,000. Similar placer mines have also been discovered in the Cape Nome region of Alaska, and, in 1904, their output amounted to more than $9,000,000.

At the present time, however, the most important gold-bearing district within the borders of the United States is that at Cripple Creek, Col. This ore is a telluride, known to mineralogists as calaverite. The country rock is altered andesite, granite, or phonolite, containing thinly disseminated iron pyrites and tellurium minerals. The tellurium, at or near the surface, is oxidized, and the gold, when it is visible, exists as an ochre-like powder known as "mustard gold." The tellurium, through a process of roasting, is oxidized, and the gold thus set free in the metallic state is easily soluble by cyanide or chlorination. The estimated yield of the Cripple Creek district in 1904 was $24,000,000. The increase in the gold production of Australia during recent years has also been a remarkable factor in extending the world's output. During 1900, new workings were established in West Australia, and these, with the product of the older mines, produce an amount of gold, which, in 1904, was approximated at nearly $88,000,000.

The statistics showing the world's production of gold during the second half of the century, as compiled by the director of the mint, are as follows:

Period.	Annual average.	Total of period.
1851-1855	$132,513,000	$662,566,000
1856-1860	134,083,000	670,415,000
1861-1865	122,989,000	614,944,000
1866-1870	129,614,000	648,071,000
1871-1875	115,577,000	577,883,000
1876-1880	114,586,000	572,391,000
1881-1885	99,116,000	495,582,000
1886-1890	112,895,000	564,474,000
1891-1895	162,947,000	814,736,000
1896-1900	257,596,000	1,287,978,000
Half-century	$138,181,000	$6,909,040,000

The production of the world by single years from 1901 to 1904, inclusive, was:

Year.	Production.
1901	$263,374,800
1902	295,889,600
1903	325,527,200
1904	346,892,200
Total for 4 years	$1,231,683,800

The world's production of gold in 1904, according to the same authority, was divided as follows:

Counties.	Value.
Australia	$87,767,300
Africa	85,913,900
United States	80,464,700
Russia	24,803,200
Canada	16,400,000
Mexico	12,605,300
India	11,485,500
China	4,500,000
All others	22,942,300
Total	$346,892,200

The production of the United States and its territories during 1904 was divided as follows:

State, etc.	Value.
Colorado	$24,395,800
California	18,994,800
Alaska	9,160,500
South Dakota	7,024,600
Montana	5,097,800
Nevada	4,307,800
Utah	4,215,000
Arizona	3,343,900
Idaho	1,503,700
Oregon	1,309,900
All others	1,110,900
Total	$80,464,700

In concluding this review of the gold situation it may be interesting to note the manner in which new supplies of gold operate on prices. From a commercial point of view, gold stands for purchasing power, and yet people do not mark up the prices of their goods merely because some new gold mine has been discovered, but the fact that some men have $2 in their pocket where they had only $1 before creates a greater demand for goods, and it is to this increased demand that the advance in prices is due. It was in this way that the new supplies of gold acted when they brought about an increase in both prices and wages during the 20 years succeeding the discovery of the precious metal in California. This result was not brought about because the community was richer for the privilege of having two dollars instead of one with which to transact a given amount of business, but because, as Professor Cairnes shows, the distributions of the earnings of society was shifted by giving the advantage to wage-earners over rentiers and others having a fixed income. The former had more steady employment and better wages than before, while the latter were compelled to pay higher prices for the goods which they consumed without experiencing a corresponding increase in their income.

Gold Standard Bill, a short name for the act of 14 March 1900, «To define and Fix the Standard of Value, to Maintain the Parity of All Forms of Money Issued or Coined by the United States, to Refund the Public Debt, and for Other Purposes.» It provides that the dollar of 25.8 grains of gold, .9 fine, shall be the standard unit of value, and all forms of money issued or coined by the United States shall be maintained at a parity of value with this standard, and it shall be the duty of the secretary of the treasury to maintain such parity. All United States notes and treasury notes issued under the act of 14 July 1890 shall be redeemed in gold coin as above, and to secure this the secretary of the treasury is directed to set aside a reserve of $150,000,000 in gold coin and bullion, to be used for such redemption purposes only. If this reserve falls below $100,000,000 despite certain assigned methods of replenishing it, the secretary shall pledge the credit of the United States by issuing bonds at not exceeding 3 per cent interest, payable quarterly, exempt from all taxation. This is not to interfere with the legal-tender quality of silver money already in circulation. As fast as silver dollars are coined under previous acts, an equivalent amount of treasury notes shall be retired, and silver certificates issued instead. The coinage of subsidiary silver coins, and the recoinage of such as are out of circulation, is provided for. This act is not to prevent international bimetallism if it is found possible to secure a stable relation between gold and silver.

Goldau, gŏl'dow, a valley in Switzerland, in the canton of Schwyz, between Mount Rigi and the Rossberg. On 2 Sept. 1806 a landslide from Mount Rossberg destroyed the village of Goldau and three other villages situated in the valley, killing about 450 persons. A little village built in the valley, near the mines, is called Goldau. It has a population of about 490.

Goldchain, or **Golden Moss.** See STONECROP.

Gol'den, Colo., city, county-seat of Jefferson County; on Clear Creek, and on the Union P., the Denver, L. & G., and the Denver & G. R.R.'s; about 15 miles west of Denver. In the vicinity are deposits of coal and brick clay. The chief industries are smelting, the manufacturing of brick and pottery, and flour milling. A State Industrial School and a School of Mines are located here. Pop. 2,203.

Golden Age, among the Greeks and Romans was the reign of Saturn, whose blessings are described by Virgil in his eclogue addressed to Pollio. The Latin poet was borrowing from the Greek Hesiod who depicted the Golden Age as the patriarchal era of Saturn or Cronos. This was followed by the Silver Age of voluptuousness under Jupiter. Then came the Brazen or warlike age under Neptune. To this succeeded the Heroic Age under Mars, the Iron or utilitarian Age under Pluto, god of riches. The Golden Age in England was the reign of Elizabeth (1558–1603); in France under Louis XIV. The Golden Age of German literature included the period between Klopstock and Goethe (1750–1850). The Golden Age of Italian art was the famous 'Cinque Cento' extending from the life of Leonardo da Vinci (d. 1520) to Michelangelo (d. 1576).

Golden Beetle, one of the richly gilded beetles of the family *Chrysomelidæ* (q.v.).

Golden Bible, the Book of Mormon, which Joseph Smith, Jr., professed to have found in 1823. He declared that an angel appeared to him, and led him to the discovery. He was not, however, allowed to take up the gold plates on which the book was written until four years later. Joseph Smith was at first unable to read the «reformed Egyptian» characters in which the revelation was written until, in the same box with the plates, he discovered an instrument called Urim and Thummin, by the aid of which he translated the Golden Bible into English and published it in 1830, with the certificate of 11

men testifying that they had seen the plates of gold.

Golden Bull, a name given to several state documents; the principal ones are as follows:

1. Of Hungary, 1222, wrung from King Andrew II. by his nobles, just as Magna Charta was extorted from John of England. Andrew II. of Hungary, surnamed "Hierosolymitanus," was a feeble, self-willed, worthless king, like John of England. Its terms were:

The nobles and the Church were to be exempt from taxes.

The daughter of a noble without male heir shall inherit one fourth of his property.

No noble shall be obliged to follow the king in any foreign war.

The palatine (that is, mayor of the palace), shall be the supreme judge.

No foreigner to hold office or dignity without consent of the council of the realm.

The king shall not grant counties or offices of any kind in perpetuity.

If the king violates any of the laws in this bull, it shall not be treason to levy war on him.

This bull was so called because the attached seal was enclosed in a golden case or box. It is rather remarkable that one of the very first countries in Europe to effect the liberty of subjects should have been one of the last-born nations, the Huns of Hungary.

2. 'Bulla Aurea of the Empire,' 1356, published by Kaiser Karl IV. at the Diet of Nuremberg, and held the Magna Charta of Germany. It prevented a repetition of the contests which had hitherto arisen whenever a vacancy in the throne occurred; and regulated the functions, number and privileges of the electors. Called "golden" because the seal attached to the parchment was of gold instead of lead, or else that it was enclosed in a golden case.

It limited the number of electors to seven (three prelates and four lay princes). The prelates were the three Archbishops of Maine, Cologne, and Treves; the lay princes were the King of Bohemia, the Duke of Saxony, the Margraf of Brandenburg, and the Pfaizgraf of the Rhine. Their persons were declared sacred. Every question was to be decided by majority and without appeal.

Golden Calf, an idolatrous image, doubtless of Egyptian suggestion and symbolism, cast by Aaron from the earrings of the people, while the Israelites were encamped at the foot of Sinai, and Moses was absent on the Mount.

Golden Circle, Knights of the. See KNIGHTS OF THE GOLDEN CIRCLE.

Golden Cross, United Order of the. See UNITED ORDER OF THE GOLDEN CROSS.

Golden-crowned Sparrow, Thrush, etc., birds so named for some conspicuous yellow marking on the top of the head. The sparrow (*Zonotrichia coronata*) is a near relative of the white-crowned, or Peabody bird (q.v.), and is seen in the United States only in the spring and fall; it sings brilliantly in its Arctic and Alaskan breeding-home. The golden-crowned "thrush" is a warbler, bettter known as "oven-bird" (q.v.). The "wren" or "gold-crest" is a kinglet (q.v.).

Golden or War Eagle. See EAGLE.

Golden Eagle, Oriole, Plover, Shiner, Warbler. See EAGLE; ORIOLE; PLOVER; etc.

Golden-eye, or **Whistle-wing,** a duck (*Clangula clangula*) which breeds numerously in all northern regions, where its nest is made in holes in trees, or (in Lapland) in suitable boxes placed in trees. The American birds form a geographical race called *Americana*. During cold weather they appear in the United States and the middle districts of Europe, traveling about in small, watchful parties which escape swiftly on the least alarm, and arouse all other ducks within sound of the loud noise made by their wings. An European name is "garrot." The general color of the drake is white beneath, with head and sides of neck rich green, back and tail grayish-black, and the bill bluish-black; it has a round white spot before each eye, the iris of which is golden yellow, and two white bands on the wing; length about 19 inches. The female is ashy, with rufous head. In the Rocky Mountains and northward occurs a second somewhat larger species, Barrow's golden-eye (*C. islandica*), which differs prominently in the greater extent of the loral spot.

Golden-eyed Fly, a lace-winged fly (q.v.).

Golden Fleece. See ARGONAUTS.

Golden Fleece, Capture of the ("Argonautica"), an epic poem in four cantos, by Apollonius of Rhodes (235 B.C.), a contemporary of Ptolemy Philadelphus. Apollonius found all the elements of his poem in the legendary traditions of the Greeks; the expedition of the Argonauts being, next to the siege of Troy, the most famous event of the heroic ages. The third canto describes the conquest of the Golden Fleece, and the beginning of Medea's love for Jason, the development of which forms the finest portion of the poem. The Argonauts go through the most surprising adventures, and encounter perils of every description, before they are able to reach the port from which they started. These various events have allowed the poet to introduce brilliant mythological pictures such as his account of the Garden of the Hesperides. The work has been frequently translated, and is admittedly the masterpiece of Alexandrian literature. The 'Argonautica' of Valerius Flaccus is an imitation of that of Apollonius, regarded by most modern scholars as without originality or invention.

Golden Fleece, Order of, a celebrated order of knighthood in Austria and Spain, founded by Philip the Good, duke of Burgundy and the Netherlands, at Bruges, 10 Jan. 1429, on the occasion of his marriage with Isabella, daughter of King John I. of Portugal. The order was instituted for the glory of the saints and the protection of the Church, and the fleece was probably assumed for its emblem as much from being the material of the staple manufacture of the Low Countries as from its connection with heroic times. The number of the knights was 31, and they themselves filled up vacancies by vote. This continued till 1559, when Philip II. of Spain held the last (the 23d) chapter of the order in the cathedral of Ghent; and subsequently Philip obtained from Gregory XIII. permission to nominate the knights himself. After the death of the last Hapsburg king of Spain in 1700, the Emperor Charles VI. laid claim to the sole headship of the order in virtue of his possession of the Netherlands, and, taking with him the archives of the order, cele-

brated its inauguration with great magnificence at Vienna in 1713. Philip V. of Spain contested the claim of Charles; and the dispute, several times renewed, was at last tacitly adjusted by the introduction of the order in both countries. The insignia are a golden fleece (a sheepskin with the head and feet attached) hanging from a gold and blue enameled flint-stone emitting flames, and borne in its turn by a ray of fire. On the enameled obverse is inscribed *Pretium laborum non vile*. The decoration was originally suspended from a chain of alternate flints and rays, for which Charles V. allowed a red ribbon to be substituted, and the chain is now worn only by the grand-master. The Spanish decoration differs slightly from the Austrian. The costume consists of a long robe of deep red velvet, lined with white taffetas, and a long mantle of purple velvet lined with white satin, and richly trimmed with embroidery containing fire-stones and steels emitting flames and sparks. On the hem, which is of white satin, is embroidered in gold, *Je l'ay empris* ("I have captured it"). There is also a cap of purple velvet embroidered in gold, with a hood, and the shoes and stockings are red. See Reiffenberg, 'Histoire de l'Ordre de Toison d'Or' (1830); and Zoller, 'Der Orden vom Goldenen Vlies' (1879).

Golden Gate, a channel at the entrance to San Francisco Bay, between the peninsula upon which is located San Francisco and the one upon which Sausalito stands. The average width is two miles, and the depth is sufficient for ocean steamers. It is guarded by Forts Pointe and Mason, both on the south shore, and by a fort on Alcatraz Island. The name was given to this channel by Drake, about 1578.

Golden Hind, The, one of the two vessels in Sir Humphrey Gilbert's colonizing expedition of 1583. Gilbert's own vessel was the Squirrel, and he went down with it in a storm. The Golden Hind, Capt. Edward Hales, returned to England with the news.

Golden Horn, the harbor of Constantinople, an inlet of the Bosporus; so called from its shape and beauty. See CONSTANTINOPLE.

Golden House of Nero, a palace which Nero erected for himself at Rome after the disastrous fire of 64 A.D. This palace stretched from the Palatine across the level area on which the Flavian amphitheatre was afterward built to the foot of the Esquiline. According to Tacitus, whose virulence is often unjust, Italy and the provinces were plundered to gratify the emperor's love of magnificence in the erection of this structure. Gold and precious stones blazed on its walls; the grounds around it were variegated with meadows, lakes, and shady woods, and it was considered one of the wonders of the Roman empire.

Golden Mole, or **Cape Mole**, a South African insectivore with fur showing golden iridescence. It has the habits of a mole, no external ears or tail, and the eyes covered with skin; but a greater structural resemblance to the potamogales (q.v.). Five species constitute the family *Chrysochloridæ*, differing from moles (q.v.) most markedly in the fact that the fore-feet are adapted for digging by the development of the middle toe into a powerful tool, and by a hollowing inward of the chest. The best known species is *Chrysochloris trevelyani*, about six inches long.

Golden Oriole, commonly known as the Baltimore oriole, an American bird (*Icterus galbula*), closely allied to the *Ploceidæ*, weaving birds of Asia. Its nest is skilfully constructed so as to hang in the form of a long slender pouch from the extremity of a bough. Its plumage is brilliantly contrasted in color, and as black and yellow were the armorial colors of Lord Baltimore it was named in early colonial days after that nobleman. It is found in the hot months as far north as the coast of New Brunswick, and westward from the Saskatchewan River to Texas and northern Louisiana. In winter it migrates to Panama and the West Indian Islands. It is a powerful and delightful songster. Its eggs are from 4 to 6 in number and hatch in 14 days. The golden oriole is the farmer's friend and destroys many insect pests which are destructive to vegetation.

Golden-rod (*Solidago*), a genus of plants belonging to the *Compositæ*, containing about 85 species, most of them natives of North America, where their brilliant yellow flowers are very conspicuous in the autumnal months, especially in Canada and the northeastern United States. Two or three species are found in Europe, and a few in South America and Mexico. They are perennial, chiefly herbaceous, with simple undivided leaves, and bear numerous small flowers, disposed in spikes or panicles. Among the marked forms of inflorescence are the pyramidal panicle of numerous, one-sided, scorpioid racemes, well illustrated by the *S. canadensis* and *S. rugosa;* the almost level cyme of the *S. rigida;* and the dense thyrsus-like cluster of the *S. speciosa.* The florets of the ray are about five in number, and yellow, the *S. bicolor* excepted, which has whitish rays. The dried leaves of the sweet-scented or anise-scented golden-rod (*S. odora*) have been used as a substitute for tea. This plant yields an aromatic oil with tonic properties. In Europe the different species are cultivated in gardens for ornament; one, the Aaron's rod (*S. virgaurea*), is common in Great Britain. The Alpine golden-rod is found on the summits of mountains in Maine, New Hampshire, and northern New York, and also in Europe. The sea-side or salt-marsh golden-rod (*S. sempervirens*) is an especially showy species; and the "yellow-weed" (*S. canadensis*) sometimes attains a height of eight feet. Some species found in New Zealand and St. Helena attain to the dimensions of trees.

Golden Rose, a rose of gold, or gilded, blessed by the Pope on the fourth Sunday of Lent and sent to some sovereign or other person who is known for his or her loyalty to the Holy See. It is sometimes sent to noted churches or sanctuaries.

Golden Rule, the rule laid down by Jesus in the Sermon on the Mount, and stated by him to be the law and the prophets — that is, a summary of their teaching: "Therefore all things whatsoever ye would that men should do to you, do ye even so to them" (Matt. vii. 12). This rule had already been "examined and adopted as a standard of ethics by westerns like Socrates and easterns like Theng-tsen, the disciple and friend of Confucius, some centuries before the birth of Christ."

Golden Seal, Orange-root, Yellow Puccoon, or Yellow Indian Paint, a ranunculaceous perennial plant (*Hydrastis canadensis*) of wooded regions throughout the eastern United States, which sends up in early spring a hairy stem about a foot high, with large, deeply lobed leaves and a single greenish-white flower, followed by a head of crimson berries which resemble a raspberry. The root-stock is gathered by country people, especially in the South, for the sake of its thick orange-yellow bark from which a drastic and tonic medicine is made.

Golden State, California, so named on account of its gold deposits.

Golden Spur, Order of the, a papal order of knighthood, whose foundation has a legendary origin in Constantine the Great, or Pope Sylvester. Its institution can be traced historically to Pope Paul IV., 1559. The title of the members is "Count Hospitalers of the Lateran." The right of bestowing the order is vested in other prelates and kings beside the Pope. When it languished, Gregory XVI. revived it in 1841. It is intended to be bestowed as a recognition of conspicuous merit in personal character, science and art, and for services done to humanity and the Holy See. The badge is a gold Maltese cross with white enameled surface, to which a pendant spur is attached. On one face of the cross is a bust of Sylvester, with the inscription, *Sanctus Silvester Pont. Max.* (St. Sylvester, Pope). On the reverse is engraved "MDCCCXLI. Gregorious XVI. restituit" (Gregory XVI. restored it in 1841). The order has three grades; the ribbon is red with black stripes.

Golden Wasp, or **Gold Wasp,** a cuckoo-fly (q.v.)

Golden Wedding. See DIAMOND WEDDING.

Golden-winged Woodpecker. See WOODPECKER.

Goldfinch. (1) The familiar North American black-winged "yellowbirds" or "wild canaries" of the genus *Spinus,* the best known of which is the eastern thistle-bird or lettuce-bird (*S. tristis*), whose wave-like flight across the fields, each male singing sweetly in its course, forms one of the most pleasing incidents of a rural stroll. These little finches are bright golden-yellow, with the cap, wings, and tail black in the adult male; while the female and immature young are gray-brown and yellowish; and in autumn the male discards his conspicuous dress and assumes the plain attire of his mate. At this season they collect in flocks and remain together during the winter, seeking the seeds of the meadow-grasses and roadside weeds, especially thistles, and often coming near the house and barn. Their summer food includes more soft material, and they gather many caterpillars for their young. The goldfinch is one of the latest birds to make its nest, delaying until midsummer to fabricate the soft cup of hempen and downy materials which is lodged usually in some crotch of a village shade-tree, and contains half a dozen spotless bluish eggs. Several other species dwell in the western United States and southward. (2) The small European finch (*Carduelis carduelis*) to which the name first belonged, and whose habits are much the same as those above described, but which is more varied in plumage. The bill is horn-color, the tip black and the base encircled with crimson; nape of neck white; top of head, shoulder of wing and a part of the quills, black; remainder of wing dull yellow; back and rump dusky brown; under surface dull white. Its nest is neatly built of moss, twigs, roots, etc., lined with wool, is situated in bushes, hedges, or apple-trees, and the eggs are spotted with purple and brown. This finch is one of the sweetest singers of Europe, a favorite cage-bird, and the one most often taught pretty tricks; it is the most useful decoy in bird-catching. Examples are to be found in bird-stores all over the world; and in the neighborhood of New York many have escaped and are living wild in the parks and environs.

Goldfish, a carp (*Carassius auratus*), highly cultivated long ago in China as a domestic fish for the sake of its rich red-gold color, developed out of an originally much duller hue. It was introduced into England in 1728, and has spread over all of Europe and is naturalized in many waters of the United States as well as everywhere kept in household aquaria. The young are dark-colored, assuming the golden hue later in life, and sometimes losing it in old age, when the fish becomes silvery. The "silver fish" is a mere variety, as are the so-called "telescope fish" with large protruding eyes and the Japanese "butterfly fish," in which anal and caudal fins become more or less markedly double. All of these varieties thrive well in confinement when furnished with favorable conditions in the aquarium (q.v.), but are liable to fungus diseases of the skin. Diseased fish will infect all in an aquarium, and the aquarium itself, so that in the case of an inexpensive glass globe it is better to throw the receptacle away; a large aquarium should be emptied and thoroughly treated with some fungicide (q.v.) before new and healthy fish are installed. These fish are bred for sale by some fish culturists in various parts of the United States, who must exercise care or their stock will revert toward the original unadorned type of the species.

Golding, Arthur, English writer and translator: b. probably at London about 1536; d. about 1605. He finished the translation of Philippe de Mornay's treatise 'Sur la Vérité du Christianisme' which was begun by Sir Philip Sidney and entrusted to his care, publishing it under the title 'A Woorke Concerning the Trewenesse of the Christian Religion, etc.' (1589). Beside making translations of the works of Calvin and Beza, he also translated the first four books of Ovid's 'Metamorphoses' (1567).

Goldmark, Karl, Austrian composer: b. Keszthely, Hungary, 18 May 1830. He studied at the Vienna Conservatory. His first composition of note was the overture, 'Sakuntala' (1858); his first opera the 'Queen of Sheba' given at Vienna in 1875. His other works include: 'Merlin,' an opera performed for the first time at the Metropolitan Opera House, New York, in 1887; the overtures 'Prometheus,' 'In Spring,' and 'Penthesilea'; and the symphony 'The Country Wedding.'

Goldoni, gŏl-dō'nē, **Carlo,** Italian writer of comedies: b. Venice 1707; d. Paris 8 Jan. 1793. He early showed a taste for theatrical representations, reading every dramatic produc-

tion of which he could obtain possession, especially the works of the popular comic poet Cicognini, and, when scarcely eight sketched a comedy, which excited the wonder of his relatives. His father, a physician then practising at Chiozza, destined him for the medical profession, and took him occasionally to visit his patients. But Goldoni, dissatisfied with this study, obtained permission to study law in Venice. Soon after, however, a relative procured for him a place in the Papal College at the University of Pavia, from which he was expelled for writing an abusive satire. His father died in 1731, and from this time Goldoni lived an unsettled and wandering life, resorting to various means to make a livelihood, but usually living as the companion of strolling players in a continual scene of dissipation and intrigue until 1736, when he married and removed to Venice.

Goldoni's merits in reforming the Italian theatre cannot be mistaken. Many of his numerous pieces still retain possession of the stage in his native country, and, in translations, of the stages of foreign countries. Among the numerous editions of his works, that published at Venice in 1788 and 1794–5, in 44 volumes, is the most complete; and that published at Florence in 53 volumes in 1827 the most elegant. Translations and imitations of some of his works have been made in French, German, and English. Goldoni wrote memoirs of himself in French, in which he also composed two comedies, one of which, 'Le Bourru bienfaisant,' was produced at Fontainebleau and Paris in 1771 with great applause, and has maintained itself on the stage. See 'Memoirs of Carlo Goldoni,' translated by Black with essay by W. D. Howells (1877); Rabany, 'Le Théatre et la Vie en Italie au XVIIIème siècle' (1896).

Golds'boro, N. C., city, county-seat of Wayne County; on the Neuse River, the Atlantic & N. C., the Southern, and the Atlantic C. L. R.R.'s; about 80 miles north of Wilmington, and 50 southeast of Raleigh. It is the site of a State Normal School for colored teachers, the Eastern Insane Asylum, and the Odd Fellows' Orphanage. The chief manufactures are cotton, agricultural implements, cotton-seed oil, furniture, mattresses, and machinery. Pop. 5,880.

Goldsboro, Kinston, and Goldsboro Bridge, Engagements at. On 11 Dec. 1862, Gen. Foster, in command of the Department of North Carolina, set out from Newbern for the purpose of taking Goldsboro and breaking the railroad that connected Richmond with the railway system of the South and Southwest, and then forming a junction with the Union forces at Suffolk and Norfolk, Va. He had four brigades of infantry, a regiment of cavalry, and seven batteries and two sections of batteries, in all about 11,500 men and 40 guns. He reached Southwest Creek on the 13th, to find the bridge destroyed and his passage disputed by about 400 Confederates, with three guns. The 9th New Jersey and 85th Pennsylvania soon routed this force, capturing one gun, and Foster pushed on toward Kinston, skirmishing heavily on the way, and when within a mile of the place, 14 December, encountered a force of 2,000 men under Gen. Evans, posted between the Neuse River and a deep swamp. After a sharp fight Evans was driven across the river, firing the bridge behind him; but the fire was extinguished and 400 prisoners and six guns were taken. Evans retreated through Kinston, reformed his command two miles beyond, and withdrew toward Goldsboro. Foster followed, had a successful engagement on the 16th, at White Hall and, when nearing Goldsboro 17 December, was checked by a heavy force under Gen. G. W. Smith at Goldsboro Bridge. Foster succeeded, however, in destroying the bridge of the Weldon & Wilmington Railroad over the Neuse, also several other bridges, and about six miles of railway, and retreated somewhat rapidly to Newbern, having lost during his eight days' campaign 92 killed, 487 wounded, and 12 missing. The Confederate loss was 71 killed, 268 wounded, and 496 prisoners. The prisoners were paroled.

Union Occupation of Goldsboro.— After the capture of Wilmington by Gen. Schofield 22 Feb. 1865, his next objective point and final destination was Goldsboro, where it had been arranged that he should unite forces with Gen. Sherman, who was marching north from Savannah. Forces were assembled at Newbern, and the march began on 1 March. Kinston was occupied 14 March, after some days' sharp fighting. (See KINSTON, BATTLE OF.) The railway and bridges were repaired, and Schofield entered Goldsboro with little opposition on the 21st, and two days later Sherman joined him. Consult: 'Official Records,' Vol. XVIII.; Cox, 'The March to the Sea.'

E. A. CARMAN.

Golds'borough, Louis Malesherbes, American naval officer: b. Washington, D. C., 18 Feb. 1805; d. there 20 Feb. 1887. In 1827 he rescued the English brig Comet from a Greek pirate whose force was five times greater than his own. In 1861 he was put in command of the North Atlantic blockading squadron and the advice given by him at this time resulted in the Burnside expedition and the capture of Roanoke Island with various other positions of strategic importance in North Carolina. He became rear-admiral in 1862.

Goldschmidt, Hermann, hĕr'män gōld'-shmĭt, German painter and astronomer: b. Frankfort-on-the-Main 17 June 1802; d. Fontainebleau, France, 10 Sept. 1866. He became a pupil of Schnorr and Cornelius, and went in 1836 to settle at Paris, where he exhibited many pictures, among which may be mentioned: 'Une femme en costume algérien'; 'Le jeune Florentin'; 'La poésie'; 'La Sibylle de Cumes'; 'L'offrande à Venus'; 'Cléopatre'; 'Vue de Rome'; 'Mort de Roméo et Juliette'; etc. In 1847 he suddenly conceived the design of becoming himself an astronomer, and in this new profession he rapidly became known as one of the ablest observers of celestial phenomena. Between 1852 and 1861 he discovered 14 telescopic planets, namely, Lutetia, Pomona, Atalanta, Harmonia, Daphne, Pales, Doris, Eugenia, Europa, Alexandra, Nysa, Melete, Danaë, and Panope. In 1863 his sight began to fail, making it impossible for him to continue his observations.

Goldschmidt, Jenny Lind. See LIND, JENNY.

Goldschmidt, Meier Aaron, Danish novelist and publicist: b. Vordingborg 26 Oct. 1819;

d. Copenhagen 15 Aug. 1887. He entered journalism when quite young, edited the comic paper 'Corsaren' (1840–6), and in 1847 founded a monthly publication in which he discussed the political movement of the time, and showed himself a strong advocate of constitutional freedom. His first novel, 'A Jew,' appeared in 1845; other novels of his are: 'Homeless' (1853); 'The Heir' (1865); and 'The Raven' (1867); he also wrote a few dramas, and his autobiography (1877). His novels are most remarkable for the skill with which he pictures the life of the Jews.

Goldschmidt, Otto, English composer: b. Hamburg, Germany, 21 Aug. 1829. He was a pupil of Mendelssohn and Hauptmann at the Leipsic Conservatory, became a resident of England in 1858, was appointed a professor in the Royal Academy of Music in 1863 and its vice-principal in 1866. From 1876–85 he was first musical director of the Bach Choir. His compositions include the oratorio 'Ruth' (1867), and he also edited with Sterndale Bennett 'The Chorale Book for England.' In 1852 he married Jenny Lind (q.v.).

Goldsmith, Oliver, Irish poet and miscellaneous writer: b. Pallas, County Longford, Ireland, 10 Nov. 1728; d. London 4 April 1774. He was the son of Rev. Charles Goldsmith, a clergyman of the Established Church. He studied at Trinity College, Dublin, 1744–9, and after abortive attempts to take orders, and much reckless dissipation and imprudence, went to Edinburgh to study medicine in 1754. He remained there 18 months during which he acquired some slight knowledge of chemistry and natural history. At the end of this period he removed to Leyden. After studying at that university for about a year, he left it in February 1755 with only one clean shirt and no money in his pocket, to make the tour of Europe on foot, and actually traveled in this way through Flanders, part of France, Germany, Switzerland, and Italy. It was probably at Padua that he took a medical degree, as he remained there six months; but the death of the uncle who had hitherto repeatedly rescued him from his various straits, occurring while he was in Italy, he was again obliged to travel on foot to England, and reached London in 1756 with a few pence in his pocket. He then took lodgings in London to follow the profession of an author. He conducted a department in the 'Monthly Review'; wrote essays in the 'Public Ledger' (afterward published under the title of the 'Citizen of the World'), and a weekly pamphlet entitled the 'Bee.' In 1761 he was introduced to Dr. Johnson. In 1764 he appeared as a poet by the publication of his 'Traveler.' The celebrity which this poem procured its author was the cause of his introduction to the most eminent literary characters of the day. In 1766 appeared his well-known 'Vicar of Wakefield,' which at once secured merited applause. In 1768 his comedy of 'The Good-natured Man' was acted with but indifferent success, and he applied himself to the more certain labor of a 'Roman history,' of which he afterward published an abridgment. His poetical fame was greatly enhanced by the publication of his 'Deserted Village' in 1770, and in 1771 appeared 'The Haunch of Venison,' a poem, and a 'History of England' in four volumes. In 1773 he produced his comedy of 'She Stoops to Conquer,' which was completely successful. He did not, on this account, neglect compilation, and, besides a 'Grecian History,' he supplied the booksellers with a 'History of the Earth and Animated Nature,' composed in a manner both amusing and instructive, although the scientific acquirements of the author were not sufficient to guard against numerous errors. He was buried in the Temple Church, but a monument was erected to his memory in Westminster Abbey, with a Latin inscription by Dr. Johnson. The manners of Goldsmith were eccentric, even to absurdity; no writer of his time possessed more genuine humor, or was capable of more poignancy in marking the foibles of individuals, of which faculty his unfinished poem of 'Retaliation' furnishes a very happy specimen. As a poet, his 'Traveler' and 'Deserted Village' have given him a deserved reputation; and his 'Vicar of Wakefield' is one of the best known and most esteemed of English 18th century novels. See lives by Forster (1848), Irving (1849), Black (1879), Dobson (1888).

Goldsmith Beetle, an attractive northern dung-beetle (family *Scarabaeidæ*) measuring nearly an inch in length and shining like burnished gold. It is most abundant during May and June, flying principally at night; and, although it feeds on the foliage of various shade and fruit trees, seldom does much harm. The name is extended by entomologists to all scarabs of the sub-family *Rutelinæ*.

Goldthread, a low smooth ranunculaceous herb (*Coptis trifolia*), closely related to hellebore, whose evergreen leaves are all basal, long-petioled, and divided into three serrate broadly obovate parts; and the flowers small and white on scapes. The root consists of long, bright, yellow, bitter threads. This plant contains a white alkaloid called coptine, and a tea made of it is tonic. It grows in boggy woods throughout all northern regions. See also Coptis.

Goldtit. See Verdin.

Goletta, gō-lĕt'tä, Africa, the port of the city of Tunis, from which it is 11 miles north. In the new quarter are the bey's palace, a large dock, and an arsenal defended by a battery. Pop. about 3,000.

Golf, anciently known as Goff, Gouff, or Gowff, a game of Dutch origin, but generally identified with Scotland, where as early as 1457 the local Parliament inveighed against its abuse, and whence it has become popularized throughout the English-speaking world. The word, derived from the German *Kolbe,* in Dutch *Kolf,* signifies a club. *Kolf,* resembling golf, is a very ancient pastime in Holland and Belgium, where it is usually played on the ice.

The modern game of golf is played with clubs and balls on specially prepared courses called *links,* generally laid out on open suitable grounds. In its aristocratic development, golf is an expensive game, requiring facilities in the way of grounds and attendance and leisure which do not fall in the lines of everyone; in its practical features, however, it is democratic, and may be cultivated in every village and on every farm where spare ground is available. The simplicity of the game is attractive to beginners, but with a little experience the beginner learns how necessary are

practice, skill, and judgment to make one play well enough to be classed as a good golf player. The prime necessity is plenty of room. The ground best suited for the purpose is a reach of undulating country with a sandy soil, short, crisp turf, and plenty of holes or ruts, the latter forming the *hazards* — natural obstacles — or *bunkers* — artificial obstacles — necessary to prevent the game from being too easy. The *links* should not be less than three miles round nor more than five. Throughout it are distributed 18 artificial holes at any distance from 100 to 500 yards apart. The holes are 4½ inches in diameter, and each is surrounded with a *putting green,* a space 60 feet square and made as smooth as possible to enable the player to aim with accuracy. The other requisites are two small balls about two inches in diameter and made of gutta-percha, and a number of *clubs* adapted to the various contingencies likely to arise.

There are two styles of clubs, the wood and the iron; these consist of a long wooden handle, preferably of hickory, securely attached to a head of beech wood, or of steel as the case may be. Altogether there are 19 shapes of clubs, but six are usually sufficient for a player's needs. The different clubs are used under different circumstances; for example, the chief wooden-headed clubs are the *driver* and the *brassy,* the first being used for driving the ball a long distance, and the latter, which is shod with brass, being employed in special situations, as when the ball is in a hollow. The club called the *putter,* used when the ball is near the hole, has the head either of wood or of iron. The iron-headed clubs are the *cleek,* the *iron,* the *mashie,* and the *niblick,* all adapted for special purposes. The clubs are used for driving the balls into the holes, and the object of the player is to get his ball into all the holes successively with the fewest possible strokes. When played by two persons the game is called *singles;* when played by four persons in pairs, it is called *foursomes.* There are two chief methods of playing the game, known as *match play* and *medal play.* In the former, two players are usually pitted against each other. Attended by their *caddies,* boys carrying the bags containing the clubs, the players start from the *teeing* ground where one of them begins the match by placing his ball on a small heap of sand, or on an artificial rubber cone, known as a *tee,* and driving it as near as possible to the first hole. A good driving stroke from a tee would be 200 yards. The record, made at St. Andrews, Scotland, is 280 yards. The other player does the same with his ball, after which the player whose ball is farthest from the hole plays again. They continue thus until both balls have been holed. The player who takes the fewest strokes to do this is said to win the hole and counts one, and if both have taken the same number of strokes the hole is *halved* and neither counts. Having *holed* his ball the player takes it out, *tees* it again, and starts out for the next hole. Much of the interest of the game depends on the skilful play required to avoid the *hazards* and *bunkers* scattered over the course, or to get one's ball out when it lands in a difficult spot. In *medal play* the winner is the player who goes the round of the course in the fewest possible strokes irrespective of whether he had a majority of holes or not. Various modifications of these two modes of scoring are in use. A hole match may be won before the round is completed, as, for instance, when one competitor is four holes ahead with only three still to be played. When one player has a lead equal to the number of holes still unplayed, he is said to be *dormy* that number of holes; thus, a player when *dormy three* has a lead of three after playing the fourth last hole, in which case, though he may not win, he cannot lose. The central authority on the game in America regulating the various championships, etc., is the United States Golf Association organized 22 Dec. 1894, with which is now affiliated over 200 clubs throughout the country. Consult: Clark, 'Golf: A Royal and Ancient Game' (1899); Travis, 'Practical Golf' (1901); Richards, 'Royal Game of Golf' (1902).

Go'liad, Texas, city, county-seat of Goliad County; on the San Antonio River, and the Southern Pacific R.R., about 45 miles from the Gulf and 168 miles southwest of Galveston. Goliad gets its name from Hidalgo (q.v.), the patriot priest of Dolores, who in 1810 led the revolution in Mexico against Spain. When Goliad was founded the people did not dare to name it Hidalgo, so dropping the silent H and transposing the letters, they made the word Goliad. This place was the last site of the ancient mission of La Bahia del Espiritu Santo (1749). This mission was first founded at the place where La Salle built Fort Saint Louis in 1685. Goliad was the scene of a bloody contest (1812) between the so-called "Republican Army of the North," under Magee and Gutierrez, and the Mexicans. Here Magee died, evidently assassinated. In the Texas revolution (1835) Goliad was a point of strategical importance to the Texans. It was captured by Ben Milan and Collingsworth and became the base of military operations. The independence of Texas was declared here 20 Dec. 1835. Ira Ingram and Philip Dimmit were the leaders in formulating this declaration, and at the meeting there were 92 soldiers and all the citizens of the town. The official declaration of independence was made at Old Washington 2 March 1836. In Goliad, on Palm Sunday, 27 March 1836, the Mexican commander, Urrea, caused to be slaughtered 300 unarmed men who had surrendered, Fannin (q.v.) and his command. These defenseless men had been promised life and liberty before being marched out in squads and shot down like dogs. Urrea claimed he acted under orders from Santa Anna (q.v.). Afterward a rallying cry of the Texas troops under Sam Houston was "Remember Goliad." In 1902 Goliad was visited by a disastrous cyclone which swept away almost the whole town. Pop. 2,000.

Goliardery, gō'lĭ-är-dėr-ĭ, the name given to the *Carmina Burana,* a series of satirical Latin poems of the 13th century. They were the productions of the self-styled Goliardi, mediæval wandering students, disciples of the mythical Golias. While attacking the abuses and vices of the period, especially those existing in the Church, they glorified also the love of nature, women, and wine. This naturally antagonized the ecclesiastical mind which was prone to exaggerate into grave sins what ordinary men would consider as mere peccadilloes. From a classical standpoint the majority of the songs

are generally below criticism; from a moral point of view, many of them are vigorous and healthful, and are popular among German students of the present day. Consult: Schmeller, 'Carmina Burana' (1894); Symonds, 'Wine, Women, and Song' (1884).

Goli'ath Beetle, one of the huge scarabe beetles of the cetonian genus *Goliathus*, distinguished by their large size, the horny processes on the head of the male, and the teeth-bearing lower-jaws. The name specifically belongs to *G. giganteus* of the Gold Coast, which is four inches long, and is chalky-white broadly and variously marked with black. It feeds almost entirely on the sap of trees. Compare HERCULES BEETLE.

Golomyn'ka, or **Oil-fish**, a goby-like fish (*Comephorus baikalensis*) found only in Lake Baikal, about a foot long, destitute of scales, and very soft, its whole substance abounding in oil, which is obtained from it by pressure. It is never eaten.

Golosh'es (Fr. *galoche*, "a patten, clog, or wooden shoe") (1) a kind of wooden clog, with a joint at the instep and upper leathers like those of very low shoes, worn in the Middle Ages. (2) India-rubber overshoes first manufactured in the United States and introduced into Great Britain about 1847. The term is now restricted to the latter meaning, and is used mostly in England, very rarely in the United States. See INDIA-RUBBER; RUBBER MANUFACTURES.

Go'marists, the ultra Calvinistic party in the Dutch National Church, so called from their leader, Francis Gomar (q.v.).

Gomez, gō'mĕs, **Antonio Carlos**, Brazilian composer: b. Campinas 11 July 1839; d. Pará September 1896. He was a pupil at the Milan Conservatory, and had his first opera, 'A noite do castello,' presented at Rio de Janeiro in 1861. His 'Se sa minga' gained notable success at La Scala, Milan, in 1867, and was followed by a series of varying merit, including: 'Guarany' (1870); 'Salvator Rosa' (1874); and 'Lo Schiavo' (1889). He wrote the hymn 'Il saluto del Brasile' for the Centennial Exhibition at Philadelphia (1876), and a cantata, 'Colombo,' for the Columbian Exposition (1893). He was director of the Conservatory of Music at Pará, Brazil, 1895–6.

Gomez, Estevan, ĕs'tā-vän, Portuguese navigator: b. about 1474; d. about 1530. He became an expert pilot in the Portuguese East Indian fleet, sailed in 1519 on Magellan's voyage as pilot of the Trinidad and was later transferred to the San Antonio, on board which he contrived a successful mutiny and then sailed for Spain. There he was imprisoned, but in a short time set free. It appears that in 1524–5 he was sent by Charles V. to explore the eastern coast of what is now the United States and discover a northern route to the Orient. A map executed in 1529 by Diego Ribeira, a cosmographer, marks the territory included between the present States of Rhode Island and New Jersey, Tierra de Gomez.

Gomez y Baez, ē bä'ĕs, **Maximo**, Cuban soldier: b. Bani, Santo Domingo, 1831; d. Havana, Cuba, 17 June 1905. When Santo Domingo revolted against Spain he served as lieutenant of cavalry in the Spanish army; and when the freedom of the island was declared he went with the Spanish army to Cuba, but left the army because Gen. Villar maltreated some Cuban refugees. In 1868 he joined the Cuban insurrection, and through his ability and daring soon rose to a position of prominence, being in several successful engagements; though deprived of his command at one time, he was soon recalled, and rose to be major-general. On the failure of the rebellion, he left Cuba and settled on his farm in Santo Domingo. Returning to Cuba, he was influential in bringing about the insurrection of 1895–8, and was made commander-in-chief of the Cuban army. His policy was to avoid open engagements and to drive the Spaniards out by devastating the island and constant harrassing of their troops. When the American landed in Cuba (1898) he willingly co-operated with them. On 24 Feb. 1899 he marched into Havana at the head of his soldiers and was received by the United States authorities. In March of the same year he was deposed from his command by the Cuban Assembly on account of his accepting $3,000,000 for his army from the United States. He assisted the American governor-general in his work in the island, and was at one time suggested as a candidate for the presidency of the Cuban republic.

Gomez-Ferias, fā-rē'äs, **Valentin**, Mexican statesman: b. Guadalajara 14 Feb. 1781; d. Mexico City July 1858. He studied in the University of Guadalajara, was appointed a professor there in 1810, was a liberal member of the first constituent congress, was elected vice-president with Santa Anna, and in consequence of the latter's absence, assumed executive powers 1 April 1833. His administration was strongly opposed by the Clerical party; in 1835 a constitutional congress refused to acknowledge his authority, and he was exiled. He returned in 1838; in 1840 led an unsuccessful revolt, and again was banished. Having returned in 1845, he was elected vice-president in 1846; later a deputy to Congress, and was appointed postmaster-general under Alvarez.

Gompers, Samuel, American labor leader: b. London, England, 27 Jan. 1850. A cigar-maker by trade, he has been known as a zealous worker in the cause of the rights of labor, since his boyhood. He has been active in efforts to organize the working people, and was one of the founders of the American Federation of Labor, of which he is president. He has exerted much influence and has put forth various pamphlets on the labor question and the labor movement in general.

Gomuto, gō-moo'tō, a name in the East Indies for the stiff, strong fibre obtained from the leaves of the sugar-palm or areng (*Arenga saccharifera*) and hence often applied to the tree itself. This fibre, also called "ejow," is extensively used for ropes on account of its extraordinary strength and durability. At the base of the older leaves grows a woolly material called "baru," useful as stuffing for cushions, calking seams, and similar purposes. See PALM; SAGO.

Gonaives, gō-nä-ēv', Hayti, town on the west coast on the bay of the same name, 65 miles north-northwest of Port au Prince. It

has an excellent harbor, a naval and military hospital, and a mineral spring. The exports are cotton, coffee, salt, and mahogany. Pop. 18,000.

Gonas. See HOTTENTOTS.

Goncourt, de, dė gôṅ-koor, EDMOND LOUIS ANTOINE HUOT: b. Nancy 26 May 1822; d. 16 July 1896; and JULES ALFRED HUOT DE: b. Paris 17 Dec. 1830; d. Auteuil 20 June 1870; French novelists. The Goncourt brothers were not men of letters but artists primarily, and in 1849 they set out, knapsack on back, to traverse France for drawings and water-colors. Their note-books made them writers as well as artists, and already in 1852 they had commenced that literary partnership which continued nearly 20 years. Their earliest serious works were a group of historical studies upon the second half of the 18th century, intended to be an effective resurrection of its habits of life, manners, and costume, which, though elaborate in detail lacked calm and impartial historical sense, breadth of view, and creative grasp of character. These books were: 'Histoire de la Société Française pendant la Révolution' (1854), 'La Société Française pendant le Directoire' (1855); 'Portraits intimes du XVIII. Siècle' (1856–8); 'Histoire de Marie Antoinette' (1858); 'Les Maîtresses de Louis XV.' (1860), 'La Femme au XVIII. Siècle' (1862), and 'L'Amour au XVIII. Siècle' (1875); 'Gavarni' (1873), and 'L'Art au XVIII. Siècle' (1874). The more important work of the De Goncourt brothers was their novel writing; their conception of the novel was that it should be an imaginative attempt to grasp and summarize the results of close observation; their aim was to paint manners by taking the traits in which one man resembles a class; hence they select as generic types only persons of moderate faculties. Their novels include: 'Les Hommes de Lettres' (1860), republished in 1869 under the title 'Charles Demailly'; 'Sœur Philomène' (1861); 'Renée Mauperin' (1864); 'Germinie Lacerteux' (1865); 'Manette Salomon' (1867); and 'Madame Gervaisais.' After the death of his brother, Edmond wrote the 'La fille Elisa' (1878), a novel; 'L'Œuvre de Watteau' (1876); 'L'Œuvre de Prudhon' (1877); and 'La Maison d'un Artiste' (1881). Consult: Bellock and Shedlock, 'Edmond and Jules de Goncourt.'

Gon'dola, a long narrow boat used on the canals of Venice. The middle-sized gondolas are upward of 30 feet long and 4 to 5 feet broad; they always terminate at each end in a sharp point, which is raised perpendicularly to the ordinary height of a man. They have a well-furnished cabin amidship. They are propelled by rowing; the oarsman or gondolier stands in the stern facing forward; sometimes there are two gondoliers, the second one standing in the bow. They are usually painted black in accordance with an old law of the Venetian republic, which prescribed that all gondolas should be black, except those of the doge and the foreign ambassadors. The gondolas were until recently the only means of getting about the city; now steam-launches, acting as omnibuses, are also used.

Gonds, an aboriginal race of British India, a remnant of the Dravidians who were driven out of the plains by an early Aryan invasion. They took refuge in Gondawana, a territory pretty well identical with what are now called the Central Provinces. Here their seat was the Satpura plateau, between the rivers Pain Ganga, Pranhita and Godavari on the west and the Indravati on the east, while they were bordered on the north by the river Nerbudda. They still retain their dominion in the mountain forests of Orissa. Since 1781 they have become subjects of England, and their speech and religion have more and more conformed to those of the Hindu. Their language, known as Gondi, is a Dravidic branch of the Dekhan language. The contact with British civilization has not influenced them much in their highland lurking places. Their religion consists in a worship of many spirits, and they are enslaved to their priests. They have distinct physical characteristics which differentiate them from the Hindus. They are swarthy, almost black in complexion; their hair is long and black, though sometimes it is of a ruddy tinge. In countenance they have a broad forehead, and small, deep-set eyes. They wear little clothing. One of their clans, the Moria, tattoo their faces, and shave their heads. They do not like agriculture, but are much in demand as builders and roadmakers. According to the census of 1891 the total number of Gondi-speaking people in British India is 1,380,000, the majority of whom are found in the Central Provinces, the remainder being scattered through Bera and Hyderabad. Consult: Forsyth, 'Highlands of Central India' (1889); Dalton, 'Descriptive Ethnology of Bengal' (1872); Risley, 'Tribes and Castes of Bengal' (1892); Williamson, 'Gondi Grammar and Vocabulary.'

Gon'falon, an ensign or standard which used to be borne by the chief magistrates of many Italian cities, as Florence and Lucca. These magistrates were hence called gonfaloniers. The title of gonfalonier was also sometimes bestowed by the Roman Catholic Church on persons of distinction, who were called gonfaloniers of the Church.

Gong, an instrument of Chinese origin, made of a mixture of metals and shaped into a basin-like form, flat and large, with a rim a few inches deep. The sound of the gong is produced by striking it, while hung by the rim, with a mallet, which puts the metal into a state of vibration, and produces a loud piercing sound. The modern gong or gong-bell is sounded by striking it with a hammer operated by machinery.

Góngora, Luis de Góngora y Argote, loo-ēs' dā gōn'gō-rä ē är-gō'tā gōn'gō-rä, Spanish lyric poet: b. Cordova, 11 July 1561; d. there 23 May 1627. About 1614 he entered the Church, and became a prebendary of the cathedral at Cordova, and eventually chaplain to Philip III. Góngora's earlier writings — sonnets on a great variety of subjects, lyrical poems, odes, ballads, and songs for the guitar — are inspired with much true poetic feeling. His later works, consisting for the most part of longer poems, such as 'Solidades' (or Solitary Musings), 'Polifemo,' 'Pyramo y Thisbe,' are executed in an entirely different and novel style, characterized especially in respect of diction, by some of the same distinctive features

as are found in Euphuism in England and Chiabrerism in Italy. This later style of Góngora, which his followers and imitators designated the *stilo culto,* is florid, pedantic, full of Latin inversions and mythological allusions, pompous, and mannered, and in many places very obscure. His works were never published during his lifetime. The first edition was printed by his friend, Vicuña, in 1627. See Churton, 'Góngora' (1862).

Goniatites, go"nĭ-a-tī'tēz, a group of ammonites (q.v.), including the earliest forms characterized by the structure of the septa, which are lobed, but without lateral denticulations, as in the higher ammonites; they consequently exhibit, in a section, a continuous undulating line. Some forms with slightly waved septa approach very near to the Nautilus. The siphonal portion is shorter than the sides, forming a sinus at the back, as in the Nautilus. The last chamber, the one tenanted by the animal, occupies a whole whorl, and has besides a considerable lateral expansion. The shells are small, seldom exceeding six inches in diameter. This genus is confined to the Palæozoic strata.

Goniom'eter, a device for measuring the angles of crystals. The application goniometer may be likened to a protractor with a rotary radius. It is a semicircle hinged at 90°, to which are attached two arms of steel which are directly applied to the crystal whose angles are to be measured. Far more accurate is the reflecting goniometer, consisting of a graduated circle mounted either vertically or horizontally upon a stand with an apparatus for adjusting the crystal, and one or two telescopes; it determines through what angular space the crystal must be turned that two rays of light reflected in turn from two surfaces shall have the same direction.

Bonioph'olis, a primitive crocodile of the Jurassic Period. It is distinguished from modern crocodiles by several features, especially by the bi-concave vertebræ and the arrangement of the bony plates on the back. It once inhabited the Jurassic swamps and river-deltas in Europe and America, along with dinosaurs, turtles, etc. A complete skeleton is now exhibited in the Brussels Museum.

Gonorrhœa is perhaps the most universal and widespread of all diseases that affect the human race. Competent authorities have computed that fully three fourths of the adult male population and from one sixth to one third of the adult female population have contracted this disorder. The great majority of women who have gonorrhœa are reputable married women who have been infected by their husbands. Material as well as moral and sanitary conditions modify venereal morbidity. It is much greater in large centres of population than in suburban and rural communities.

Definition.— Gonorrhœa may be defined as a specific inflammation peculiar to certain mucous membranes, attended with the production of a purulent discharge. This discharge has the property of exciting a similar inflammation when brought in contact with other mucous surfaces susceptible to its action. The urethral mucous membrane in the male and the mucous membrane of the urethra, vagina, and cervix in the female are ordinarily the seat of gonorrhœal inflammation. Almost all mucous surfaces of the body, particularly the conjunctival mucous membrane, are susceptible to the irritant action of gonorrhœal pus.

Cause.— The cause of gonorrhœa is a specific micro-organism termed the gonococcus, which was discovered by Neisser in 1879. Inflammation of the urethra may result from a multiplicity of causes, chemical, irritant, and others, but true gonorrhœal inflammation has as its unique etiological factor the gonococcus.

The Gonococcus.— This micro-organism is a diplococcus; in shape each individual of a pair resembles a coffee bean — flat or slightly concave on one side and rounded on the other, with their flat surfaces opposed. The two hemispheres are separated by such a narrow interval that it is only recognizable under a lens of high power. The diplococci are grouped in pairs, fours, and other multiples of two. Their growth occurs by fissure, at right angles to the central interspace. The gonococci are always grouped in irregularly shaped columns, and are never met with in chains or pairs, as certain other micro-organisms. The differential characteristic of the gonococci is, that they quickly take a stain of aniline dyes and are more rapidly bleached than other micro-organisms. They may occur both within and without the pus and epithelial cells. In acute cases they are very numerous, but have a tendency to grow fewer with the decline of the inflammatory process. They are characterized by a marked longevity, are susceptible of existing in a latent state for an indefinite period, and are capable of being revived and exalted in virulence by local irritation which causes congestion of the parts, or when transferred to virgin tissues in which they find conditions favorable for their germination and growth. Numerous cases are on record where the gonococcus has been found still conserving all its virulence, and susceptible of being provoked into new activity by a variety of irritant causes years after infection.

Within the past two or three decades, our knowledge of gonorrhœa has undergone most marked and revolutionary changes. The old conception of gonorrhœa was that of a purely local disease, confined to the mucous tract in which it had its habitual origin, trivial in character, of limited duration, and entailing no serious consequences to the individual, except from neglected complications. The occasional occurrence of rheumatism, or of ophthalmia, which was recognized by the older observers, was thought to be due to the development of a latent rheumatic diathesis, to sympathetic inflammation, or simple metastasis. The idiosyncrasy of the patient was thought to play an important role in their production.

Since the discovery of the gonococcus, new facts have been developed, showing that instead of being limited to the genito-urinary tract, the range of its morbid action is much more extensive, and not infrequently is radiated to important internal organs. As a result of modern investigations, it may be positively affirmed that the gonococcus is susceptible of being taken up by the blood-vessels and lymphatics, and that it may affect almost every organ of the body. Staining and culture experiments have demonstrated its presence not only in the ovaries, tubes, and peritoneal cavity, which it reaches through invasion of the

intermediate mucous membrane, but also in the lining membrane of the brain and cord, of the heart, of the pleura, liver, spleen, kidneys, as well as the joints and tendinous sheaths.

The number, variety, and gravity of these systemic manifestations has led to the serious consideration of the question whether gonorrhœa is not to be classed as a constitutional affection. The cause or relation between these systemic affections and the gonococcus has been proven by the identification of the gonococcus in the lesions it has produced. These general effects have been also ascribed not simply to the pathogenetic action of the gonococci, but to their toxins and the presence of certain pyogenic microbes associated with the gonococcus.

Complications.— The more common complications of gonorrhœa are acute and chronic inflammation of the prostate and bladder and seminal ducts and vesicles, the cord and testes.

Gonorrhœal Arthritis.— One of the most important complications of gonorrhœa is seen in certain joint-affections, which are usually described under the term of gonorrhœal rheumatism. This complication usually occurs from the second to the third week of the disease, but may develop as early as the fifth or sixth day. Gonorrhœal arthritis manifests a remarkable affinity for the large articulations, as the knee and ankle joints, the hip and elbow. Only one joint may be involved, constituting what is termed mono-articular arthritis, or a number of joints may be involved, constituting poly-articular arthritis. In the latter case, different joints are more likely to be involved in succession, rather than simultaneously. As a result of the inflammation of the synovial membrane, which is particularly involved, there often occur serous, fibrinous, or purulent effusions. It is essentially a hydrarthrosis, and in most instances the disease is confined to the synovial membrane of the joint during the whole course of the affection. Gonorrhœal arthritis is usually chronic in duration, often lasting from two to three or for many months. In some cases it is chronic and practically indefinite. Anchylosis or immobility of the joint from rapid formation of adhesions is a not infrequent termination. Very often the tendinous sheaths, the bursæ and fascia may be involved.

Unfortunately the treatment of gonorrhœal rheumatism is extremely unsatisfactory. It does not seem to be susceptible to the curative action of remedies which are valuable in attacks of ordinary rheumatism. In quite a large proportion of cases there is more or less deformity or permanent disability.

Gonorrhœal Ophthalmia.— There is usually recognized a distinction between an ophthalmia which is due to a septic absorption, like gonorrhœal rheumatism, and that form of purulent conjunctivitis which is caused by direct transference of pus containing gonococci to the eye. The former never results from the direct inoculation of the contagious matter. Its symptoms are milder, and there are rarely changes which occasion adhesions or permanent injury to the sight. On the contrary, purulent conjunctivitis is due to the inoculation of the mucous membrane of the conjunctiva. The inflammatory process is characterized by greater intensity and rapidity of action, and not infrequently results in partial or complete loss of vision. Unless prompt and efficient treatment be at once instituted the cornea may rapidly ulcerate and slough, and prolapse of the contents of the globe of the eye may occur through the perforation. These changes are sometimes almost incredibly rapid, taking place in three or four days, exceptionally in 24 hours, and leading to complete destruction of vision. In the ophthalmia of the new-born, the eyes of the child are liable to be soiled with the uterine and vaginal liquids containing gonococci — one of the most frequent causes of blindness. It is estimated that from 10 to 20 per cent of all blindness is caused by gonococcic infection.

Gonorrhœa in Women.— Our knowledge of gonorrhœa in women is essentially a modern acquisition. Until within recent years it had never been the subject of serious and careful study. In the female the local and general effects of gonorrhœa are apt to be much more serious and permanent, owing to the extent and character of the structures exposed to infection. The greater extent of the genital tract permits a larger field for infection by direct continuity of tissue. The periodic vascular changes incident to the menstrual period, and the more pronounced modifications caused by pregnancy, exert a marked influence in accentuating the gravity of gonorrhœa in women. As a result of these changes gonococci, invading the uterine cavity and ascending along the tubes and ovaries to the peritoneal covering, produce peritonitis. Not only do these inflammatory changes imperil the life and health of the woman (which danger, in many instances, can only be averted by an operation involving the sacrifice of her reproductive organs), but they may absolutely extinguish her hope of children. Gonorrhœa is one of the most prolific causes of sterility. The inflammatory changes result in the blocking up of the channels of communication between the ovaries and the uterine receptacle of the ovum, thus preventing contact with the germinative spermatozoids. This mechanical obstacle to the passage of the ovum is, as a rule, permanent and irrelievable. It thus happens that the aptitude of the gonorrhœic woman for conception is often extinguished by the first pregnancy, the first child representing the sum total of her productive energy. In this connection, it may be said that one of the complications of gonorrhœa affecting the male (epididymitis) is a very frequent cause of sterility in men. Neisser believes that gonorrhœa in the male is responsible for 45 per cent of sterile marriages. The proportion of sterility due to the husband is variously estimated from 17 to 25 per cent, and almost the entire proportion of sterility in women is due to gonorrhœa communicated to her by her husband. The low birth-rate of married women is not, as is generally supposed, always voluntary, but it often proceeds from physical causes relating to the health or productive capacity of the married parties; it is not from choice, but from incapacity.

Gonorrhœa as a Social Danger.—Owing to its great frequency, the persistent vitality and virulence of its germs, even after apparent cure, and especially to the grave nature of the infection in women, and the serious menace to the health and even the life of the victim — to say nothing of its destructive effects upon the procreative functions — gonorrhœa is now regarded

by the medical profession as one of the most formidable social plagues of our age. Every year in this country thousands of young, innocent women are infected by their husbands, who in most cases are not aware that they carry with them the germs of a disease destined to wreck the health or lives of their partners. Many such women drag out a miserable existence of semi-invalidism, subject to painful or difficult menstruation, no longer able to walk freely, condemned to pass their days of suffering in a reclining position; and after years, it may be, of this suffering, worn out and desperate, they apply to the surgeon, who, at the price of the sacrifice of their generative organs, renders their existence possible in making them castrated women.

PRINCE A. MORROW, M.D.,
Author 'Relations of Social Disease and Marriage,' New York.

Gonsalvo de Cordova, gōn-säl'vō dė·kŏr'-dō-vä (Sp. gōn-thä'lō dā kŏr'dō-bä), in full GONSALVO HERNANDEZ DE CORDOVA Y AGUILAR, Spanish warrior: b. Montilla, near Cordova, 1453; d. Granada, 2 Dec. 1515. At the court of Ferdinand and Isabella, Gonsalvo attracted much attention by his personal beauty, his knightly skill, and the magnificence of his apparel and style of living. In the war with Granada, 1481–92, he took many places by storm, and vanquished the boldest Moors who dared to meet him in single combat. He was selected to carry on the difficult and dangerous negotiations with the Moorish king Abu Abdallah (or Boabdil), which resulted in the capitulation of Granada and the termination of Moorish rule in Spain. He helped Ferdinand II., king of Naples, to drive the French over the Neapolitan frontiers, and in 1500 delivered Zante and Cephalonia from the Turks and restored them to Venice. In the war between France and Spain, for the sovereignty of Naples, Gonsalvo gained successive victories, until by the fall of Gaëta, the French were forced to yield their claim upon Naples. Ferdinand now bestowed upon him the duchy of Sessa, and appointed him viceroy of Naples, with unlimited powers, which post he held until 1507, when the jealousy of the king caused his removal.

Gontcharoff, gŏn-chä-rŏf, **Ivan Alevander,** Russian novelist: b. Semborsk 18 June 1813; d. St. Petersburg 27 Sept. 1891. He studied at the University of Moscow, obtained a post in the finance ministry in 1835; published his first book, 'A Common Story' in 1837; subsequently was appointed an official in the censor's department, and then, until his retirement in 1873, was editor of the *Northern Post,* a government newspaper. His 'Oblomov' (1858), "a personification of that generic apathy which was, and still is, the common product of the material and moral conditions of Russian life," is his best work. He wrote also 'The Precipice' (1868) and some sketches.

Gon'ville and Caius (kēz) **College,** a college of Cambridge University, England, was founded in 1348 by Edmund Gonville of Terrington, Norfolk, and endowed for a master and three fellows. The original site was between Free School Lane and the churchyard of St. Botolph's. In 1353 William Bateman, bishop of Norwich, Gonville's executor, established the college where the Gonville Court at present stands, and altered the name to the Hall of the Annunciation of Blessed Mary the Virgin. In 1558 Dr. Caius obtained the royal charter by which all the former foundations were confirmed and his own foundation was established. By this charter the college was thenceforth to be called Gonville and Caius College. New statutes were given by which the college is henceforth to consist of a master, 30 fellows, and 36 scholars. The fellowships are all open, and are not vacated by marriage, but terminate generally at the end of 10 years from the full standing of M.A. The scholarships are also open. There are also connected with this college four studentships in medicine, founded by Charles Tancred, and two Harrow scholarships.

Gonzaga, gōn-zä'gä, **Thomaz Antonio Costa de,** Brazilian poet; called the Portuguese Anacreon: b. Oporto, August 1744; d. Mozambique 1809. After studying in the university of Coimbra, Portugal, he returned in 1768 to Brazil to enter on an official career. In 1788 he was about to marry a young lady of distinguished beauty when he became involved in a political conspiracy. The court condemned him to perpetual exile in an island on the coast of eastern Africa, which by special favor was commuted to 10 years' banishment to Mozambique. He left Brazil in 1793, and was attacked by fever soon after reaching Africa, from which he recovered only to fall into madness from the effect of the climate. The most interesting of his poems were composed during his captivity, and celebrate in mournful and tender verse the object of his love under the name of Marilia. They are popular alike in Brazil and Portugal, and have been often reprinted. In grace, tenderness, purity of style, and harmony of verse, Gonzaga ranks among the first Portuguese poets.

Gonzaga Family, a noted Italian family which held the supremacy in Mantua 1328–1707. On 14 Aug. 1328 LUDOVICO (or LUIGI GONZAGA) assumed the sovereignty after his sons had driven out the Bonacorsi family and taken possession of Mantua. He died 1360, aged 93. Among his descendants, GIAN FRANCESCO GONZAGA, in 1432, obtained possession of the city, with its territory, under the title of a marquisate, as a fief from the Emperor Sigismund. With VINCENZO II., the reigning line became extinct in 1627. The next heir would have been the Duke of Nevers, but the Duke of Guastalla, Ferdinand II., one degree more remote, laid claim to the whole inheritance, and Charles Emmanuel, Duke of Savoy, claimed Montferrat. It was evident that the house of Nevers had a legal right, and France, Venice, and the Pope supported him. Spain and Austria, on the other hand, supported the groundless claims of the Duke of Savoy, whence arose a war concerning the Mantuan succession, which ended with the triumph of Charles, Duke of Nevers. His grandson, CHARLES III., succeeded him in 1637, and during his reign the principality obtained full independence. He died in 1665. Many persons of this family have obtained military renown. Others have been conspicuous for their love of the arts and sciences. CÆSAR, in 1565, erected the academy Degl'invaghiti; and others of the family founded galleries of paintings and

antiquities. Giulio Romano, under their patronage, established an extensive school for painting, and many celebrated artists received from them support and honor.

Gonzalez, gōn-sä'lĕs, **Manuel,** Mexican soldier and statesman: b. near Matamoros 18 June 1833; d. Mexico City 8 May 1893. He entered the army in 1839 and fought under Juarez in 1861. In the war against the French he joined Escobedo in 1865 and was made a brigadier-general. Later he joined the party of Diaz and was secretary of war under him 1877–80, and followed him as president of the Mexican republic 1880–4. After his retirement he was governor of Guanajuato.

Goober, or **Gouber.** See PEANUT.

Gooch, SIR **Daniel,** English engineer: b. Bedlington, England, 24 Aug. 1816; d. Clewer Park, England, 15 Oct. 1889. Besides inventing various improvements in the building of locomotives, he was active in furthering the laying of the first transatlantic cable. He sat in Parliament 1865–85, and was connected with the Great Western Railway as a superintendent 1837–64.

Gooch, Frank Austin, American chemist: b. Watertown, Mass., 2 May 1852. He was educated at Harvard and was assistant in the chemical laboratory there, 1872–5. He was subsequently chemist on the Northern Transcontinental Survey and United States Geological Survey, 1878–86, and has been professor of chemistry at Yale from 1886.

Gooch, SIR **William Bart,** English colonial administrator: b. Yarmouth 21 Oct. 1681; d. London 17 Dec. 1751. He was a soldier of Marlborough in the Netherlands, and was governor of Virginia from 1727 to 1747. In 1740 he accompanied Vernon's expedition against Cartagena, and in 1749, after a generally excellent and successful administration, returned to England. During his term of office he opposed religious toleration to religious organizations other than the Establishment.

Good, James Isaac, American (German) Reformed clergyman: b. York, Pa., 31 Dec. 1850. He was graduated from Lafayette College, Easton, Pa., in 1872; entered the Reformed ministry and has been successively pastor of Heidelberg Reformed Church, York, Pa., 1875–7; Heidelberg Reformed Church, Philadelphia, 1877–90; and Calvary Reformed Church, Reading, Pa., 1890–3. Since the last named year he has been professor of dogmatics at Ursinus College. He has published: 'Origin of the Reformed Church of Germany' (1887); 'Rambles Round Reformed Lands' (1889); 'History of the Reformed Church in the United States.'

Good, John Mason, English physician and author: b. Epping, Essex, 25 May 1764; d. Shepperton, Middlesex, 2 Jan. 1827. In 1793 he removed to London, where he carried on business for several years as a surgeon and apothecary, and after 1820 practised as a physician. His principal works are: 'Memoirs of the Life and Writings of Dr. Alexander Geddes' (1803); Translations of Solomon's Song and the Book of Job; a translation of Lucretius 'On the Nature of Things' (1805); 'Medical Technology' (1810); 'A Physiological System of Nosology' (1817); 'The Study of Medicine' (1822); and 'The Book of Nature' (1826).

Good Friday, the name applied by the Church of England to the Friday before Easter, sacred as commemorating the crucifixion of our Lord; the Great and Holy Parasceve is the Greek title of it, and it is called in the Roman Missal the Parasceve. This day was kept as a day of mourning, of rigid fast, and of special prayer from a very early period. Eusebius (260 A.D.) says that the day had been observed long before his time. Constantine ordered a cessation from all labor on that day. It was one of the two paschal days celebrated by the Christian Church, and in memory of the crucifixion was called by the Greeks Pascha Staurosimon or the "Pasch of the Cross." In the Roman Catholic Church the service of this day consists of what is called the Mass of the Presanctified, the sacred host not being consecrated on Good Friday, but reserved from the preceding day. Communion is forbidden on Good Friday, except in the case of the celebrant and of sick persons.

The most striking part of the ceremonial is the so-called "adoration of the cross," or, as it was called in the Old English popular vocabulary, "creeping to the cross." The black covering is removed from a large crucifix which is placed before the altar, and the entire congregation, commencing with the celebrant priest and his ministers, approach, and on their knees reverently kiss the figure of our crucified Lord. The very striking office of *Tenebræ* (darkness) is held on Good Friday, as well as on the preceding two days: it consists of the matins and lauds of the following day, and has this peculiarity, that by the close all the lights in the church have been gradually extinguished except one, which for a time (as a symbol of our Lord's death and burial) is hidden at the Epistle corner of the altar.

In the Church of England, and in the Protestant Episcopal Church of the United States, as well as in the Roman Catholic Church, Good Friday is celebrated with special solemnity: proper psalms are appointed, and one of the three special collects is a prayer for "all Jews, Turks, infidels, and heretics." In some churches of the English Church, and of the Protestant Episcopal Church, the *improperia,* or reproaches, adopted from the Roman service, are sung; and Bach's passion music is frequently heard. In England and Ireland Good Friday is by law a *dies non,* and all business is suspended; but this is not the case in Scotland or the United States. In Scotland the day till recently met with no peculiar attention, except from members of the Episcopal and Roman Catholic communions; but of late years there have been services in some Presbyterian churches in the larger towns.

A German savant, Prof. Hans Achelis of Königsberg, has decided on the basis of exact calculations made by the Royal Astronomical Society of Berlin that the date of the Crucifixion was 6 April 30 A.D.
